The thinner used may have the following composition:

	Per cent.
Ethyl acetate	25
Butyl acetate	25
Butyl alcohol	10
Toluol	20
Xylol	20
	100

In preparing this lacquer #1, the following procedure may be followed, although the lacquer may also be prepared in various other ways:

Seventy-five parts by weight of a nitrocellulose base solution (*a*), containing a reduced viscosity nitrocellulose whose viscosity lies between 500 and 1500 centipoises in 16 oz. C. P. ethyl acetate solution, is mixed with thirteen parts by weight of a resin solution to give the necessary resin content as shown above. Softener and toluol are added and the whole mixed until thorough incorporation is produced. A clear dark amber colored solution should be produced.

The nitrocellulose base solution referred to in the preceding paragraph has the following composition:

	Per cent.
Butyl acetate	35
Butyl alcohol	11
Ethyl acetate	12
2-B denatured alcohol	16
Acetone	3
Methyl alcohol	6
Pyroxylin	17
Total	100

An ordinary barrel type of mixture is used in making up this solution. The nitrocotton, having a viscosity of about 35,000 centipoises, plus .8% of its weight of crystalline sodium acetate is added to the mixer, care being taken that there is a thorough intermixing of the salt and nitro-cotton. The solvents are then added, and the whole thoroughly mixed until an easily flowing solution is obtained. This solution is then run into barrels which are placed in a closed room maintained at 38–40° C. Samples are taken from these barrels from time to time and viscosity measurements make until the difference between separate viscosity measurements indicates that the reducing action has practically ceased. This has been found by experience to require about four to six weeks for this type of mixture. When this point is reached the barrels are withdrawn from the heated room and stored at ordinary room temperature until such time as the contents are needed for use in regular mixtures. The nitrocellulose component of the reduced viscosity solution, when isolated, and dissolved in C. P. ethyl acetate, forms a solution having a viscosity of about 600 to 700 centipoises at 28° C.

The resin solution may be prepared in the usual way by dissolving the resin to be used (e. g. dammar, shellac, or elemi) in a solvent mixture in which it dissolves readily, and which mixes readily with the nitrocellulose base solution, and separating the clear solution by decantation after the insoluble portion has settled.

Example 2.

Another typical lacquer coming within the scope of my invention has the following composition:

Lacquer #2.

	Per cent.
Nitrocellulose of reduced viscosity	18.30
Butyl acetate	23.40
Ethyl acetate	9.60
Butyl alcohol	5.40
Denatured alcohol	12.40
Acetone	1.70
Methyl alcohol	3.90
Resin or gum	5.80
Benzol	1.80
Toluol	12.70
Dibutyl phthalate	5.00
Total	100.00

The viscosity of the above described lacquer No. 2 as measured by the Stormer viscometer at 28° C. is between 1300 and 1500 centipoises. When thinned by adding 40 parts of thinner to 60 parts of lacquer the viscosity is between 100 and 300 centipoises.

In the above described lacquer #2 there may be used for the resin constituent any of the resins or gums mentioned above; and in place of dibutyl phthalate, other solvent softeners may be used.

The pyroxylin used in lacquer #2 has an average viscosity below 400 centipoises, and preferably of about 300 centipoises. This low average viscosity pyroxlyn is prepared by mixing twenty-one (21) parts by weight of the nitrocellulose base solution (*a*) described in connection with lacquer #1 (said base solution containing 17% of nitrocellulose having a viscosity of about 625 centipoises), with about forty-nine (49) parts of a base solution (*b*) of practically the same solvent composition as base solution (*a*) but containing 30% of nitrocellulose whose 16 oz. C. P. ethyl acetate solution has a viscosity of about 160 centipoises.

A nitrocellulose base solution (*b*), containing nitrocellulose whose 16 oz. C. P. ethyl acetate solution has a viscosity of between 90 and 340 centipoises when measured by the Stormer viscometer at 28° C., may be produced by dissolving in a solvent com-

1029

position a soluble nitro-cotton whose 16 oz. C. P. ethyl acetate solution has a viscosity of about 35000 centipoises at 28° C., to form a solution having the following composition:

	Per cent.
Butyl acetate	33.30
Butyl alcohol	5.70
Acetone, C. P	2.30
Ethyl acetate	11.30
Methyl alcohol, (99%)	5.40
2–B denatured alcohol	12.00
Nitrocellulose	30.00
	100.00

and subjecting the nitro-cotton in this solution to the action of sodium acetate. The detailed procedure for making base solution (*b*) is exactly similar to that described above for making base solution (*a*), except that the sodium acetate added is equal to 2% of the weight of the nitrocotton used. The time necessary to obtain the required reduction in viscosity is two to three weeks at 38–40° C.

To manufacture the lacquer, the following procedure is followed:

Forty-nine parts by weight of the 30% base, and twenty-one parts by weight of the 17% base are mixed with twelve and one-half parts by weight of a resin solution, and the necessary amounts of dibutyl phthalate and toluol added. The whole is mixed until a clear dark amber solution is obtained, and it is then ready for application. Reduced to formulation on this basis the composition reads:

	Per cent.
30% base	49.00
17% base	21.00
Resin solution	12.50
Dibutyl phthalate	5.00
Toluol	12.50
	100.00

Although the viscosity of my new coating compositions when ready for use as dip or spray lacquers or enamels, is from about 100 to 300 centipoises, I preferably employ a nitrocellulose whose viscosity-characteristic is such that the finished coating composition will have a viscosity of about 125 centipoises, the nitrocellulose content being above 9%, and, more specifically, a coating composition, with the above approximate viscosity having a nitrocellulose content above 7% and a total solids content, exclusive of pigment, above 15%.

Example 3.

Where an enamel is to be prepared a pigment is incorporated in the coating composition, the percentage of pigment being usually between 5 and 30% based upon the weight of the finished enamel. As suitable pigments there may be mentioned zinc oxide, lithopone, titanium oxide, blanc fixe, ultramarine blue, and carbon blacks. Other mineral pigments and lakes in general may be used. A typical enamel illustrative of my invention has the following composition, the viscosity of the nitrocellulose used therein being between 400 and 1500 centipoises in 16 oz. ethyl acetate solution:

	Per cent.
Pigment	9.00
Pyroxylin	10.50
Resin or gum	7.60
Dibutyl phthalate	6.50
Butyl acetate	21.60
Butyl alcohol	7.20
Ethyl acetate	8.60
Denatured alcohol	15.90
Acetone	1.70
Methyl alcohol	3.90
Benzol	8.40
	100.00

This enamel will show a viscosity in the neighborhood of 1,000 centipoises and will have to be thinned in the neighborhood of 30% of thinner and 70% of enamel to obtain spraying viscosity.

The volatile solvents employed in these high percentage pyroxylin, low viscosity coating compositions are chiefly acetone, acetone oils, the lower alcohols (methyl, ethyl, etc.) and the lower alkyl acetates, such as ethyl, propyl, butyl, and amyl acetates. As diluents there may be used the volatile petroleum hydrocarbons, and the benzenoid hydrocarbons such, for example, as benzene and toluene. I have found it advantageous to employ low boiling alcohols and certain high boiling esters or ketones, such as butyl acetate, in approximately the proportions described; that is, the low boiling alcohols approximately in the same proportion as the nitrocellulose and the high boiling esters or ketones approximately from an equal proportion to about three times the proportion of nitrocellulose. I have found it advantageous to have the proportion of resin or gum in many cases approximately two-thirds to one-half that of the nitrocellulose and the solvent softener approximately one-third to one-seventh that of the nitrocellulose as shown by the foregoing examples, although some deviation may be made from these proportions. The proportion of pigment will vary from 5 to 30% as stated previously, according to the nature of the lacquer or enamel desired to be produced, and the quality of pigment; as shown by the examples, the proportion is preferably 5 to 9 parts for 10 or 12 of nitrocellulose.

The viscosity values herein mentioned are values obtained at 28° C., with a 500 g. weight, with the aid of the Stormer viscometer, and, in the cases of nitrocellulose, they

1020

are the values of a 16-oz. chemically pure ethylacetate solution thereof. The viscosity characteristic of the nitrocellulose employed in the foregoing compositions should be below 1500 centipoises when employing low viscosity nitrocellulose, and will often preferably be below 400 centipoises. In view of the favorable action of sodium acetate or its equivalents in reducing the viscosity of nitrocellulose, as herein described, there will be no disintegration thereof so as to reduce the nitrogen content to too low a figure, and it is therefore unnecessary to specify a lower value for the viscosity characteristic, but such may be well below 400 or even 100 centipoises.

The films produced from the lacquers and enamels described above will be hard, durable, tough, adhesive, and relatively non-shrinking. The films will, as before stated, be used to form relatively thick coats on rigid surfaces, and owing to the presence of solvent softeners, they will have good flexibility and the non-softeners will reinforce the low viscosity nitrocellulose (which is relatively very low), so that both materials will cooperate in providing a film which will not become brittle on aging and not show such signs of deterioration as might be shown by a low viscosity film containing no solvent softener. The presence of resins also materially enhances the quality and adhesion of the films, and thus, in conjunction with the solvent softeners, provides a film not heretofore produced. By the addition of pigments in the relative proportions described, a successful colored film may be produced.

As many apparently widely different embodiments of this invention may be made without department from the spirit thereof, it is to be understood that I do not intend to limit myself to the specific embodiments thereof except as indicated in the appended claims.

I claim:

1. A nitrocellulose coating composition comprising in combination nitrocellulose whose viscosity characteristic is such that a 16-oz. C. P. ethyl acetate solution thereof has a viscosity at 28° C. of below 1500 centipoises; and a solvent softener for the nitrocellulose.

2. A nitrocellulose coating composition comprising in combination nitrocellulose whose viscosity characteristic is such that a 16-oz. C. P. ethyl acetate solution thereof has a viscosity at 28° C. of below 400 centipoises; and a solvent softener for the nitrocellulose.

3. A nitrocellulose coating composition comprising in combination a reduced viscosity nitrocellulose whose viscosity characteristic is such that a 16-oz. C. P. ethyl acetate solution thereof has a viscosity at 28° C. of below 1500 centipoises; a solvent softener for the nitrocellulose having a melting point below 50° C. and being non-volatile.

4. A pyroxylin coating composition having a viscosity of between 100 and 300 centipoises at 28° C., and containing more than 9% of nitrocellulose, a volatile nitrocellulose-solvent, and a solvent softener for the nitrocellulose, the viscosity-characteristic of said nitrocellulose being such that a 16-oz. C. P. ethyl acetate solution thereof has a viscosity at 28° C. of less than 1500 centipoises.

5. A pyroxylin lacquer comprising, in combination, nitrocellulose, a substantially non-volatile solvent softener therefor, and a gum, said nitrocellulose having a viscosity characteristic which, when expressed in terms of the viscosity of a 16 oz. C. P. ethyl acetate solution thereof, is less than 1500 centipoises.

6. A lacquer as defined in claim 2 in which the softener comprises dibutyl phthalate.

7. A pyroxylin enamel comprising nitrocellulose, a solvent softener therefor, a pigment, and a gum, the viscosity-characteristic of the nitrocellulose, expressed in terms of the viscosity of a 16 oz. ethyl acetate solution thereof, being below 400 centipoises.

8. A coating composition comprising a low viscosity nitrocellulose having a viscosity characteristic below 1500 centipoises as defined; a solvent softener in the proportion of about two-thirds to one-seventh of the nitrocellulose; and a resin in the proportion of less than one-half of the proportion of the nitrocellulose.

9. A coating composition comprising a low viscosity nitrocellulose having a viscosity characteristic below 1500 centipoises as defined; a solvent softener in the proportion of about one-seventh to two-thirds that of the nitrocellulose; a resin less than one-half that of the nitrocellulose; and a low boiling alcohol in about the same proportion as the nitrocellulose.

10. A coating composition comprising a low viscosity nitrocellulose having a viscosity characteristic below 1500 centipoises as defined; a solvent softener in the proportion of about one-seventh to two-thirds that of the nitrocellulose; a resin less than one-half the proportion of the nitrocellulose; a low boiling alcohol in about the same proportion as the nitrocellulose; and a high boiling ketone or ester in a proportion from about one to three times that of the nitrocellulose.

11. A coating composition comprising a low viscosity nitrocellulose having a viscosity characteristic below 1500 centipoises as defined; a solvent softener from about one-seventh to two-thirds the proportion of the nitrocellulose; and a resin in less than one-half the proportion of nitrocellulose.

12. A coating composition comprising a

low viscosity nitrocellulose having a viscosity characteristic below 1500 centipoises as defined; a resin, and a pigment; the proportion of the resin being less than half that of the nitrocellulose, and the proportion of pigment being from 5 to 30 parts for about 12 of the nitrocellulose.

13. A coating composition comprising a low viscosity nitrocellulose having a viscosity characteristic below 1500 centipoises as defined, a resin, a solvent softener, and a pigment; the proportion of resin being less than half that of the nitrocellulose, the proportion of softener being from one-seventh to two-thirds that of the nitrocellulose, and the proportion of pigment being from 5 to 30 parts for about 12 of the nitrocellulose.

14. A coating composition comprising a low viscosity nitrocellulose having a viscosity characteristic below 1500 centipoises as defined, in the proportion of about 10 parts; a resin less than 5 parts; a pigment 5 to 9 parts; a solvent softener from 2 to 7 parts; a small proportion of non-drying oil, but substantially no drying oil; and solvents to provide a flowable or spraying lacquer.

15. A coating composition comprising a low viscosity nitrocellulose having a viscosity characteristic below 1500 centipoises as defined, in the proportion of about 10 parts; a solvent softener from 2 to 7 parts; a pigment 5 to 9 parts; and solvents to provide a flowable or spraying lacquer.

16. An article coated with a hard, durable, tough, adhesive, film containing nitrocellulose whose viscosity characteristic is below 1500 centipoises as defined, and a solvent softener.

17. An article coated with a hard, durable, tough, adhesive, substantially non-shrinking film containing nitrocellulose whose viscosity characteristic is below 1500 centipoises as defined, a solvent softener, and a resin.

18. An article coated with a hard, durable, tough, adhesive, substantially non-shrinking film containing nitrocellulose whose viscosity characteristic is below 400 centipoises as defined, and a solvent softener.

19. An article coated with a hard, durable, tough, adhesive, substantially non-shrinking film containing nitrocellulose whose viscosity characteristic is below 1500 centipoises, a solvent softener in the proportion of one-seventh to two-thirds that of the nitrocellulose, and a pigment in the proportion of 5 to 9 parts for 12 of nitrocellulose.

20. An article coated with a hard, durable, tough, adhesive, substantially non-shrinking film containing nitrocellulose whose viscosity characteristic is below 1500 centipoises, a resin in the proportion of less than half that of the nitrocellulose, and a pigment in the proportion of 5 to 9 parts for 12 of nitrocellulose and a solvent softener.

21. An article coated with a hard, durable, tough, adhesive, substantially non-shrinking film containing nitrocellulose whose viscosity characteristic is below 1500 centipoises, a solvent softener in the proportion of one-seventh to two-thirds that of the nitrocellulose, a resin in the proportion of less than half that of the nitrocellulose, and a pigment in the proportion of 5 to 30 parts for 12 of nitrocellulose.

In testimony whereof I affix my signature.

MAURICE VALENTINE HITT.

CERTIFICATE OF CORRECTION.

Patent No. 1,710,453. Granted April 23, 1929, to

MAURICE VALENTINE HITT.

It is hereby certified that error appears in the printed specification of the above numbered patent requiring correction as follows: Page 1, line 35, for the word "be" read "been"; page 3, line 39, for the word "mixture" read "mixer"; page 5, line 24, for the compound word "non-softeners" read "solvent softeners"; and that the said Letters Patent should be read with these corrections therein that the same may conform to the record of the case in the Patent Office.

Signed and sealed this 11th day of June, A. D. 1929.

M. J. Moore,
Acting Commissioner of Patents.

J. J. BYERS.

SHEFT MATERIAL AND METHOD OF TREATING THE SAME.

APPLICATION FILED JAN. 10, 1917.

1,325,075. Patented Dec. 16, 1919.

Inventor:
Joseph J. Byers,
by Emery Booth Janney & Varney
Attys.

UNITED STATES PATENT OFFICE.

JOSEPH J. BYERS, OF BROOKLINE, MASSACHUSETTS, ASSIGNOR TO PRODUCTS SYNDICATE, INC., OF BOSTON, MASSACHUSETTS, A CORPORATION OF MASSACHUSETTS.

SHEET MATERIAL AND METHOD OF TREATING THE SAME.

1,325,075. Specification of Letters Patent. Patented Dec. 16, 1919.

Application filed January 10, 1917. Serial No. 141,667.

To all whom it may concern:

Be it known that I, JOSEPH J. BYERS, a citizen of the United States, and a resident of Brookline, county of Norfolk, State of Massachusetts, have invented Improvements in Sheet Materials and Methods of Treating the Same, of which the following description, in connection with the accompanying drawings, is a specification, like characters on the drawings representing like parts.

This invention relates to the art of applying a sheet or layer of material to another, for the purpose of imparting thereto certain desirable qualities, as well as to the improved product obtained by said method. The invention is applicable to any sheet material, but the invention contemplates more particularly the application thereof to textile or other fibrous materials, such as leather for example, at least one of the sheets having preferably been treated so as to impart thereto wear-resisting and other advantageous qualities.

The invention will best be understood from the following description, taken in connection with the accompanying drawing, of one illustrative product of my improved method, and of the best mode or manner known to me for practising such method, while its scope will be more particularly pointed out in the appended claims.

The accompanying drawing shows one improved product embodying my invention.

Referring to the drawing, the sheet of material 1 therein illustrated is given merely as an example of any textile or other fibrous material, such as leather for example, to which it is desired to apply another wear-receiving sheet 2.

The outer or wear-receiving sheet will preferably be treated to render the same water-repellent and highly wear-resisting, and is then so applied to the other sheet 1 as to constitute a homogeneous, wear-resisting layer.

Any suitable material may be taken as a basis for the wear-receiving sheet 2, but preferably this will be of some fibrous material such as a textile fabric or leather. Certain materials, such as ordinary grades of chrome-tanned leather for example, which, owing to their porosity, lack of body and tendency to stretch when moist are not adapted for certain uses where wear-resisting or other special qualities are required, will, when treated by my process, become suitable for such uses.

The sheet material 2 which is to constitute the wear-receiving sheet or member is preferably treated with a cement-like substance consisting of or including a cellulose derivative in solution and containing a quantity of non-oxidizing oil. This treatment is carried out in such a manner as to impregnate the material throughout with the oil-containing cement. This cement-like substance, containing a cellulose derivative and a non-oxidizing oil, will hereinafter be referred to briefly as the cement.

The materials composing the cement and the proportions in which they are mixed may be varied within wide limits. A suitable cement, for example, may be prepared by dissolving some cellulose derivative, a soluble nitrocellulose for example, in a suitable solvent, which may be acetone and alcohol in equal parts; if, for illustration, soluble nitro-cellulose and acetone and alcohol are used, one pound of soluble nitro-cellulose to one gallon of solvent may be employed with good results. To this is added a substantial amount of some non-oxidizing or non-drying oil, preferably a vegetable oil. This, for example, may be castor oil in the proportion of eight ounces to one pound of soluble nitro-cellulose.

The preferred method of impregnation is by immersing the material in a bath composed of the cement. For illustration, a bath may be prepared of sufficient volume and proportion to the mass of the material to be treated to maintain the material immersed for the required time thoroughly to impregnate it without impairing the fluidity of the bath or effectiveness of the treatment. The tank or other receptacle employed for the bath is closed to prevent any substantial evaporation of the solvent during the treatment of the material and is also provided with suitably controlled heating means so as to maintain the bath at a suitable temperature.

The temperature of the bath is preferably maintained at a point above the normal temperature of the air but below that which would rapidly evaporate the solvent or impair the material to be treated. In the treatment of leather with a cement constituted as described and containing the stated amount of castor oil, the temperature should

Page Tightly Bound

1035

be preferably less than 150° F. Good results are obtained with temperatures varying from 125° to 130° F.

Porous materials such as leather usually hold absorbed more or less hygroscopic moisture. To facilitate the impregnation of the material with cement, it is preferable to remove substantially all water and hygroscopic moisture from the material before its treatment. This may be accomplished in any suitable or desirable manner, but, in the case of leather, a simple method is to expose the material to a suitable drying temperature for a period long enough to drive out the moisture. The time and temperature required will differ for different materials and for different masses of the same material. In the case of leather, for example, the leather may be hung or spread over night in a drying room or a drying oven at a temperature of from 120° to 150° F. In the case of some textile fabrics or thin sheet material, the material may be prepared for immersion by passing the same slowly through a drying room or drying apparatus.

Preferably also the material should be handled and the treatment carried out in a room where the air has a low humidity, so that in passing from the drying operation to the immersion, the material may have no opportunity to absorb or collect any substantial or detrimental amount of moisture.

By expelling substantially all the moisture in the leather or other material, and immersing it while in a dry state, the permeation or impregnation of the material is facilitated and it is possible to impregnate the entire mass with the cement.

With the material dried as described, it may be immediately plunged into the bath and there maintained immersed in the presence of heat for a long enough period thoroughly to impregnate it with the cement.

The period during which the immersion may be profitably continued will vary with the material and its thickness. For sole or similar leather, for example, several minutes to several hours may be required, according to thickness. In the case of some thin, permeable material, a few minutes will sometimes be sufficient. The immersion is continued for an appreciable period, sufficiently prolonged to impregnate the material throughout. In the presence of heat and immersed in the solution, the material becomes thoroughly impregnated with the cement.

The material treated by this method will be thoroughly impregnated throughout as distinguished from a mere surface coating or a coating which has a mere anchorage or impregnation of limited depth. Leather thus treated acquires the property of repelling water, has great durability and density and a high degree of flexibility.

Furthermore, the water-repellent properties and flexibility are long continuing, which I attribute to the fact that the oil which is sealed into the fibers or particles by the cement cannot be washed out by exposure to moisture. When ordinary leather becomes wet and is thereafter dried by exposure to heat, it loses its softness and flexibility, becomes dry and hard and cracks readily. This is largely due to the fact that the oil, soap or grease contained in the leather has been in part washed out by the wetting of the leather and in part driven out by the subsequent application of heat for drying the leather. Leather treated by my present method and which has become damp can be readily dried by the application of heat without becoming hard or stiff and without losing its flexibility and water-repellent properties, which I also attribute to the fact that the oil is sealed into the individual fibers or particles by the cement and cannot be driven out by the heat used to dry the leather.

It will thus be seen that leather treated by my process appears to have an oil-flexed property which is substantially permanent while the oil commingled with the cement throughout the body gives it a high degree of permanent flexibility and water-repellent property.

After removing the material from the bath, it is dried, the effect of this is apparently to unite the fibers or particles into a homogeneous mass, leaving the oil sealed in the particles or fibers and protected by the cement, which as I believe, incases them and binds them together throughout.

The impregnated sheet material need not necessarily be absolutely dry but the drying should be sufficient to set the cement at least near the surface, and it is then ready to be applied to other material, to serve, for example, as a wear-receiving member or lave in respect to the latter. This will preferably be by cementing it thereto. Where the material treated in accordance with my process is applied directly to another material, for example leather or other fibrous material which has not been so treated, that face of the latter to which my treated material is to be applied will preferably be roughened up so as to open up the fibers and permit the penetration of the cement solution used to a sufficient depth to secure a firm anchorage.

As an illustrative method of applying a fibrous material, leather for example, treated by my above-described process to material, either leather or other fibrous material not so treated, the following may serve: One surface of the untreated material having been roughened as above stated the same is covered with a cement solution and a similar solution is applied to one face of the cement-impregnated material. Pre-

Page Tightly Bound

erably both materials should be warm and dry before application of the cement and the operation should preferably be carried out in a dry atmosphere. The cement employed for this coating is preferably a cement which contains a cellulose derivative and oil, and may be of the same nature as the cement used for impregnating the cement-impregnated material. Preferably, however, it will be heavier or more concentrated than that cement, such, for example, as might be obtained by using one half or less of the solvent contained in the cement used for impregnation. The coating thus applied to the surfaces to be united serves to fill the surfaces and to lay the nap or surface fibers. This coating is not merely anchored to the surface of the impregnated material but appears to become dissolved into and united with the homogeneous cemented mass of the material and becomes a part thereof. When the coating thus applied to the two surfaces to be united has dried, one of said surfaces is given another coating of adhesive cement, preferably the same as that used for impregnation, and while this coating of cement is still fluid, these two surfaces are applied to each other and are subjected to a suitable even pressure throughout, this pressure being preferably maintained until the cement is set. It is sometimes preferable to apply the solvent used to dissolve the cement, in place of this last coat of adhesive cement, the solvent thus applied apparently sufficing to render the previous coating of cement sufficiently soft and tacky, firmly to unite the layers. Heat applied in conjunction with pressure will conduce to the evaporation of the solvent and the setting of the cement. When the cement is set, the pressure may be removed and the resultant product allowed thoroughly to dry, when the two materials will be found to be permanently cemented to each other. The pressure may be applied in any suitable manner or any suitable means, as for example by subjecting the two superposed layers to direct pressure between heated presser members, such as flat plates, or between presser rolls. But the direct pressure between two flat plates in a stationary press, so constructed that the plates will exert a substantially uniform continued pressure simultaneously on all parts of the material, or a considerable area thereof, for a more or less prolonged interval, or until the cement is set, will in general be found more satisfactory. The pressure as applied will preferably be yielding; it serves to condense and compact the cement-impregnated fibers of the material.

Instead of uniting a cement-impregnated material with one not cement-impregnated, two cement-impregnated materials may be united by following the same mode of procedure above described, excepting that in such case, neither of the surfaces to be united will be roughened before applying thereto the preliminary cement coatings.

In all cases both materials to be united will preferably be warm and dry before the adhesive coat of cement for uniting them is applied, and as already stated the operation will preferably be carried out in a dry atmosphere.

It will be apparent that any number of pieces or sheets of material may be united as described, all of said pieces or sheets being cement-impregnated or one or more being cement-impregnated sheets or pieces, and one or more not. It will also be apparent that the alternative arrangement of the sheets or layers of material may vary as best suited to the purpose for which the resultant product is to be used, the cement-impregnated pieces or sheets and those not impregnated alternating either regularly or irregularly. Thus, where more than two pieces or sheets or layers of material are united, one or more that are not cement-impregnated may be embraced between two or more cement-impregnated ones, or vice versa, or two or more nonimpregnated pieces or sheets or layers may be provided with a single outer impregnated piece, layer or sheet as a wear-receiving member, for example.

It will also be apparent that where more than two layers of pieces of material are united in accordance with my process, they may be united singly, or simultaneously in any numbers desired, it being borne in mind that where an impregnated piece is united to one that is not impregnated, as also where two unimpregnated pieces are united directly, the surface or surfaces of the unimpregnated piece or pieces to which the layer of cement is applied should preferably first be roughened.

The cement layer 3 by which the cement-impregnated pieces or sheets of material are united appears to unite with the cement which permeates said pieces or sheets and forms therewith a homogeneous body. In the same manner the cement that unites a cement-impregnated piece or sheet of material to one that is not so impregnated appears to unite so intimately with the fibers of the non-impregnated piece or sheet as well as with the cement which permeates the cement-impregnated piece or sheet as to form with both of these a homogeneous body. The adhesive layer of cement also acquires the same flexibility and water-repellent characteristics as the impregnated sheet material, so that it becomes one with the material that it unites, with no opportunity or tendency for separation thereat or therefrom, and such layer bends and flexes freely in unison with the pieces or sheets of

1037

material that it unites, so that there appears to be an absence of wear-producing friction between said pieces. The pieces of material and the cement by which they are united and permeated appear to become one homogeneous mass that flexes as a single piece. The adhesive layer between the pieces or sheets renders the resultant product waterproof.

Certain fibrous materials, such as certain kinds of leather, chrome-tanned or other upper leather, for example, which lack resiliency and have a tendency to stretch, become unstretchable and gain resiliency when treated by my process, which is a distinct advantage in the case of many uses to which my product may be applied. It will thus be seen that by my process, greater durability, toughness, compactness may be imparted to leather or similar fibrous materials, than that possessed thereby before treatment. Furthermore, the leather or other fibrous material produced by this process is cement and oil-impregnated and characterized throughout by a fibrous, cellular structure, the size and number of the air cells depending in part on the extent to which the condensing process has been carried out, the process thus rendering the material substantially and permanently water-repellent, while imparting thereto some degree of porosity, so that it possesses an advantage over material of other nonporous, water-repellent or water-proof substances, such for example as rubber. Apparently the fibers become incased with the cement after the material has been immersed, without necessarily wholly filling the interstices between the fibers or wholly expelling the air from within the same.

It will thus be seen that by my process, durability, toughness, compactness and water-repellent qualities may be imparted to cheap or inferior grades of leather so as to make them available for uses and purposes not heretofore possible, and as equal or better substitutes for leather of more expensive grades. Thus, in the case of chrome-tanned leather for example, the normally porous and relatively loose structure of the leather becomes so charged with the cement that the leather has its fibrous structure compacted into a homogeneous, cement-bound, fibrous body. The cement adds to the initial strength of the union of the fibers, but because of the oil still leaves the product flexible. The cement also adds its strength to the strength of the fibers, producing a homogeneous, compact body which can be worked in substantially the same manner as ordinary vegetable-tanned sole leather.

Leather treated by my process will buff and burnish to the same high degree as any other leather and will take quite as perfect a finish, upon its surfaces or edges, when treated by any usual burnishing or finishing process, and will retain that finish.

It will be understood that the terms "sheet" and "sheet material" used in the specification and claims, are used in their broad and comprehensive sense, as including for example any material such as leather, felt, or any textile, woven, or other permeable material in the web or piece.

It has been found that in some cases it is preferable to subject the leather to a degreasing process, in order to remove therefrom any excessive or undesirable oil or grease, or soap, before treating the leather by my process. Any usual or well-known degreasing process may be employed for this purpose, such for example as immersing the leather for the required length of time in a bath of naphtha or benzin or other suitable agent. In the case of textile fabrics the best results are obtained with unsized materials.

While I have herein described one illustrative example of my improved product and the several steps by which one form of my product may be carried out, it is to be understood that my invention is not limited to the exact details specified or any of them, but that these may be varied within wide limits without exceeding the true scope of my invention which is definitely set forth by the claims.

Having described my invention, what I claim as new and desire to secure by Letters Patent is:

1. The method of applying a sheet of leather or other permeable or fibrous material to another sheet of material, which is characterized by drying said sheets; impregnating one throughout with a cement containing a cellulose derivative and a non-oxidizing oil, by immersing it in a heated bath containing said cement in solution; applying to the surfaces of said sheets, by which they are to be united, a coating of cement also containing a cellulose derivative and a non-oxidizing oil; allowing said coatings to dry; applying to one of said surfaces a coating of adhesive cement; superimposing said surfaces while this coating of cement is still tacky; and compacting and cementing said sheets together by the application of pressure.

2. The method of applying a sheet of leather or other permeable or fibrous material to another which is characterized by drying said sheets; impregnating them throughout with a cement comprising a cellulose derivative and a non-oxidizing oil, by immersing them in a heated bath containing said cement in solution; applying to one surface of said sheets a coating of cement also containing a cellulose derivative and a non-oxidizing oil; allowing said coatings to dry; applying to one of said

HOUSE SAFETY FILM

cement-coated surfaces a coat of adhesive cement; superimposing said surfaces while this coating is still tacky; and compacting and cementing said sheets together by the application of pressure.

3. The method of applying a sheet of leather or other permeable or fibrous material to another sheet of material, which is characterized by degreasing the sheet to be applied; drying said sheets; impregnating one throughout with a cement containing a cellulose derivative and a non-oxidizing oil, by immersing it in a heated bath containing said cement in solution; applying to the surfaces of said sheets, by which they are to be united, a coating of cement also containing a cellulose derivative and a non-oxidizing oil; allowing said coatings to dry; applying to one of said surfaces a coating of adhesive cement; superimposing said surfaces while this coating of cement is still tacky; and compacting and cementing said sheets together by the application of pressure.

4. As a new article of manufacture a sheet of leather or other material having applied thereto a water-repellent, wear-resisting member, comprising a sheet or layer of leather or other fibrous or permeable material, impregnating throughout with a cement containing a cellulose derivative and a non-oxidizing oil and cemented to the first-named sheet by an adhesive cement.

5. As a new article of manufacture a sheet of leather or other material having applied thereto a water-repellent, wear-resisting member, comprising a sheet or layer of leather or other permeable or fibrous material, impregnated throughout with a cement containing a cellulose derivative and a non-oxidizing oil, and having its fibrous structure compacted into a cement-bound flexible body and being cemented to said first-named sheet by an adhesive cement.

6. As a new article of manufacture a sheet of leather or other material having applied thereto a water-repellent, wear-resisting member, comprising a sheet or layer of leather or other fibrous or permeable material, impregnated throughout with a cement containing a cellulose derivative and a non-oxidizing oil and cemented to the first-named sheet by an adhesive cement containing similar materials to that used to impregnate said sheet.

In testimony whereof I have signed my name to this specification.

UNITED STATES PATENT OFFICE.

LAWSON B. WILSON, OF WASHINGTON, DISTRICT OF COLUMBIA.

NON-CONDUCTING PLASTIC COMPOSITION OR CEMENT KNOWN AS PLASTIC ENAMEL.

1,389,084. Specification of Letters Patent. Patented Aug. 30, 1921.

No Drawing. Application filed May 7, 1920. Serial No. 379,548.

To all whom it may concern:

Be it known that I, LAWSON B. WILSON, a citizen of the United States, residing at 1203 F street northwest, in the city of Washington, in the District of Columbia, have invented a new and useful Non-Conducting Plastic Composition or Cement Known as Plastic Enamel, of which the following is a specification.

This application is a continuation in part of my application Serial Number 354,232, filed January 20, 192.

The object of my invention is the production of a plastic non-conducting composition or cement known as plastic enamel to be applied to the surfaces of broken objects requiring repair or mending, and for use as an adhesive agent to mend or repair such useful articles as ornaments, dishes, glassware, furniture, wood-work, metals, false-teeth, shoes, rubbers, leaks in gas and water pipes, clothing, shirts, canvas fabrics, auto-tops and seats, build up worn threads, leaks in boats, stiffen, repair and make waterproof, canvas for use on airplanes, etc.

My composition contemplates the use of a preferably gelatinized cellulose ester or other derivative, a solvent therefor, and a phenol. As examples of the cellulose ester or other derivative I find that any ester such as the nitrate or acetate, butyrate etc., or an ether such as the ethyl ether and others as found in Lilenfeld U. S. Patent 1188376 may be used. It is to be understood that cellulose acetate and the cellulose ethers are considered to be equivalents of the nitrocellulose specified in the claims.

As solvents I may use any of the various well known solvents in this art, examples of which are acetone, alcohols, amyl acetate, fusel oil, anilin, nitrobenzol, acetic acid, various essential oils, etc., these solvents being used singly or in combination as phenols.

As phenols, I find phenol, the various cresols, naphthols, etc. to have utility in this connection.

In one exemplification of my composition I find that celluloid, acetone and phenol give a very valuable composition for general purposes. These components may be used in the following proportions:—

Celluloid	4 parts
Acetone	5 parts
Phenol	3 parts

volume.

I find that these proportions are well calculated to give an excellent cementing material for general use. This example is given merely to comply with the statutory requirements, whence it is to be understood that my invention in its broad aspects is not in any way limited thereby.

To secure special properties of advantage under particular circumstances I have found that softening agents, fillers, and pigments may be used.

As softening and plasticizing agents the following are found desirable: camphor, castor oil, naphthalene and its derivatives such as the chlorids, organic esters such as ethyl acetate, inorganic esters such as triphenyl phosphate, molasses, etc.

As fillers, shellac, gums and resins of various kinds, balsam, etc. or inorganic fillers such as heavy spar, calcium carbonate etc. may be used.

For the purpose of coloring the material as desired any dye or pigment, organic or inorganic may be used.

For the purpose of fixing leaks in boats, and holes in shoes or filling up depressions, etc., the composition comprising nitrocellulose, a phenol and a solvent, is poured into a bottle containing pellets of cotton of the size ranging from a one cent piece to a twenty-five cent piece. When this is done the cotton thereby becomes completely saturated with the plastic enamel and may be applied to repair a leaky boat by placing the saturated cotton tightly between the cracks and permitting it to set until hard. In order to make it more secure and permanent it is advisable to pour plastic enamel over the cotton. Good results are obtained by applying small quantities at a time, applying subsequent coats or layers after the first coat has hardened. The same method is pursued in fixing holes in shoes.

This composition of ingredients containing the aforementioned chemicals may be made in different colors by adding pigments such as aluminum, gold, carmine, lampblack, oxid of zinc, etc. By adding pigments, the viscosity of the composition is increased.

My composition is light when set; is a very efficient non-conductor of heat and cold; is impervious to water, hot or cold; adheres to any dry surface, and as a whole possesses to a high degree properties which makes a useful cement for use in households, machine shops, dental offices, and for other use-

Page Tightly Bound

1040

ful commercial purposes. My composition is useful for the making of bridge work, plates, partial plates, plumpers, tightening old sets of teeth, mending cracked plates, and adding teeth to broken sets.

Attempts have been made to produce cementing compositions previously, but they have all fallen short of the admirable materials produced by me because of one of two reasons: first, because they do not use phenols, or second, because they have failed to use a gelatinized cellulose derivative. The first compositions, of course, fall short of that used by the applicant. The second appears to have failed because there was no realization of the valuable properties of a gelatinized cellulose derivative. In such form, the gelatinized cellulose is much more susceptible to chemical action, and I believe that in this form, when treated with such materials as acetone and phenol, there is a relatively slow tendency to form condensation products. However, whatever the action may be, I find that by my composition I have been able to secure unique properties not before known in this art. Obviously by varying the proportions of the materials the viscosity of the mixture can be controlled.

I claim:

1. A nitrocellulose composition containing celluloid, four parts; acetone, five parts; phenol, three parts, all by volume.

2. A cementing composition comprising the following:—

Nitrocellulose	4 parts
Acetone	5 parts
Phenol	3 parts

all by volume.

L. B. WILSON.

Reissued Nov. 29, 1927. Re. 16,803

UNITED STATES PATENT OFFICE.

EDMUND M. FLAHERTY, OF PARLIN, NEW JERSEY, ASSIGNOR TO E. I. DU PONT DE NEMOURS & COMPANY, OF WILMINGTON, DELAWARE, A CORPORATION OF DELAWARE.

LOW-VISCOSITY LACQUER AND FILM PRODUCED THEREFROM.

No Drawing. Original No. 1,629,999, dated May 24, 1927, Serial No. 471,931, filed May 23, 1921. Application for reissue filed September 19, 1927. Serial No. 220,623.

This invention relates to low viscosity lacquers and films produced therefrom, and more particularly to lacquers made from cellulose esters or nitrates having a greatly reduced viscosity and containing resins or oils that will impart such qualities to the lacquers that, upon drying in two or three coats, films will result that will be hard, durable, tough, and adhesive, together with other valuable properties.

It is an ultimate object of my invention to provide a film whose principal constituent will be a cellulose nitrate, which film will possess the characteristics of hardness, durability, toughness, transparency, freedom from acidity, lustre, and capability of adhesion to a surface to be coated; and which will at the same time be built up of only two or three layers or coats. A further object in this connection is to utilize cellulose nitrates which have been greatly reduced in viscosity, but which have not been reduced to the point that the nitrogen content is degraded and the transparency and solubility of the cellulose nitrate impaired. A further object is to prepare lacquer and enamel compositions that will, upon drying, provide a film as aforesaid possessing a continuous unbroken appearance. Further objects of the invention will appear as the following description proceeds.

According to my invention pyroxylin solutions, and particularly lacquers, having an abnormally high nitrocellulose content in conjunction with a suitably low viscosity are produced by subjecting pyroxylin mixtures of the character hereinafter described, for a prolonged period, say from one to three weeks, preferably at ordinary room temperature, to the action of a metal salt of a weak acid, for example an alkali-forming metal acetate. The discovery of the action of salts of this kind on the viscosity of pyroxylin solutions is described in the patent of Earle C. Pitman No. 1,636,319, and the application of this discovery to the reduction of viscosity of pyroxylin solutions is claimed broadly therein. By a particular application of this discovery to high percentage pyroxylin solutions, I have found it practicable to produce solutions, such as lacquers and colored enamels, of such a high pyroxylin content that they will deposit in two coats a film as heavy and satisfactory as the ordinary solutions do in four coats or more.

My invention may be illustrated in detail by the following examples:

I. I first make up a solution of from 25 to 30% pyroxylin in suitable solvents. A typical pyroxylin base solution for this purpose may be made according to the following formula:

	Parts.
Amyl acetate	11
Amyl alcohol	5
Acetone	35
Toluene	14
Denatured alcohol	5
Pyroxylin	28

To this mixture is added .56 part by weight of crystalline sodium acetate preferably dissolved in methyl alcohol. The amount of sodium acetate added may with advantage be from about 0.1 to 3% of the weight of pyroxylin in the solution; I preferably use 2%.

The resulting mixture is allowed to stand several weeks in a warm room and at the end of this time the viscosity is found to have dropped to a very low point, too low even for most purposes. I then add a slight amount of heavy viscosity pyroxylin which brings the solution viscosity up to a suitable working point where it stays indefinitely, there being no further action of the sodium acetate. To the solution containing a very high percentage of pyroxylin I now add suitable gums, oils and colors to impart extra adhesiveness, flexibility and shade as desired. Thus, after the viscosity has been reduced to a minimum and brought back to a suitable point, a lacquer can then be prepared by making a mixture containing 56% of this base solution, 9% of castor oil and 35% of a 50% gum solution in suitable solvents. This gum may be dammar, shellac or any of the other common gums used in lacquers. Dammar may first be dissolved in a mixture of toluene and benzene. Shellac may be used in the form of its solution in alcohol. Instead of castor oil, various other

vegetable oils, such as blown cotton-seed oil, may be added to impart flexibility to the coating.

In a similar way a colored enamel can be made from the original base solution by the addition of pigments ground in oil.

II. Instead of preparing the base solution of high percentage pyroxylin and correct viscosity in two steps, I may prepare it in one step by mixing all the pyroxylin with the solvent at the start, adding about 2%, based on the weight of pyroxylin, of sodium acetate, and allowing to stand, until the reduction in viscosity has progressed to the desired extent. The amount of pyroxylin added in this alternative procedure may be such, for example, that the resulting mixture will contain from about 30 to 40% of pyroxylin. After adding the sodium acetate the mixture is preferably allowed to stand at room temperature for about three weeks. Where less than 2% of sodium acetate is used, a longer time will be required.

By following the procedure set forth in the above examples a 25 to 40% pyroxylin solution may be obtained having a viscosity below 25,000 centipoises, as determined in the Stormer viscosimeter, at 28° C., 25,000 centipoises being practically the upper limit for any commercial solution which is to be used for coating without thinning. A centipoise is a c. g. s. unit of viscosity, water being about 1 centipoise at 20.2° C. Such solutions will, as a rule, be considerably diluted with solvents before being used in spraying or brushing surfaces to be coated.

In place of sodium acetate various other substances may be used as viscosity-reducers, either singly or two or more together. The alkali-metal formates and acetates are especially useful, and the alkaline earth metal salts, as well as the cadmium, cobalt, and zinc salts, of these same acids have a marked effect on the viscosity of pyroxylin solutions. In general, of the salts of organic acids, the water-soluble salts of the lower monobasic aliphatic acids appear to act as the best viscosity-reducers. Salts of some inorganic acids also exhibit this property, as for example the alkali-metal borates, iodides, sulphocyanates, etc.

The pyroxylin solutions coming within the purview of my invention are, of course, not confined to the particular solvent mixture given in the above examples. Thus instead of amyl acetate and amyl alcohol, I may use butyl acetate and butyl alcohol, respectively; and in place of toluene, the other benzenoid hydrocarbons such as benzene and xylene may be used. In fact any of the well-known solvent mixtures may be substituted for the one mentioned in the above examples without departing from my invention, said mixtures usually comprising a diluent such as benzene.

The maximum pyroxylin content of pyroxylin solutions which have heretofore been of practical use for coating purposes, has been about 15%, whereas the solutions made according to my invention will contain as a rule, if undiluted, more than 20% of pyroxylin, and in many cases between 25 and 40%. The above figures of 15% and 20% have particular reference to pyroxylin which has been dissolved in a mixture of solvents instead of in a single solvent. Such solutions may, of course, be diluted with solvents for spraying or brushing purposes.

The new lacquer is differentiated from cellulose nitrate lacquers heretofore known in that it contains at least 25% and sometimes from 50 to 150% more cellulose nitrate at a given viscosity than does a corresponding lacquer of the same viscosity and having the maximum content of cellulose nitrate which has not been subject to the above subscribed treatment with sodium acetate or a similarly functioning agent.

My new lacquer may be differentiated from prior lacquers by stating that the viscosity-characteristic of the nitrocellulose in the new lacquer is substantially lower than that of the nitro-cellulose contained in the lacquers heretofore known. This distinctive feature of the new lacquer makes it possible to identify the same irrespective of the extent to which the new lacquer is modified or thinned by the addition of gums, volatile solvents or diluents, etc. The above-mentioned viscosity-characteristic of the pyroxylin component of the new lacquer may advantageously be defined in terms of the viscosity that it imparts to some convenient solution taken as a standard when measured by a standard method. I have found it desirable to express this inherent viscosity-characteristic in terms of the viscosity possessed by a 16 ounce ethyl acetate solution of the reduced viscosity nitrocellulose when measured by the Stormer viscometer, at 28° C. Thus, a 25% pyroxlin solution having the solvent composition set forth in Example I above, and having a viscosity of 25,000 centipoises, as determined in the Stormer viscometer at 28° C., using a 500 g. weight, contains nitrocellulose which, when dissolved in toto in pure ethyl acetate (over 99.5%) to form a 16 oz. solution, imparts to said ethyl acetate solution a viscosity of about 1200 centipoises when tested in said viscometer at 28° C. In the preferred embodiment the lacquers and base solutions constituting my invention are consequently clearly differentiated from the lacquers of the prior art by containing, for their pyroxylin content, nitrocellulose whose inherent viscosity-characteristic is such that when said nitro cellulose is dissolved in pure ethyl acetate to form a 16 oz. solution, said solution possesses a viscosity of less than 1200 centipoises when

tested in the Stormer viscometer at 28° C. (using a 500 g. weight), and generally the said lacquers and solutions are distinguished over the prior art by containing a nitrocellulose whose inherent viscosity characteristic is such that at above 20% concentration in a mixed solvent of the character described in Example I, it will provide a solution below 25,000 centipoises in viscosity.

I use the expression (1) "16 oz. solution" and (2) "16 oz. ethyl acetate solution" in the sense customary in the art of pyroxylin solutions, that is, to mean (1) 16 ounces of nitro-cellulose dissolved in 1 gallon of solvent, and (2) 16 ounces of nitrocellulose dissolved in 1 gallon of ethyl acetate, respectively, at ordinary room temperature (22° C.).

When the new solutions hereinbefore described are used to coat various kinds of surfaces, particularly rigid metal or wood surfaces, to provide films thereon, either by spraying, brushing or dipping, the resulting films will be hard, durable, lustrous, transparent, tough, and continuous, and will adhere to the underlying surface. These films may be made of proper and sufficient thickness by the application of two or three coats, whereas in former practice where high viscosity nitrocellulose was used, a much larger number of coats had to be applied to obtain a film of sufficient thickness. My new films are particularly characterized by their toughness, i. e., the absence of any brittleness, this result being achieved by the admixture of the ingredients of the lacquer or enamel, with nitrocellulose, whose viscosity has been reduced by means of sodium acetate, or its equivalent in function, whereby the nitrogen content is not seriously reduced and correspondingly the resulting solubility of the nitrocellulose and toughness of the film remains substantially unimpaired. The use of the sodium acetate, which has an alkaline reaction, and the absence of acidic products in the low viscosity solutions or lacquers, permits of the addition of basic pigments without liability of incurring undesirable reactions.

It will, therefore, be apparent that I have provided lacquers and enamels containing a much higher proportion of nitrocellulose for a given viscosity than was hitherto possible, without in any way impairing the aforesaid characteristics of the film to be prepared, while at the same time making possible the easy application of these lacquers and enamels upon surfaces to be coated. As a result, films of the aforesaid excellent characteristics may be prepared, by the application of only two or three coats of my new lacquers or enamels, whereas in the old art it was necessary to put on many more coats in order to build up a film of proper and suitable thickness, this latter difficulty having been due to the necessary low nitrocellulose content of the prior art solutions at a working viscosity.

As many apparently widely different embodiments of this invention may be made without departing from the spirit thereof, it is to be understood that I do not limit myself to the foregoing examples, except as indicated in the appended claims.

I claim:

1. A pyroxylin coating composition comprising nitrocellulose, a softener therefor, and a volatile nitrocellulose-solvent, the viscosity-characteristic of the nitrocellulose, expressed as the viscosity of a 16 oz. solution thereof in C. P. ethyl acetate, being less than 1200 centipoises when measured by the Stormer viscometer at 28° C.

2. A pyroxylin coating composition comprising nitrocellulose, a softener therefor, a gum, and a volatile solvent for the three first mentioned ingredients, said nitrocellulose, when 16 ounces thereof is dissolved in 1 gallon of pure ethyl acetate, yielding a 16 oz. solution whose viscosity is less than 1200 centipoises when measured by the Stormer viscometer at 28° C.

3. A pyroxylin coating composition comprising nitrocellulose, a volatile nitrocellulose-solvent, a softener for the nitro-cellulose, a gum, and a pigment, said nitrocellulose, when 16 ounces thereof is dissolved in 1 gallon of pure ethyl acetate, yielding a 16 oz. solution whose viscosity is less than 1200 centipoises when measured by the Stormer viscometer at 28° C.

4. A coating composition comprising cellulose nitrate having an inherent viscosity characteristic such that at 25% concentration in a mixed solvent of the composition here inbefore described it will provide a solution below 25000 centipoises in viscosity, and comprising also a resin and a solvent.

5. A composition comprising cellulose nitrate having a viscosity, as determined upon a 16 oz. solution of ethyl acetate with the Stormer viscometer at 28° C., of less than 1200 centipoises, and comprising also a resin and a solvent.

6. A coating composition comprising cellulose nitrate having an inherent viscosity characteristic such that at 25% concentration in a mixed solvent of the composition hereinbefore described it will provide a solution below 25000 centipoises in viscosity, and comprising also a resin, an oil, and a solvent.

7. A composition comprising cellulose nitrate having a viscosity, as determined upon a 16 oz. solution of ethyl acetate with the Stormer viscometer at 28° C., of less than 1200 centipoises, and comprising also a resin, and solvents to bring the viscosity of the composition below 25000 centipoises.

8. An article covered with a hard, dura-

ble, tough, and adhesive film formed from a composition comprising a cellulose nitrate having an inherent viscosity characteristic such that at 25% concentration in a mixed solvent of the composition hereinbefore described it will provide a solution below 25000 centipoises in viscosity, and comprising also a resin.

9. A composition comprising cellulose nitrate having a viscosity, as determined upon a 16 oz. solution of ethyl acetate with the Stormer viscometer at 28° C., of less than 1200 centipoises, and comprising also a solvent and a resin, said composition being adapted upon drying of not over three coats to form a hard, durable, tough, and adhesive film.

10. A composition comprising cellulose nitrate having a viscosity, as determined upon a 16 oz. solution of ethyl acetate with the Stormer viscometer at 28° C., of less than 1200 centipoises, and comprising also a solvent, a resin, and a basic pigment, said composition being non-acidic whereby no reaction occurs with said pigment, and said composition being adapted upon drying of not over three coats, to form a hard, durable, tough, and adhesive film.

11. An article covered with a hard, durable, tough, and adhesive film formed from a composition comprising a cellulose nitrate having a viscosity, as determined upon a 16 oz. solution of ethyl acetate with the Stormer viscometer at 28° C., of less than 1200 centipoises, and comprising also a resin and a solvent.

12. An article covered with a hard, durable, tough, and adhesive film formed from a composition comprising a cellulose nitrate having a viscosity, as determined upon a 16 oz. solution of ethyl acetate with the Stormer viscometer at 28° C., of less than 1200 centipoises, and comprising also a resin, an oil, and a solvent.

13. A composition comprising cellulose nitrate having an inherent viscosity characteristic such that at above 20% concentration in mixed solvent of the composition hereinbefore described it will provide a solution below 25000 centipoises in viscosity, and comprising also a resin and a solvent.

14. A composition comprising cellulose nitrate having an inherent viscosity characteristic such that at above 20% concentration in mixed solvent of the composition hereinbefore described it will provide a solution below 25000 centipoises in viscosity and comprising also a resin and solvents to bring the viscosity of the total composition below 25000 centipoises.

15. An article covered with a hard, durable, tough, non-shrinking and adhesive film formed from a composition comprising a cellulose nitrate having a viscosity characteristic such that at above 20% concentration in mixed solvent of the composition hereinbefore described it will provide a solution below 25000 centipoises in viscosity, and comprising also a resin.

16. An article coated with a hard, durable, tough, and adhesive film formed from a composition containing a resin, a softener, and a cellulose nitrate having a low viscosity characteristic such that at above 20% concentration in mixed solvent of the composition hereinfore described it is capable of producing a solution below 25000 centipoises in viscosity.

17. A rigid article coated with a hard, durable, tough, and adhesive colored enamel formed from a composition containing a resin and a cellulose nitrate having an inherent viscosity characteristic such that at 25% concentration in a mixed solvent of the composition described in Example I the latter will have a viscosity below 25000 centipoises.

In testimony whereof, I affix my signature.

EDMUND M. FLAHERTY.

DISCLAIMER

Re. No. 16,803.—*Edmund M. Flaherty*, Parlin, N. J. LOW-VISCOSITY LACQUER AND FILM PRODUCED THEREFROM. Patent dated November 29, 1927. Disclaimer filed May 26, 1932, by the assignee, *E. I. du Pont de Nemours & Company*.

Hereby enters this disclaimer to that part of said specification and claims which is in the following words: to wit: "and generally the said lacquers and solutions are distinguished over the prior art by containing a nitrocellulose whose inherent viscosity characteristic is such that at above 20% concentration in a mixed solvent of the character described in Example I, it will provide a solution below 25,000 centipoises in viscosity". (P. 3, 11.2–9.)

"13. A composition comprising cellulose nitrate having an inherent viscosity characteristic such that at above 20% concentration in mixed solvent of the composition hereinbefore described it will provide a solution below 25,000 centipoises in viscosity, and comprising also a resin and a solvent.

"14. A composition comprising cellulose nitrate having an inherent viscosity characteristic such that at above 20% concentration in mixed solvent of the composition hereinbefore described it will provide a solution below 25,000 centipoises in viscosity and comprising also a resin and solvent to bring the viscosity of the total composition below 25,000 centipoises.

"15. An article covered with a hard, durable, tough, nonshrinking, and adhesive film formed from a composition comprising a cellulose nitrate having a viscosity characteristic such that at above 20% concentration in mixed solvent of the composition hereinbefore described it will provide a solution below 25,000 centipoises in viscosity, and comprising also a resin.

"16. Patented Sept. 15, 1925. 1,554,033

UNITED STATES PATENT OFFICE.

EBENEZER EMMET REID, OF BALTIMORE, MARYLAND, ASSIGNOR TO E. I. DU PONT DE NEMOURS & COMPANY, OF WILMINGTON, DELAWARE, A CORPORATION OF DELAWARE.

CELLULOSIC COMPOSITION.

No Drawing. Application filed February 4, 1921. Serial No. 442,474.

To all whom it may concern:

Be it known that I, EBENEZER EMMET REID, a citizen of the United States, and a resident of Baltimore, in the State of Maryland, have invented certain new and useful Cellulosic Compositions, of which the following is a specification.

This invention relates to cellulosic compositions containing as an essential constituent a neutral butyl phthalate, and has reference more particularly to cellulose nitrate plastics containing dibutyl phthalate.

In the practical application of dissolved cellulose and soluble cellulose compounds, including cellulose esters, to the various arts and manufactures, such as the production of films, varnishes, filaments, plastic masses, etc., it is customary to blend or mix or otherwise add to the cellulose ester or to its solution, certain non-cellulosic materials commonly termed softeners, camphor substitutes or the like, such additions being made for the purpose of imparting to the cellulose or its compounds some desired properties, such as non-inflammability, plasticity under heat, flexibility, etc. These softeners, camphor substitutes and the like, which I shall hereinafter for convenience designate as "modifiers," function in many different ways in cellulosic combinations; and the properties which they impart to the product depend upon and are determined by both the physical and the chemical properties of the particular modifier used. For example, if a modifier is non-inflammable, it will impart this property to the cellulose to a degree which is of course dependent upon the character of the modifier and the proportion added; if the modifier is relatively non-volatile its effect will be more permanent than that of a more volatile modifier; if the modifier is a solvent under suitable conditions for the cellulose material, it will as a rule impart greater flexibility than if it is a non-solvent; and particularly, modifiers which are liquid at normal temperatures will, other things being equal, impart greater flexibility than those which are solid at normal temperatures.

I have found that the neutral esters of phthalic acid (that is, ortho-phthalic acid) in which at least one of the alcohol radicals is a butyl group are more suitable as modifiers than most substances which have heretofore been proposed for this purpose.

By the expression "neutral butyl phthalates" I include not only a dibutyl phthalate but also the mixed esters such as methyl butyl, ethyl butyl, and propyl butyl, phthalates. I prefer to use esters of the kind above indicated in which the butyl radical is that of normal butyl alcohol rather than of isobutyl alcohol, and specifically, di (normal) butyl phthalate.

The procedure which may be followed to produce the above-mentioned butyl phthalic acid esters may be illustrated by the following examples:—

From phthalic anhydride.

Three parts by weight of phthalic anhydride are added to 3½ parts of normal butyl alcohol (B. P. 115–117° C.) and the mixture heated to 117° C. for eight hours. This completes the first reaction with the formation of mono-butyl phthalate which remains dissolved in the excess alcohol. Three per cent by weight of dry hydrogen chloride is dissolved in the mixture, which is heated to 117° for eight hours. The second reaction is accompanied by the separation of a layer of water. This is separated and the heating continued for an additional eight hours. The resulting liquid product is first washed with water to remove the hydrochloric acid; then with strong sodium carbonate to remove the mono-butyl phthalate and any free phthalic acid; and finally with water several times until neutral. The dibutyl phthalate is purified from alcohol and dried by passing a current of air through the liquid heated to 160° C. The product is a liquid, odorless, slightly yellow in color and may be obtained water white by distilling under diminished pressure. The yield is 83.6% of the theoretical. Boiling point under 29 mm. pressure is 210° C.

From phthalic acid.

The use of phthalic acid requires a catalyst for both stages of the reaction. One part by weight of phthalic acid is mixed with 2.5 parts of normal butyl alcohol (B. P. 115–117° C.). Three per cent by weight of dry hydrogen chloride is dissolved in the mixture, which is heated to 117° for twenty-four hours. The water which forms as a lower layer is drawn off from time to time and more hydrogen chloride added toward the latter part of the

Page Tightly Bound

heating. The product is washed and purified in the same manner as described above. The yield from phthalic acid is 79.2% of the theoretical.

Mono-butyl phthalate.

Mono-butyl phthalate is obtained as a by-product from either of the above methods and is recovered by acidifying the sodium carbonate wash waters. This can be utilized in the preparation of di-butyl phthalate or for the purpose of making mixed esters. It is a white crystalline solid melting at 73–74° C., soluble in all the usual organic solvents and in alkali. Recrystallized from acetone or alcohol it is obtained in large rhombic plates.

The cellulosic compositions, and particularly the cellulose esters such as the acetate and nitrate, containing a butyl phthalic acid ester as a modifier have a practical application in many arts as, for example, in artificial leather, celluloid, lacquers, photographic film, etc.

In preparing the new cellulosic compositions, the butyl phthalic acid ester may be used in various proportions depending upon the result sought, as will be readily understood. As one illustrative example of the practice of the invention, I may incorporate thirty parts by weight of dibutyl phthalate with 100 parts of cellulose nitrate.

For producing flexible films, a suitable solution may be prepared by dissolving cellulose nitrate and dibutyl phthalate in the ordinary solvents such as ethyl acetate, benzene, methyl or ethyl alcohol and acetone, etc. Pigments and colors may be incorporated, and also, in the production of plastics, a suitable amount of a stabilizer, such as urea.

The properties of di (normal) butyl phthalate (and in general of the neutral butyl phthalates above described) which make it especially valuable in pyroxylin compositions may be listed as follows:

1. It is a solvent for pyroxylin.
2. It is a liquid at ordinary temperatures and does not crystallize when cooled very much below room temperature, for example to –17° C.
3. It has a very low volatility at ordinary temperatures.
4. It undergoes practically no change on storage either in bulk or in a pyroxylin film.
5. It is colorless.

The neutral butyl phthalates are new substances and are claimed as such in my co-pending application Ser. No. 428,018 filed December 3, 1920.

I claim:—

1. A composition comprising essentially a cellulose ester and, as a modifier therefor, a neutral butyl phthalate.
2. A composition comprising essentially a cellulose ester and, as a modifier therefor, di-butyl phthalate.
3. A composition containing a cellulose ester and a neutral (normal) butyl phthalate.
4. A composition containing a cellulose ester and a di (normal) butyl phthalate.
5. A composition containing cellulose nitrate and a neutral butyl phthalate.
6. A composition containing cellulose nitrate and a neutral normal-butyl phthalate.
7. A composition containing cellulose nitrate and di (normal) butyl phthalate.
8. A film comprising a cellulose ester in admixture with a neutral butyl phthalate.
9. A film comprising a cellulose ester in admixture with di (normal) butyl phthalate.

In testimony whereof I affix my signature.

EBENEZER EMMET REID.

EUGENE C. SMITH AND VICTOR E. SMITH, OF PROVIDENCE, RHODE ISLAND.

SEALING MATERIAL FOR BOTTLES AND THE LIKE.

983,319. Specification of Letters Patent. Patented Feb. 7, 1911.

Application filed September 27, 1909. Serial No. 519,652.

To all whom it may concern:

Be it known that we, EUGENE C. SMITH and VICTOR E. SMITH, both citizens of the United States, and residents of the city and county of Providence, in the State of Rhode Island, have invented new and useful Improvements in Sealing Materials for Bottles and the Like; and in order that those skilled in the art may understand and practice our invention we give the following specification.

We have illustrated our invention in the accompanying drawings, of which—

Figure 1 is a cross section view of the sealing material, and Fig. 2 is a similar view of a metallic cap such as is used for sealing bottles having a sealing disk constructed in accordance with our invention inserted therein.

Our invention relates to sealing material for hermetically closing bottles and similar vessels to preserve their contents, and it has for its object to provide a sealing material for the purposes stated which shall possess advantages over the materials at present generally known and commonly used.

Our invention is more particularly intended to provide an improved sealing material for use in connection with metallic caps which are crimped upon the necks of bottles, which sealing material shall be easy and inexpensive to manufacture and which shall form a perfect gas and air tight seal to prevent the contents of the bottles from deterioration, and which shall be unaffected by the conditions involved in capping, bottling and sterilization, and also unaffected by the liquids or contents inclosed in the bottles, and at the same time impart no flavor or objectionable influence to the same.

Cork has long been regarded as the most satisfactory and efficient sealing material for the purposes stated, but owing to the growing scarcity and increasing cost of the same various expedients have been proposed from time to time to meet this condition. The wide use of the metallic or crown cap while reducing the amount of cork required to form a seal compels the selection of the finest grade of cork, freest from pores, in order to produce a gas or air tight seal. This condition not only involves the expense of the best grade material, but also the expense involved in the process of selection and gives rise to considerable waste. In order to insure gas tight seals of cork and similar material, it was found necessary to back the cork disk or lining of the cap with such material as paraffin paper or the like; but this while adding to the expense did not remedy but only mitigated the difficulty. Various materials other than cork have been proposed but these, so far as we are aware, are generally either too expensive in their production or are inferior to cork as a seal, or deteriorate with age, or do not withstand the conditions occurring in capping, bottling or sterilization, or impart a flavor or odor to the contents of the bottles, or are acted upon by such contents. When the enormous quantity of bottle seals required for use are considered, the item of expense or cost of their production becomes a leading feature for consideration, and when it is further considered that in a large proportion all the materials to be bottled consist of aerated or carbonated liquids, or liquids containing or generating gas under pressure, it will be apparent that a successful sealing material must be low in cost of production and must at the same time form such a perfect seal with the neck of the bottle that no air may enter or gas escape.

Our invention which from careful tests has been found to satisfy and fulfil the above stated conditions and requirements is carried out as follows. We take a sheet of relatively soft compressible felt or fibrous material of about one twelfth of an inch more or less in thickness. For this material we have found satisfactory a specially made compressible felt paper closely resembling blotting paper but preferably softer. This material is represented in Fig. 1 of the drawings on an exaggerated scale as to thickness by the numeral 1. On one side of this compressible fibrous material 1 we secure a sheet of thin but tough and strong fibrous paper. For this thin sheet material, we have found a good Manila paper to give satisfactory results. This thin sheet material is represented in the drawings by the numeral 3. The thin tough sheet 3 is attached to the soft compressible sheet 1 by means of an elastic glue composition, indicated at 2, of such character as will not become hard or brittle upon drying or setting. For this purpose we employ an elastic glue composition made up of glue, glycerin and saccharine material such as sugar or molasses, in about the proportions respectively as they are used in the well

Page Tightly Bound

known printers' roller composition. This elastic glue composition 2 is spread upon the thin sheet material 3, and a number of such sheets coated with said composition may be prepared, to be used as may be necessary. When these sheets are used the glue composition is softened or melted by placing the sheets upon a steam table or hot plate or by heating them in any convenient manner. When the glue has been softened or melted in this manner the thin sheets are applied to the compressible fibrous sheets 1, pressure being applied by means of rollers or otherwise, and the two sheets are united and are then laid aside to dry and set. The outer face of the thin sheet is then coated with a layer of cellulosic varnish, as indicated by numeral 4. For this material we prefer to use a flexible pyroxylin or collodion varnish or the so called celluloid varnish. This coating is applied to such thickness that the same will, when fully dried, be of about two thousandths of an inch thick. When this cellulosic coating is dried, which will take but a few minutes, sealing disks of a size to snugly fit the caps may be stamped therefrom, and are ready for insertion in the caps. It will be understood that the cellulosic varnish coating 4 will in use come in contact with the edges of the mouths of the bottles.

The material produced as above described constitutes a very perfect sealing material for liquids and beverages of all kinds such as are usually bottled and sealed. It forms a practically perfect seal when applied in the usual manner or with the sealing and capping machines usually employed by bottlers, being air and gas tight and successfully sealing the gas contained or generated in gaseous or aerated liquids against escape. The cellulosic coating being flexible and stretchable and impervious to gases, forms a gas and air tight seal and when the seal is applied by the usual bottling apparatus, it forms a perfect gas and air tight seal, the compressible fibrous backing sheet yielding to the pressure of the mouth of the bottle and the cellulose coating being flexible and stretchable, makes close contact about the lips or edges of the mouth of the bottle preventing access of air to, or escape of gases from the contents of the bottle. The cellulose coating is also unaffected by contact with the contents of any liquids or beverages which are customarily put up in bottles for sale and imparts no odor or flavor to such liquids or beverages. The materials employed in the manufacture of our sealing material are such that the same may be produced at a cost below that of cork or of any satisfactory substitute sealing material with which we are acquainted. Our sealing material also withstands a degree of heat as high as 250° F. or a heat which is considerably higher than any degree of heat used in the sterilizing or pasteurizing processes employed in bottling.

We are aware that pyroxylin, celluloid or the like, varnish is, *per se*, old as a varnish or surfacing material, but we are the first, so far as we are aware, to discover that the same possesses properties and characteristics in relation to the sealing or capping of bottles and the like, particularly in combination with other features of our invention, whereby important and useful advantages are obtained, and a sealing material produced which successfully meets the requirements and conditions of a bottle seal, and we therefore claim the employment of the same in this connection broadly.

What we claim is:

1. A sealing material of the character described, comprising a body portion of compressible fibrous material and a layer or facing thereon of flexible cellulosic varnish to contact with the mouth of the vessel to be sealed.

2. A sealing material of the character described, comprising a backing of compressible fibrous material, a relatively thin paper sheet united thereto and a coating or layer of flexible cellulosic varnish on said thin paper sheet.

3. A sealing material of the character described, comprising a body portion of compressible fibrous material and a layer or facing of flexible collodion varnish to contact with the mouth of the bottle to be sealed.

4. A sealing material of the character described, comprising a backing of compressible fibrous material, a relatively thin paper sheet united thereto and a coating or layer of flexible collodion varnish on said thin paper sheet.

5. A sealing material of the character described, comprising a backing of compressible fibrous material, a relatively thin paper sheet united thereto by a flexible glue composition, and a coating or layer of flexible collodion varnish on said thin paper sheet.

6. The combination with a metallic sealing cap of a sealing disk therein, said disk comprising a body portion of compressible fibrous material having an outer layer or facing of flexible collodion varnish.

7. The combination with a metallic sealing cap of a sealing disk therein, said disk comprising a body portion of compressible fibrous material, a facing of thin paper united thereto and an outer coating of flexible collodion varnish on said paper.

UNITED STATES PATENT OFFICE

ALBIN H. WARTH, OF BALTIMORE, MARYLAND, ASSIGNOR TO CROWN CORK & SEAL COMPANY, INC., OF BALTIMORE, MARYLAND, A CORPORATION OF NEW YORK

CLOSURE AND INTERIOR FACING THEREFOR

Application filed December 22, 1930. Serial No. 504,409.

The present invention relates to closures, and more particularly to an improved interior facing for closures and method of producing the same.

Although the invention is applicable to closures of any type in which an interior facing may be usable, from a more specific aspect it is particularly applicable to closures of the crown type and which have a center spot for facing and protecting from container contents the liner of cushion material.

For center spots, it has been customary to employ various materials, such as aluminum foil, tin foil, and paper or other fibrous material having a gas and liquid impervious coating.

The present invention has as an object the provision of an improved facing of the metal foil type. In crown caps, metal foil has been used as a spot in caps intended for the sealing of mineral waters, soda waters, beers, and other liquids. These metal spots are commonly made of tin foil, or aluminum foil. There are some liquids, however, with which it has not heretofore been practicable to utilize a foil facing, and the present invention seeks to provide an improved facing of metal foil which will effectively resist the action of liquids for which metal foil has been unsuitable as a cap spot or facing.

Moreover, the invention seeks to provide an improved facing which will permit the use of aluminum foil for the capping of liquids with which it has heretofore been practicable to use only tin foil. For certain highly carbonated alkaline and saline waters, the relatively more expensive tin foil spotted or faced caps have been used to the exclusion of other metal foil and of paper. Since closures, particularly those of the crown type, are sold for only a few cents a gross, a saving of only a fraction of a cent per crown per dozen crowns is of considerable importance.

Moreover, for certain liquids, for example those requiring high temperatures for sterilization, metal foil facings are unsatisfactory, particularly if the liquids contain acids such as citric acid, lactic acid, and acetic acid. When subjected to such acids, the foil becomes tarnished, corroded, or even dissolved if the acid is very strong. Aluminum foil tends to corrode or tarnish in the presence of fruit acids, and to be eaten away by minute amounts of alkalies, alkaline earths, and mineral salts, which are present in waters.

The present invention seeks to provide a facing of the foil type, and particularly a facing of aluminum foil, which will be resistant to such alkalies, alkaline earths, and mineral salts, and which will not be easily eaten away by fruit acids, such as are present in ginger ale and other acidulated beverages.

Another object of the invention is to provide a foil facing of distinctive appearance which will facilitate the distinguishing of aluminum and tin foil facings and of the materials when in strip form, and which will also permit the use of foil without the usual foil appearance, thereby enabling this material to be used in instances and where the employment of foil might be objectionable, for example because of the widely recognized non-resistant characteristics of foil. It will be understood that it is frequently very difficult to distinguish aluminum foil and tin foil from one another. Moreover, there is widespread objection to closures with foil facings because of the weakness of this material in the presence of acids and alkalies.

The invention will be described in connection with the manufacture of a closure of the crown type and provided with a center spot. Spot crowns are well known in the art, and are illustrated for example in the patent to McManus, No. 1,339,066, granted May 4, 1920. Although described as applied to crown caps, it will be understood that the invention is applicable to caps of other types, such as screw or lug caps, and is not limited to a cap-facing of smaller diameter than the cap.

Referring to the accompanying drawing, wherein there is shown one embodiment of the invention,

Figure 1 is a perspective view showing the laminated material used in the preferred method of manufacturing the cap.

Figure 2 is a plan view partly broken away

showing the disc formed from the material illustrated in Figure 1.

Figure 3 is an interior face view of a completed cap.

Figure 4 is a cross sectional view, and

Figure 5 is a cross sectional view of a modified form of cap.

In order to produce a cap having a facing of the desired character, it is preferred to utilize a laminated material which is made up in sheet or strip form, and from which the facing may be punched and applied to the cap for assembly in the manner illustrated and described in my Patent No. 1,788,260, granted January 6, 1931.

This material comprises an intermediate layer 10 (Fig. 1) of waterproof material, such as tin or aluminum foil. One surface of the material is coated with a layer of suitable adhesive 11. I prefer an adhesive which is waterproof and, to a certain extent, acid resistant, such as gutta percha or a mixture of gutta percha and other gum. Another adhesive which has been found satisfactory is a mixture of damar resin, turpentine rosin, bodied linseed oil, poppy-seed oil, the mixture being thinned with mineral spirits and permitted to dry after application to the foil. This adhesive, as well as one which includes gutta percha, is normally hard or firm at room temperature, and consequently the spot material can be conveniently handled in strip form, in which form it may be stored in rolls adapted to be used in the cap forming machines. Moreover, such an adhesive will become tacky upon the application of heat, and hence will unite the spot material to the cap upon the application of heat and pressure, which may be simultaneously applied, as by the punch which forms the facing discs or spots from the strip material. Since the adhesive is water-resistant and acid resistant it constitutes an additional layer which will protect the cushion material of the cap should the foil material become weakened or perforated by the alkalies, acids or alcohol in the capped liquids.

Still another adhesive which may be used is one one containing as its principal constituent pitch, preferably fused pitch of a moderately hard or hard consistency having a melting point of more than 140° F. By pitch is meant the residue from the distillate of coal-tar, shale oil, petroleum, or vegetable oil. For coating purposes the pitch may be dissolved in suitable solvents such as benzol or toluol, the solvent being evaporated off in the drying of the coating. The pitch may be also combined with ceresin wax, such as 4 parts pitch, and 1 part ceresin wax, and then thinned out with benzol or toluol. The wax has a tendency to prevent certain grades of pitch being too tacky at low temperatures.

The other surface of the material is provided with a coating 12 of varnish or lacquer, and both sides of the foil may be coated in this manner if the varnish coating is applied before the application of the adhesive. In some instances, the coating of both sides may be found to be desirable. For applying the varnish or lacquer coating the foil may be passed through a bath of the varnish or lacquer, or the coating may be applied by rollers, and thereafter it may be hardened, as by baking at a temperature of about 300° F.

Any suitable varnish may be used, but I prefer a varnish which is acid and alkali resistant. By "resistant" I mean a varnish which will resist the action of alcohol, alkalies and acids in the percentages usually present in beverages or liquids with which the caps are intended to be used. The precise acid and alkali resisting properties of the varnish or lacquer will depend, of course, upon the beverages with which the caps are intended for use, and it will be obvious, of course, to one skilled in the art of producing acid, alkali and alcohol resistant varnishes, that the characteristics of the preferred varnish indicated below may be varied to the extent desired in accordance with the particular purposes of the material.

I have found that for the capping of ordinary beverages containing alkalies and acids, and also alcohol, a varnish comprising a natural gum, such as Zanzibar, Madagascar, or esterized manila gum, together with a relatively large amount of China-wood oil will be very efficient. To make a long oil varnish of this character, I prefer to use thirty-five gallons of oil to one hundred pounds of resinous gum. In such a varnish, metallic driers and plasticizers are added in small amounts, such plasticizers as linseed oil, perilla oil, castor oil, tea seed oil, or lecithin being suitable.

In the manufacture of a foil spot, I have found it advantageous to color the varnish or lacquer, and the use of different and readily distinguishable colors, such as gold and red upon the different types of foil (tin and aluminum) will enable one to determine readily by the color the precise character of the foil. Furthermore, the provision of a colored varnish will conceal the characteristic foil appearance, and thus permit the use of foil in the manufacture of caps for which foil would not ordinarily be regarded as acceptable because of the general impression that a foil spot will not suitably resist acids and alkalies. In order to provide a golden color, for instance, a small amount of gilsonite asphaltum may be incorporated in a varnish of the character above described. The varnish may be brought to the desired consistency by the use of mineral spirits or turpentine substitute.

The foil may be coated either before or after the application of the adhesive, but necessarily preliminary to the application of the

adhesive coating when both sides of the foil are coated with varnish.

By the use of a varnish or lacquer which is resistant to acids (carbonic acid, acetic acid, tartaric acid, citric acid) and which is unaffected by alkalies, alkaline earths and mineral salts, such as sodium chloride, there is provided a foil facing which is suited to the sealing of acidulous beverages which are to be subjected to high temperatures and also to high pressures. A facing of this character is also particularly suited for the sealing of alkaline and saline waters. When coated in this manner, aluminum or other cheap foil can be substituted for tin foil, thereby effecting a substantial economy in the manufacture of the cap.

A cap provided with a spot of this character, namely in which metal foil has its exposed face coated with acid and alkali resistant varnish, is particularly useful in connection with liquids requiring high temperatures for sterilization. For such liquids, paper spot caps even though varnished are not satisfactory, for the reason that varnished paper is permeable, and, therefore, swells and causes the underlying disc or cork to become soggy. As a result, the present invention not only permits the use of cheaper foil, such as aluminum foil for the capping of liquids with which such foils could not heretofore be used, but also permits the use of metal foil spots where paper spots have not been satisfactory even though the paper spots are varnished. That is to say, the varnishing of the foil produces results and affords advantages not obtainable with varnished paper spots and not suggested therefore by the use of varnished paper.

If desired, the adhesive may be applied at the time the varnish coated foil is assembled with the cap, for example, as described in my copending application, Serial No. 360,895, filed May 6, 1929. In this process, the strips of varnish coated foil and adhesive tissue, such as gutta percha, are collated and fed into a punching machine so that superimposed or registering discs of adhesive tissue and spot material are punched from the strips and applied to the cap, heat and pressure being applied to fuse the gutta percha and simultaneously causing adhesion of the same to both the spot disc and the cushion liner in the cap.

In Figures 3 and 4, there is shown a cap made from such a material, whether of the preformed type, shown in Figures 1 and 2, or of the type built up during assembly with the cap. This cap comprises a metallic body or shell 13 of the usual type, having a corrugated skirt 14. Within the cap is a disc of cushion material, such as composition cork 15. This liner or disc is provided with a center spot 16, having its edge spaced from the skirt of the cap to provide a surrounding surface of cushion material, which may directly engage the lip of a bottle, as described in the patent to McManus, No. 1,339,066, granted May 4, 1920.

The disc 16 comprises an exposed layer V of insoluble varnish or lacquer, an intermediate layer F of foil, such as aluminum foil, and a bottom layer A of waterproof adhesive, such as gutta percha. These layers are coextensive in area and afford a laminated center spot.

In some instances, it may be preferable to provide two layers of varnish or lacquer disposed, respectively, at opposite sides of the foil, and a cap having a center spot of this character is shown at Figure 5. In this figure there will be noted, in addition to the layers described in the foregoing description of the cap shown in Figure 4, an additional intermediate layer V′ of varnish. A coating of this character may be conveniently applied by passing the foil through the varnish bath, regardless of whether only a single surface or both surfaces of the foil are to be coated.

Although the material has been described as applied to the cushion material within a cap, it will be understood, of course, that the varnished and adhesively coated foil, or the varnish foil and a separate adhesive strip, such as gutta percha tissue, may be associated with the cushion material before assembly of the latter with the cap, and whether the cushion material is in disc or strip form. Such cushion material may be a composition of cork, newsboard or fibrous material of any character suitable for use in the manufacture of closures.

I claim:

1. A cap having a sealing liner, an interior facing of metal foil on the liner, the facing leaving exposed the surface of the liner around the periphery of the facing, adhesive coextensive with the undersurface of the facing and uniting the same to the liner, and a coating of acid or alkali resistant varnish on the outer surface of the facing.

2. A cap having a sealing liner, an interior facing of metal foil on the liner, the facing leaving exposed the surface of the liner around the periphery of the facing, adhesive coextensive with the undersurface of the facing and uniting the same to the liner, and a coating of acid or alkali resistant varnish on the outer surface of the facing colored to conceal and contrast with the foil surface.

In testimony whereof I have hereunto set my hand.

UNITED STATES PATENT OFFICE

ALBIN H. WARTH, OF BALTIMORE, MARYLAND, ASSIGNOR TO CROWN CORK & SEAL COMPANY, INC., OF BALTIMORE, MARYLAND, A CORPORATION OF NEW YORK

METHOD OF MANUFACTURING LINER MATERIAL FOR CONTAINER CLOSURES

Original application filed January 7, 1927, Serial No. 159,743. Divided and this application filed October 30, 1930. Serial No. 492,304.

My invention relates to material for facing bottle caps and method of making same, and more particularly to strip material having applied to one face thereof a coating of gutta percha.

This application is a division of my application Serial No. 414,614, filed December 17, 1929, now Patent No. 1,899,782, granted February 28, 1933. It is also a continuation-in-part of my copending application Serial No. 494,201, filed November 7, 1930, the said application being a division of my application Serial No. 159,743, filed January 7, 1927, and now Patent No. 1,788,260, granted January 6, 1931.

Heretofore, facing material for bottle caps has been secured in position within the caps by means of gutta percha tissue. In forming the facing disks or center spots and applying them to the caps, the practice has been to cut disks from superimposed strips of facing material and gutta percha tissue, deposit the disks in the cap and apply heat for the purpose of fusing the gutta-percha tissue. Such a method is illustrated and described in my copending application Serial No. 492,546, filed October 31, 1930, as a division of my copending application Serial No. 360,895, filed May 5, 1929, and now Patent No. 1,899,783, granted February 28, 1933. As will be understood, this method of procedure is utilized in the production of caps of the "center spot" type, i. e. which are provided with a facing or "center spot" of less diameter than the cap or cushion disc within the cap. It is to the production of material for the manufacture of caps of this "center spot", that the present invention more particularly relates although in its broader aspects it is useful in the manufacture of caps having facings other than "center spots". A further illustration of a cap of the "center spot" type is to be found in the patent to McManus, No. 1,339,066, granted May 4, 1920. One difficulty in thus applying such center spots or disks to caps has arisen from the use of superimposed unconnected strips of facing material and of gutta percha, the two strips being simultaneously fed from the same roll in relation to the punch of the face applying machine. As will be understood, facings of the "center spot" type are applied within the formed cap to the cushion liner and this method of manufacture presents problems quite distinct from the manufacture of caps having facings co-extensive with the cushion liner, since facings coextensive with the cushion liner are ordinarily produced by adhesively uniting superimposed facing material and cushion liner material, both in sheet form, thereafter simply punching laminated disks of facing material and cushion material from the laminated sheet.

With this condition, there is not only difficulty in feeding the strip, but in cutting the gutta percha with a clean sharp edge so as to ensure the binding stratum of gutta percha being co-extensive in area with the facing disk. The gutta percha binding stratum in such disks is intended not only to act as a cement, but also as a non-absorbent, gas impervious medium for avoiding possibility of the contents of a bottle getting between the facing disk and the material of the cap, either the metal shell itself or a cushion disk of cork or composition cork.

Furthermore, when thus using superimposed strips of the facing material and of gutta percha tissue, it was essential, during the application of the disk to the cap, to bond the gutta percha to both the material of the cap and the facing material.

It is desirable, in the use of facing disks of the character above refered to, that the gutta percha stratum be as thin as possible, and yet be continuous throughout the entire area of the facing disk, and particularly that it be uninterrupted about the edge of this disk, since at this point the disk should be firmly bonded so as to effectively seal the joint about the edge of the facing disk. When cutting and applying the disks of paper and gutta percha, there is no means of ascertaining whether the desired conditions are present in the completed cap. Consequently, there is always likelihood of imperfectly faced caps being produced.

With the above conditions in mind, I have provided material, in strip form, for facing bottle caps, in which one surface of the strip

is provided with a firmly adherent, continuous thin facing of gutta percha, thus avoiding all necessity for assembling strips of facing material and of gutta percha tissue preparatory to their use in the bottle cap facing machine, and all of the disadvantages growing out of this practice.

In the strip material of my invention, a very thin stratum of gutta percha is evenly distributed upon one face of a strip of facing material. The gutta percha is not only firmly bonded to this material, but is forced into the surface grain thereof, and has a smooth surface finish of sufficient thickness to form the desired firm bond between a disk cut from the strip and the material of the cap to which such disk is cemented.

The manner of applying the gutta percha to the facing strip is such as to ensure substantial uniformity in the condition of the gutta percha throughout the strip by reason of the fact that those impurities or imperfections resulting from the working of gutta percha in a mill will develop only along the edges of the facing material, where they may either be removed by trimming wide strips of the material, or will come within the wastage of narrow strips when cutting disks from such strips.

Furthermore, gutta percha tissue must be of a thickness to have sufficient inherent strength to permit of its being stripped from a roll in a mill for working same, and to admit of its being cut to the desired width and to be handled in the re-winding and the disk applying machines, and during the process of its production it has more or less of a longitudinally extending grain as distinguished from its normal granular formation.

In applying the gutta percha to the fibrous or metallic facing material in accordance with my invention, the thickness of the gutta percha is determined solely by that required to secure the desired intermediate stratum of the gutta percha in the finished cap.

In the application of heat, when bonding the facing material to the cap, when utilizing gutta percha tissue, a tendency of the gutta percha is to break up into slightly isolated, small globules, thus interrupting the continuity of the bonding stratum. Whether this is due to irregularities in the surface of the facing strip, or to a shrinkage of the gutta percha tissue when fused, I have been unable to determine. In the strip of my invention, however, the gutta-percha is thoroughly distributed throughout one face of the facing material, and the above conditions do not develop in the subsequent handling of the strips.

So far as the method of producing the strip is concerned, it is such that the effective distribution of the gutta percha throughout the entire area of the facing material is assured, and this condition cannot be disturbed as a result of the cutting of disks from this material when in strip form. Furthermore, the gutta percha surface may be thoroughly inspected while producing the strip material, so that any imperfect product may be discarded before it reaches the disk applying machine.

It is desired to note that the surface of the strip to which the gutta-percha is not applied is always a highly polished surface, whether it be a varnish fibrous material such as paper, or a metal foil, so that the gutta percha surface will not adhere thereto. By applying the gutta percha directly to the surface of the paper and firmly bonding it there is not liklihood of difficulties arising as a result of the separation of the gutta percha from the facing strip during the unwinding operation, either as a result of slight adherence, from suction or otherwise, such as frequently occurs when using the superimposed strips of the facing material and of gutta percha tissue.

The invention consists primarily in a method of producing material for facing bottle caps consisting of a facing strip of nonabsorbent, gas impervious and acid resisting material such as resistant varnished paper or metal foil having bonded thereto, throughout one face thereof, a thin surfacing of heat fusible adhesive, such as gutta percha, all as hereinafter set forth and described, and more particularly pointed out in the claims hereto appended.

Referring to the drawing,

Figure 1 is a diagrammatic showing of the method of producing the facing material of the invention.

Figure 2 is a longitudinal view, partly in cross section, of a fragmentary portion of said material.

Fig. 3 is a face view thereof with a portion of the facing strip broken away.

Fig. 4 is a vertical sectional view illustrating the method of applying the material to a cap, and

Fig. 5 is a vertical sectional view showing the cap with the spot applied.

Like letters refer to like parts throughout the several views.

In the accompanying drawing, the thickness dimensions are all greatly exaggerated, the thickness of the facing strip being less than five thousandths of an inch, and that of the gutta-percha surfacing less than two thousandths of an inch.

In the embodiment of the invention shown in the drawing, the facing strip is composed of what is known as express paper which is a resistant or hard, tough paper having little absorptive properties. The properties inherent to the paper, however, are such, if properly finished, as to adapt it for use as facing material for bottle caps, although it is extremely difficult to satisfactorily cement

such paper to the metal shell or cork cushion of such a closure.

In order to impart to one surface of the paper only the desired properties which will result in this strip presenting toward the contents of a bottle, a surface which is non-absorbent, gas impervious and acid resisting, I give a finish to this surface consisting of a coating of a varnish having the desired properties, and which includes therein resin, Chinawood oil, a drier and a plasticizer. This surface finish, in addition to having the properties above described, will also be sufficiently flexible to avoid the formation of cracks, or impart to the paper strip as a whole, a degree of brittleness which might result in the formation of such cracks or seams in the paper as would destroy the surface finish and permit the contents of the bottle to attack the body of the paper.

While express paper is a water finish paper, other similar papers may be used such as sulfite paper or bleached kraft paper.

The varnish finish coating above referred to is indicated at *b* in the drawing, this coating being very thin, merely sufficient to provide a continuous surface upon one side of the strip. The other side of the paper strip presents the normal finish of the paper, and has firmly bonded thereto a thin coating *c* of gutta percha, covering the entire face of the strip and presenting a smooth continuous surface, having a general granular character resulting from the manner of applying same to the paper.

It is obvious that in the handling of the completed strip of facing material the gutta percha facing *c* will be incapable of stretch or distortion because of its firm adherence to the non-elastic paper strip *a*. As compared with gutta percha tissue, the quantity of gutta percha required to secure the desired bonding action, when assembling the facing disk in a cap, is somewhat reduced.

In cutting disks from a strip of the material, there is no tendency toward mutilation of the gutta percha by reason of possible drag in the cutting dies, and each disk, as delivered from the die to within a cap, will present a continuous uninterrupted gutta percha surface upon the disk, so as to ensure, by the subsequent application of heat and pressure, a bond between the disk and the cap co-extensive in area with the disk.

In Fig. 4 there is shown a convenient arrangement for applying the disk to the cap. The cap 10 is of the type having an interior facing 11 of cushion material, such as composition cork, and is shown as arranged beneath cutting dies *j*, *k*. The paper in strip form is fed beneath the die *j* with the gutta-percha coating *c* facing the cap. With the descent of the punch *j* the disk is cut from the strip and pressed by the punch upon the cap which may be supported by any suitable means (not shown). As illustrated in Figs. 4 and 5, the disk is preferably of smaller diameter than the cap liner so as to form a substantially centrally disposed spot. The punch *j* may be maintained at elevated temperature, as by means of the burner *l*; the temperature should be sufficient to fuse the gutta-percha coating and make it tacky so that practically simultaneously with the pressing of the disks against the cap facing, the same will be adhesively united to the cap with sufficient permanency to insure accurate positioning of the disk and avoid likelihood of displacement of the same thereafter. As will be understood, when the cap is removed from the heated zone, the gutta-percha will harden and thereby firmly retain the disk in position as illustrated in Fig. 5.

Since, in applying the gutta percha to the paper, the conditions are such as to completely fill all surface pores, it is obvious that during the bonding action, in the facing machine there is no tendency of the gutta percha, during and after fusing, leaving exposed, minute openings at any point of the surface of the paper.

By reason of the thinness of the gutta percha facing *c* there is no tendency toward the expression of any of the gutta percha from between the facing disk and the portion of the cap to which it is applied.

The possibility of securing a clean cut by the dies for forming the disks, both as to the paper and as to the gutta percha facing *c*, ensures an effective bond entirely about the edge of the disk, presenting a continuous barrier of non-absorptive, gas impervious and acid resisting material at the space between the disk and the cap which will effectively prevent the seepage of the gas or fluids in a bottle between the disk and the portion of the cap to which it is applied.

In Fig. 1 of the drawing, I have illustrated the method of making the strip material of my invention. In the practice of this method, I use an ordinary mill with its heated rollers *d* and *e*. Operative in relation to the lower roller *e* is a backing roller *f*. A strip of the paper or other material *a* is drawn between the rollers *e* and *f* by means of the feed rollers *g*, by which it is passed to a re-wind mechanism indicated at *h*.

The method contemplates the feeding of the strip *a* between a backing roller *f*, and between one of the heated rolls, of a gutta percha mill *e*, thus applying a thin coating of gutta percha while hot, to one surface only of the paper strip *a*, the gutta percha hardening from its exposure to the surrounding temperature before engagement by the feed rollers *g*.

In feeding the strip *a* in the manner above described, the varnish surface thereof is presented downwardly, this surface having been applied to the paper prior to the feeding

of the strip in the mill. In this manner a very thin coating of gutta percha may be applied to one face of the strip *a*, to which it will firmly adhere while said strip is passing between the rollers *e* and *f*.

The thickness of the surface coating may be controlled by adjustment of the rollers *d* and *e*, and also by adjustment of the roller *f* in relation to the latter. In this manner, the strip *a* will have applied thereto a surfacing of gutta percha which will be evenly distributed through the entire surface of the strip, and will present a substantially smooth exterior surface, notwithstanding surface irregularities in the paper itself. The smooth polished surface *c* will avoid any possibility of a surface stratum *c* adhering to the adjoining stratum *b* after the strip is re-wound and while it is being unwound in the disk applying machine, since the gutta percha will not become tacky under normal factory temperatures.

It is preferable to apply the gutta percha in the manner above described, to wide strips of paper which are cut into narrower strips of the desired width for use with bottle caps of different diameters.

The method described has been found to be applicable to the coating of paper strips with gutta percha; if used to coat metal foil it may be desirable to employ a previous preparation of one surface of the foil to receive the gutta percha and permit it to adhere thereto with sufficient strength to permit a continuing application of gutta percha to a strip as required by the method of my invention.

Facing material embodying the invention possesses the advantages that a substantially uniform and complete distribution of the gutta percha throughout each disk cut from a strip, is assured. The additional labor of associating a strip of gutta percha tissue and a strip of facing material is avoided, and higher speeds may be attained in the facing disk applying machine. By the method of applying fused gutta percha to a facing strip, there is considerable saving, not only by the reduction in the amount of gutta percha required, as compared with the use of gutta percha tissue, but the preparation of the strips for use in the disk applying machines is very much reduced, and a more uniform quality in the bond between the disks and the caps is also assured.

I claim:

1. The herein described method of making a bottle cap liner material which consists in applying a thin stratum of fused gutta-percha to substantially the entire of one surface of a continuous strip of facing material selected from a group consisting of metallic foil and varnished coated tough paper having relatively low absorptive properties, while subjecting said material and said gutta-percha to sufficient pressure to cause the gutta-percha to conform with, and adhere to, the surface of said material, and then cutting the coated strip into narrower strips of the width desired.

2. The herein described method of making a bottle cap liner material which consists in moving a continuous strip of resistant material selected from a group consisting of metallic foil and varnished coated tough paper having relatively low absorptive properties across a cold backing roll in operative relation to a heated roll of gutta-percha mill, and applying a thin coating of fused gutta-percha to substantially the entire of one surface of said strip by subjecting said strip and said gutta-percha to sufficient pressure to cause the gutta-percha to conform with, and adhere to, the surface of said material, and then cutting the coated strip into narrower strips of the width desired.

3. The herein described method of making a bottle cap liner material which consists in moving a continuous strip of relatively hard, tough paper having relatively low absorptive properties across a cold backing roll in operative relation to a heated roll of a gutta-percha mill, and applying a thin coating of fused gutta-percha to said strip by subjecting said strip and said gutta-percha to sufficient pressure to cause the gutta-percha to conform with, and adhere to, the surface of said material, providing the other surface of the paper with a coating of varnish, and cutting the varnished and gutta percha coated strip to narrower strips of the width desired.

4. The improved method of making a bottle cap liner material which consists in providing a strip of material which is waterproof and acid resistant selected from a group consisting of metallic foil, and hard, tough paper having relatively low absorptive properties and forming on one surface thereof a continuous coextensive coating of adhesive which is normally hard or nontacky at room temperature but softens upon the mere application of heat, and cutting the varnished and gutta-percha coated strip to narrower strips of the width desired.

5. The improved method of preparing for crown caps facing material in strip form adapted to have center spot disks punched therefrom and applied to the cap by the mere application of heat and pressure which consists in providing highly flexible material selected from a group consisting of metallic foil or varnished coated tough paper having relatively low absorptive properties, coating the entire of one surface of said material while in the form of sheets having several times the width of the final strip desired with a continuous thin adherent and coextensive layer of adhesive which is fusible upon the mere application of heat, impervious to water, highly flexible, and substantially non-tacky

at room temperature, and then cutting the coated sheet into narrow strips.

6. The improved method of preparing for crown caps facing material in strip form adapted to have center spot disks punched therefrom and applied to the cap by the mere application of heat and pressure which consists in providing highly flexible material selected from a group consisting of metallic foil or varnished coated tough paper having relatively low absorptive properties, moving said material in sheet form having several times the width of the final strip desired in operative relation to a heated roll of a gutta percha mill and applying to substantially the entire of one surface thereof of thin coating of fused gutta percha by subjecting the sheet to sufficient presure to cause the gutta percha to conform with and adhere to the surface of said material, and then cutting the coated sheet into relatively narrow strips of the width desired.

7. The improved method of preparing for crown caps facing material in strip form adapted to have center spot disks punched therefrom and applied to the cap by the mere application of heat and pressure which consists in providing highly flexible metallic foil, coating substantially the entire of one surface of said foil while in the form of a sheet having several times the width of the final strip desired with a continuous thin, adherent and coextensive layer of gutta percha fusible upon the mere application of heat, and then cutting the coated sheet into relatively narrower strips.

8. The improved method of preparing for crown caps facing material in strip from adapted to have center spot disks punched therefrom and applied to the cap by the mere application of heat and pressure which consists in providing highly flexible metallic foil, coating substantially the entire of one surface of said foil while in the form of a sheet having several times the width of the final strip desired with a continuous thin, adherent and coextensive layer of adhesive which is fusible upon the mere application of heat, impervious to water, highly flexible, and substantially non-tacky at room temperature, and then cutting the coated sheet into narrow strips.

9. The improved method of preparing for crown caps facing material in strip form adapted to have center spot disks punched therefrom and applied to the cap by the mere application of heat and pressure which consists in providing highly flexible metallic foil, moving said foil in sheet form having several times the width of the final strip desired in operative relation to a heated roll of a gutta percha mill and applying to substantially the entire of one surface thereof a thin coating of fused gutta percha by subjecting the sheet to sufficient pressure to cause the gutta percha to conform with and adhere to the surface of said material, and then cutting the coated sheet into relatively narrow strips of the width desired.

In testimony whereof I have hereunto set my hand.

UNITED STATES PATENT OFFICE

ALBIN H. WARTH, OF BALTIMORE, MARYLAND, ASSIGNOR, BY MESNE ASSIGNMENTS, TO CROWN CORK & SEAL COMPANY, INC., OF NEW YORK, N. Y., A CORPORATION OF NEW YORK

PROCESS OF PRODUCING CLOSURES

REISSUED

Application filed January 7, 1927. Serial No. 159,743.

This invention relates to a method of producing closures of the type in which a sealing disk has a metal foil facing. This type of closure is characterized by the provision, upon the interior cushion or sealing disc, of a facing or spot having a surface which protects the cushion material from the liquids and gases.

Closures of the well known crown cork type comprise a metal shell having a skirt and a resilient sealing disk usually made of cork. For some uses, the sealing disks are given a non-absorbent, gas impervious and acid resistant facing of metal foil, e. g. tin foil, or aluminum foil. Aluminum foil is characterized by the fact that it is substantially non-absorbent and gas impervious, and for this reason the same and other materials having similar characteristics are used to form facing disc or spots upon the cushion material of crown caps. Ordinarily this facing is of smaller diameter than the cork disks and such crowns are known in the trade as spot center crowns.

These spot center crowns have been produced in various ways. According to one method a slot or groove is cut in the cork disk and the spot is given an inturned rim which is inserted in the slot. This method is objectionable because of its expense and because the spots are apt to drop out. According to another method the spots are pasted to the cork disks by a casein paste or a glue. In crowns so made the spots tend to loosen as the paste or glue is attacked by the packaged liquids. Furthermore, such method involves difficulties in handling and in applying the paste or glue. According to still another method the spots are secured by an underlying tissue of gutta percha or coated paper. In crowns so made, like objections are met with. For example, one difficulty in applying discs made from separate strips, such as gas and acid resistant material and the adhesive tissue strips, has arisen from the necessity for feeding the two strips to the punching and assembly machine. There is not only difficulty in feeding the strips, but in cutting the separate tissue strip with a clean, sharp edge so as to insure the binding stratum of adhesive being coextensive in area with the disc of liquid resistant material. As will be understood, the adhesive stratum is intended to act not only as a cement, but also as a waterproof, non-absorbent, gas impervious medium for avoiding the possibility of the contents of a bottle getting between the facing disc and the material of the cap, either the metal shelf itself or a cushion disc of cork or composition cork.

Furthermore, when using superimposed strips of the facing material and of adhesive tissue, it was essential, to bond the adhesive tissue to both the material of the cushion disc in the cap and the facing material.

In preparing the rolls of facing material and adhesive tissue, the practice usually followed was to form a roll of the tissue in strips of the desired width, and to unwind this roll and a roll of the facing material while feeding the two strips one over the other into the disc forming and assembling machine. This is a troublesome and expensive operation, because of the frequent breakage of the adhesive tissue and the necessity for using fairly heavy tissue to minimize this tendency. This is due partly to the fact that the facing material was substantially non-elastic, while the adhesive tissue possessed a certain degree of elasticity, thus introducing a factor of difficulty in securing a uniform paying of both the facing strip and the gutta percha tissue strip.

It is desirable, in the use of facing disks of the character above referred to, that the adhesive stratum be as thin as possible, and yet be continuous throughout the entire area of the facing disk, and particularly that it be uninterrupted about the edge of this disk, since at this point the disk should be firmly bonded so as to effectively seal the joint about the edge of the facing disk. When cutting and applying the disks of material and adhesive, there is no means of ascertaining whether the desired conditions are present in the completed cap. Consequently, there is always likelihood of imperfectly faced caps being produced.

With the above conditions in mind, I have provided material, in strip form, for facing

bottle caps, in which one surface of the strip is provided with a firmly adherent, continuous thin facing of adhesive, thus avoiding all necessity for assembling strips of facing material and of adhesive tissue preparatory to their use in the bottle cap facing machine, and all of the disadvantages growing out of this practice.

In the strip material of my invention, a very thin stratum of adhesive is evenly distributed upon one face of a strip of facing material. The adhesive is not only firmly bonded to this material, but has a smooth surface finish of sufficient thickness to form the desired firm bond between a disk cut from the strip and the material of the cap to which such disk is cemented.

Furthermore, adhesive tissue must be of a thickness to have sufficient inherent strength to permit of its being stripped from a roll in a mill for working same, and to admit of its being cut to the desired width and to be handled in the winding and the disk applying machines, and during the process of its production it has more or less of a longitudinally extending grain, as distinguished from its normal granular formation.

In the application of heat, when bonding the facing material to the cap, when utilizing adhesive tissue, a tendency of the adhesive is to break up into slightly isolated, small globules, thus interrupting the continuity of the bonding stratum. Whether this is due to irregularities in the surface of the facing strip, or to a shrinkage of the adhesive tissue when fused, I have been unable to determine. In the strip of my invention, however, the adhesive is thoroughly distributed throughout one face of the facing material, and the above conditions do not develop in the subsequent handling of the strips.

It is an object of the present invention to provide a method of producing spot center crowns such that the spots are easily and economically secured to the sealing disks and such that they are firmly secured and not liable to become loosened in use.

With these general objects in view the invention consists in the method which will be first described and then more particularly pointed out in the claims.

According to the method of the present invention, the strip material having a surface which is substantially non-absorbent and gas impervious, such as metal foil, is coated with a substance that is devoid of tackiness when dry and has adhesive qualities when soft. In carrying out the method according to what is considered the best practice the adhesive substance is such that it can be applied cold, i. e. at room temperatures, and is waterproof or insoluble in cold water. While various materials may be used I have found a suitable adhesive in a solution of damar gum and rosin in mineral spirit or turpentine, to which is added 5% or less of a vegetable oil such as soya bean or China-wood oil. The damar gum and rosin may be in the proportion of 35% to the whole. The adhesive may have a drier of lead resinate or the like in a proportion of 2% or less. This adhesive is waterproof and is not weakened by gases or acids, such as are present in the bottle contents with which crown caps are usually employed.

While the coating may be applied to the material in various ways, it is conveniently applied in fluid form and cold to a strip of foil from which the spots are to be cut. So far as the method of producing the strip is concerned, it is such that the effective distribution of the adhesive throughout the entire area of the facing material is assured, and this condition cannot be disturbed as a result of the cutting of discs from this material when in strip form. Furthermore, the adhesive surface may be thoroughly inspected while producing the strip material, so that any imperfect product may be discarded before it reaches the disc applying machine. In this connection it is noted that the spots may be conveniently assembled by feeding a strip of material over successive crown corks and cutting out a disk which is deposited on a cork, such assembling machinery being known in the art.

After the coating is applied to the metal foil it is dried. While this may be effected by air drying at room temperature it is more rapidly accomplished at a temperature of about 300° F. maintained for about 30 minutes. When dried the coating is devoid of tackiness so that the metal foil may be handled without difficulty or trouble. This is particularly advantageous when the metal foil is to be fed in strips because the application of the adhesive is carried out independently of the assembling steps. Moreover, the coating gives the thin metal foil more or less body which facilitates feeding and cutting. Since the adhesive is applied directly to the surface of the facing or spot material and firmly bonded thereto, there is no likelihood of difficulties arising as a result of separation of the adhesive from the facing strip during the spot forming operation, either as a result of poor adherence or from suction or otherwise, such as frequently occurs when using superimposed strips of facing material and of adhesive tissue. Moreover, in handling this material the adhesive stratum is incapable of stretch or distortion relative to the spot strip as frequently occurs in the handling of separate strips of adhesive tissue and facing material where any stretch or distortion of the adhesive stratum results in a defective cap and when the stretch is extreme, tearing of the adhesive tissue makes necessary the stoppage of the cap machine until the strip can be repaired.

After the coating is dry, the metal foil spots

are assembled, coated side down, with the sealing disks. In case the metal foil is fed in a strip, spots may be cut out and deposited on the sealing disk, as above set forth.

At the time of assembly the coating material is softened to render it adhesive and the assembled unit is subjected to pressure. In carrying out the invention according to what is now considered the best practice the coating will be softened by heat after the crown is assembled. In cutting discs from this improved laminated strip having an adhesive stratum bonded thereto, there is no tendency toward mutilation of the adhesive layer by reason of possible drag of the cutting dies, and each disc, as delivered from the die to within a cap, will present a continuous uninterrupted adhesive surface upon the disc so as to insure, by the subsequent application of heat and pressure, a bond between the disc and the cap cushion layer coextensive in area with the disc.

This possibility of securing a clean cut by the dies for forming the discs, both as to the non-absorptive and gas impervious, and as to the adhesive stratum, insures an effective bond entirely about the edge of the spot or disc, thereby presenting a continuous barrier of non-absorptive and gas impervious material at the space between the disc and the cap which will effectively prevent the seepage of gas or fluid in a bottle between the disc and the portion of the cap to which it is applied.

Although the adhesive facing is sufficiently thick to provide an adhesive stratum or layer, it is sufficiently thin to avoid any tendency toward the expression during the application of pressure of any of the adhesive from between the facing material and the portion of the cap to which it is applied. This may be accomplished in any suitable manner, as by a heated plunger or a plunger and heated table. The heat softens the coating and renders it adhesive and the pressure serves to unite the metal foil spot to the cork.

Referring to the accompanying drawings, there is shown suitable mechanism for coating the strip and for cutting discs therefrom and adhesively uniting the disc to caps at the time of the assembly of the discs with the caps. In the drawings,

Figure 1 is a diagrammatical view showing the coating of the strip.

Figure 2 is a longitudinal sectional view of a fragment of the strip.

Figure 3 is a side elevational view partly in section showing one step in the assembly operation.

Figure 4 is a view similar to Figure 3 showing the spot as it is cut and adhesively united to the cap at the time of assembly.

Figure 5 is an interior face view of the completed cap, and

Figure 6 is a cross sectional view of the cap shown in Figure 5.

The strip of facing material should have the characteristic of aluminum foil. That is to say, it should present one surface which is non-absorbent and gas impervious. This strip may be fed from a reel 10 to a reel 11, suitably separated so that the adhesive coating may be applied and hardened between the time any portion of the strip leaves the reel 10 and is wound upon the reel 11. For the purpose of applying the adhesive, the same may be maintained in a trough 12, positioned beneath an adhesive applying roll 13, between which and a roll 14, the strip passes, so that as the rolls are rotated the adhesive is applied to the undersurface thereof. As will be understood, the adhesive hardens between the time it is applied and the winding of the laminated strip upon the reel 11.

The completed spot material or liner is illustrated in Figure 2, and comprises the layer 15 of non-absorbent and gas impervious material, such as aluminum foil having on one surface the coating 16 of adhesive, which is preferably of the character hereinbefore described. This adhesive is waterproof or liquid resistant, and will be normally hard, i. e. non-tacky, at room temperature so that the material may be conveniently handled in strip form, but quickly softens under the application of heat, becoming tacky, so that upon the application of pressure, the laminated disc will be adhesively retained in the cap. The preferred method of applying the material to the cap is to utilize, at the time of assembly, both heat and pressure to unite the spot to the cork or cushion material insert or facing of the cap.

In Figures 3 and 4, there is shown a suitable mechanism for applying the disc and adhesively uniting it to the cork insert at the time the strip is punched from the disc and assembled with the cap.

The cap 17 is of the conventional crown type having an interior facing 18 of cushion material, such as composition cork retained in the cap as by an adhesive layer 17′; the cushion disc and adhesive may be applied to the cap in any suitable manner, for example as described in the patent to Marsa, No. 1,603,786, granted Oct. 19, 1926. The caps, with the cushion discs inserted therein, may be positioned beneath the cutting dies 19, 20, by means of a traveling bed 21 having suitable sockets for receiving the cap so as to position the same accurately beneath the cutting dies. The strip material for forming the spot is fed beneath the die 20 with the adhesive coating 16 facing the cap, and when the die descends it will cut from the strip, which is fed by any suitable means (not shown), a spot or facing 22 of the character illustrated in Figures 5 and 6. The spot or disc is preferably of smaller diameter than the cap facing so as to form a substantially centrally

disposed spot which leaves around its edge an exposed portion of the cushion material adapted to engage the edge of a bottle neck, the spot being of sufficient size to close the bottle mouth and prevent contact of the contents with the cushion material.

As will be observed (Figures 3 and 4) as the punch 20 descends, it cuts from the strip a spot of the size shown in Figure 5, and continued downward movement presses this disc upon the cushion layer 18.

The punch 20 may be maintained at an elevated temperature, as by means of a burner 23, and the temperature should be sufficient to fuse or soften the adhesive coating and make it tacky so that, at the time the disc is assembled with the cap, the heat and pressure will cause the disc to be adhesively united to the surface of the cushion material with sufficient permanency to insure that the position will be retained and avoid likelihood of displacement of the disc thereafter.

The assembled unit is then permitted to cool and the cooling may advantageously be coupled with pressure, for example, by a plunger. Cooling may be effected in any suitable manner, being carried out to the congealing point of the coating material.

The resulting crown has a firmly secured metal foil spot which is not liable to become loose in use owing to the fact that the adhesive substance is not soluble in liquids more commonly sealed by crown corks. Moreover, when the metal foil is assembled with the sealing disk it is already prepared for being stuck in place, the sticking being accomplished by the simple application of heat and pressure. The coating operation is a simple one and the coated metal foil is easily handled because the dry coating is not tacky.

A cap made in accordance with this method possesses the advantage of a substantially uniform and complete distribution of the adhesive layer throughout each spot or facing disc. The method has the advantage of eliminating the labor of associating a separate adhesive strip and a strip of facing material, and the further advantage of enabling higher speeds to be maintained in the facing spot applying machine. The elimination of the danger of breakage of a separate adhesive tissue strip avoids the frequent stoppage of the machine, which was unavoidable due to the handling of the somewhat fragile and elastic adhesive tissue.

What is claimed is:

1. The improved method of manufacturing caps of the type having an interior disc of cushion material provided on its exposed face with a center spot, which comprises providing spot material in strip form having one surface formed of an exposed continuous coating of water resistant adhesive which is normally hard at room temperature but becomes tacky upon the application of heat and having another surface to be exposed to the contents of a capped container, cutting from said strip a facing spot having one surface completely coated with said adhesive with a cap disposed beneath the portion of the strip from which the spot is cut, whereby the cutting operation positions the spot upon the cushion material with the coating between the spot and the cushion material, and upon assembly applying simultaneously to the spot pressure and sufficient heat to render the adhesive tacky, thereby causing the spot to adhere to the cushion material, and thereafter permitting the adhesive to cool and harden.

2. The improved method of manufacturing caps of the type having an interior disc of cushion material provided on its exposed face with a center spot, which comprises providing metal foil spot material in strip form having one surface formed of an exposed continuous coating of water resistant adhesive which is normally hard at room temperature but becomes tacky upon the application of heat and having another surface to be exposed to the contents of a capped container, cutting from said metal foil strip a facing spot having one surface completely coated with said adhesive with a cap disposed beneath the portion of the strip from which the spot is cut, whereby the cutting operation positions the spot upon the cushion material with the coating between the spot and the cushion material, and upon assembly applying simultaneously to the spot pressure and sufficient heat to render the adhesive tacky, thereby causing the spot to adhere to the cushion material, and thereafter permitting the adhesive to cool and harden.

In testimony whereof, I have hereunto set my hand.

ALBIN H. WARTH.

Patent 1,782,782

TO THE COMMISSIONER OF PATENTS:-

Your petitioner, Albin H. Warth, a citizen of the United States, residing at Baltimore, in the County of Baltimore and State of Maryland, (whose Post Office address is 29 York Court, Baltimore, Md.) prays that Letters Patent may be granted to him for the new and useful Improvements in Material for Facing Bottle Caps and Method of Making Same, set forth in the annexed specification; and he hereby appoints Frank T. Wentworth, of 41 Park Row, in the Borough of Manhattan, City, County and State of New York, his attorney with full power of substitution and revocation, to prosecute this application, to make alterations and amendments therein, to sign the drawings, to receive the patent, and to transact all business in the Patent Office connected therewith.

Signed at Baltimore, in the County of Baltimore and State of Maryland, this 11th day of December 1929.

Albin H. Warth

TO ALL WHOM IT MAY CONCERN:-

Be it known that I, Albin H. Marth, a citizen of the United States, residing at Baltimore, in the County of Baltimore and State of Maryland, have invented certain new and useful Improvements in Material for Facing Bottle Caps and Method of Making Same, of which the following is a specification, reference being had therein to the accompanying drawings, which form a part thereof.

My invention relates to material for facing bottle caps and method of making same, and more particularly to strip material having applied to one face thereof a coating of gutta-percha.

Heretofore, facing material for bottle caps has been secured in position within the caps by means of gutta-percha tissue. In forming the facing disks and applying them to the caps, the practice has been to cut disks from superimposed strips of facing material and gutta-percha tissue, deposit the disks in the caps and apply heat for the purpose of fusing the gutta-percha tissue. One difficulty in thus applying such disks to caps has arisen from the use of superimposed unconnected strips of facing material and of gutta-percha, the two strips being simultaneously fed from the same roll in relation to the punch of the face applying machine.

With this condition, there is not only difficulty in feeding the strip, but in cutting the gutta-percha with a clean sharp edge so as to ensure the binding stratum of gutta-percha being co-extensive in area with the facing disk. The gutta-percha binding stratum in such disks is intended not only to act as a cement, but also as a non-absorbent, gas impervious medium for avoiding possibility of the contents of a bottle getting between the facing disk and the material of the cap,

either the metal shell itself or a cushion disk of cork or composition cork.

Furthermore, when thus using superimposed strips of the facing material and of gutta-percha tissue, it was essential, during the application of the disk to the cap, to bond the gutta-percha to both the material of the cap and the facing material.

In preparing the rolls of facing material and gutta-percha tissue, the practice usually followed was to form a roll of the tissue in strips of the desired width, and to unwind this roll and a roll of the facing material and pass them through a re-winding machine. This is a troublesome and expensive operation because of the frequent breakage of the gutta-percha tissue if the re-winding machine be operated at too high a speed, and the necessity for using fairly heavy tissue to minimize this tendency. This is due partly to the fact that the facing material was substantially non-elastic, while the gutta-percha possessed a certain degree of elasticity, thus introducing a factor of difficulty in the re-winding machine in securing a uniform paying out of both the facing strip and the gutta-percha tissue strip.

It is desirable, in the use of facing disks of the character above referred to, that the gutta-percha stratum be as thin as possible, and yet be continuous throughout the entire area of the facing disk, and particularly that it be uninterrupted about the edge of this disk, since at this point the disk should be firmly bonded so as to effectively seal the joint about the edge of the facing disk. When cutting and applying the disks of paper and gutta-percha, there is no means of ascertaining whether the desired conditions are present in the completed cap. Consequently, there is always likelihood

of imperfectly faced caps being produced.

With the above conditions in mind, I have provided material, in strip form, for facing bottle caps, in which one surface of the strip is provided with a firmly adherent, continuous thin facing of gutta-percha, thus avoiding all necessity for assembling strips of facing material and of gutta-percha tissue preparatory to their use in the bottle cap facing machine, and all of the disadvantages growing out of this practice.

In the strip material of my invention, a very thin stratum of gutta-percha is evenly distributed upon one face of a strip of facing material. The gutta-percha is not only firmly bonded to this material, but is forced into the surface grain thereof, and has a smooth surface finish of sufficient thickness to form the desired firm bond between a disk cut from the strip and the material of the cap to which such disk is cemented.

The manner of applying the gutta-percha to the facing strip is such as to ensure substantial uniformity in the condition of the gutta-percha throughout the strip by reason of the fact that those impurities or imperfections resulting from the working of gutta-percha in a mill will develop only along the edges of the facing material, where they may either be removed by trimming wide strips of the material, or will come within the wastage of narrow strips when cutting disks from such strips.

Furthermore, gutta-percha tissue must be of a thickness to have sufficient inherent strength to permit of its being stripped from a roll in a mill for working same, and to admit of its being cut to the desired width and to be handled in the re-winding and the disk applying, machines, and during the

process of its production it has more or less of a longitudinally extending grain as distinguished from its normal granular formation.

In applying the gutta-percha to the fibrous or metallic facing material in accordance with my invention, the thickness of the gutta-percha is determined solely by that required to secure the desired intermediate stratum of the gutta-percha in the finished cap.

In the application of heat, when bonding the facing material to the cap, when utilizing gutta-percha tissue, a tendency of the gutta-percha is to break up into slightly isolated, small globules, thus interrupting the continuity of the bonding stratum. Whether this is due to irregularities in the surface of the facing strip, or to a shrinkage of the gutta-percha tissue when fused, I have been unable to determine. In the strip of my invention, however, the gutta-percha is thoroughly distributed throughout one face of the facing material, and the above conditions do not develop in the subsequent handling of the strips.

So far as the method of producing the strip is concerned, it is such that the effective distribution of the gutta-percha throughout the entire area of the facing material is assured, and this condition cannot be disturbed as a result of the cutting of disks from this material when in strip form. Furthermore, the gutta-percha surface may be thoroughly inspected while producing the strip material, so that any imperfect product may be discarded before it reaches the disk applying machine.

It is desired to note that the surface of the strip to which the gutta-percha is not applied is always a highly polished surface, whether it be a varnish fibrous material such

as paper, or a metal foil, so that the gutta-percha surface will not adhere thereto. By applying the gutta-percha directly to the surface of the paper and firmly bonding it there is no likelihood of difficulties arising as a result of the separation of the gutta-percha from the facing strip during the unwinding operation, either as a result of slight adherence, from suction or otherwise, such as frequently occurs when using the superimposed strips of the facing material and of gutta-percha tissue.

The invention consists primarily in material for facing bottle caps consisting of a facing strip of non-absorbent, gas impervious and acid resisting material, having bonded thereto, throughout one face thereof, a thin surfacing of gutta-percha; and in such other novel characteristics, and in the novel steps and practices of producing same, all as hereinafter set forth and described, and more particularly pointed out in the claims hereto appended.

Referring to the drawings,

Fig. 1 is a diagrammatic showing of the method of producing the facing material of the invention;

Fig. 2 is a longitudinal view, partly in cross section, of a fragmentary portion of said material; and

Fig. 3 is a face view thereof with a portion of the facing strip broken away.

Like letters refer to like parts throughout the several views.

In the accompanying drawings, the thickness dimensions are all greatly exaggerated, the thickness of the facing strip being less than five thousandths of an inch, and that of the gutta-percha surfacing, less than two thousandths of an inch.

In the embodiment of the invention shown in the draw-

ing, the facing strip is composed of what is known as Express paper which is a hard, tough paper having little absorptive properties. The properties inherent to the paper, however, are such, if properly finished, as to adapt it for use as facing material for bottle caps, although it is extremely difficult to satisfactorily cement such paper to the metal shell or cork cushion of such a closure.

In order to impart to one surface of the paper only the desired properties which will result in this strip presenting toward the contents of a bottle, a surface which is non-absorbent, gas impervious and acid resisting, I give a finish to this surface consisting of a coating of a varnish having the desired properties, and which includes therein resin, China-wood oil, a drier and a plasticizer. This surface finish, in addition to having the properties above described, will also be sufficiently flexible to avoid the formation of cracks, or impart to the paper strip as a whole, a degree of brittleness which might result in the formation of such cracks or seams in the paper as would destroy the surface finish and permit the contents of the bottle to attack the body of the paper.

R.B While Express paper is a water leaf finish paper, other similar papers may be [illegible] such as Sulfite paper or Bleached Kraft paper.

The varnish finish coating above referred to is indicated at b in the drawing, this coating being very thin, merely sufficient to provide a continuous surface upon one side of the strip. The other side of the paper strip presents the normal finish of the paper, and has firmly bonded thereto a thin coating a of gutta-percha, covering the entire face of the strip and presenting a smooth continuous surface, having a general granular character resulting from the manner of applying

same to the paper.

It is obvious that in the handling of the completed strip of facing material the gutta-percha facing g will be incapable of stretch or distortion because of its firm adherence to the non-elastic paper strip a. As compared with gutta-percha tissue, the quantity of gutta-percha required to secure the desired bonding action, when assembling the facing disk in a cap, is somewhat reduced.

In cutting disks from a strip of the material, there is no tendency toward mutilation of the gutta-percha by reason of possible drag in the cutting die, and each disk, as delivered from the die to within a cap, will present a continuous uninterrupted gutta-percha surface upon the disk, so as to ensure, by the subsequent application of heat and pressure, a bond between the disk and the cap co-extensive in area with the disk.

Since, in applying the gutta-percha to the paper, the conditions are such as to completely fill all surface pores, it is obvious that during the bonding action, in the facing machine there is no tendency of the gutta-percha, during and after fusing, leaving exposed, minute openings at any point of the surface of the paper.

By reason of the thinness of the gutta-percha facing g, there is no tendency toward the expression of any of the gutta-percha from between the facing disk and the portion of the cap to which it is applied.

The possibility of securing a clean cut by the dies for forming the disks, both as to the paper and as to the gutta-percha facing g, ensures an effective bond entirely about the edge of the disk, presenting a continuous barrier of non-absorptive, gas impervious and acid resisting material at the space between the disk and the cap which will effectively pre-

vent the seepage of gas or fluids in a bottle between the disk and the portion of the cap to which it is applied.

In Fig. 1 of the drawings, I have illustrated the method of making the strip material of my invention. In the practice of this method, I use an ordinary mill with its heated rollers d and e. Operative in relation to the lower roller e is a backing roller f. A strip of the paper or other material a is drawn between the rollers e and f by means of the feed rollers g, by which it is passed to a re-wind mechanism indicated at h.

The method contemplates the feeding of the strip a between a backing roller f, and between one of the heated rolls of a gutta-percha mill e, thus applying a thin coating of gutta-percha while hot, to one surface only of the paper strip a, the gutta-percha hardening from its exposure to the surrounding temperature before engagement by the feed rollers g.

In feeding the strip a in the manner above described, the varnish surface thereof is presented downwardly, this surface having been applied to the paper prior to the feeding of the strip in the mill. In this manner a very thin coating of gutta-percha may be applied to one face of the strip a, to which it will firmly adhere while said strip is passing between the rollers e and f.

The thickness of the surface coating may be controlled by adjustment of the rollers d and e, and also by adjustment of the roller f in relation to the latter. In this manner, the strip a will have applied thereto a surfacing of gutta-percha which will be evenly distributed throughout the entire surface of the strip, and will present a substantially smooth exterior surface, notwithstanding surface irregularities in the paper itself. The smooth polished surface c will avoid any

possibility of a surface stratum c adhering to the adjoining stratum b after the strip is re-wound and while it is being unwound in the disk applying machine, since the gutta-percha will not become tacky under normal factory temperatures.

It is preferable to apply the gutta-percha in the manner above described, to wide strips of paper which are cut into narrower strips of the desired width for use with bottle caps of different diameters.

The method described has been found to be applicable to the coating of paper strips with gutta-percha, and it is also applicable but in coating foil it is desirable to provide, prepare, as by the application of a coating, ~~it being extremely doubtful if it could be advantageously used~~ to coat metal foil, ~~without a previous preparation~~ of one surface of the foil to receive the gutta-percha and permit it to adhere thereto with sufficient strength to permit a continuing application of gutta-percha to a strip as required by the method of my invention.

Facing material embodying the invention possesses the advantages that a substantially uniform and complete distribution of the gutta-percha throughout each disk cut from a strip, is assured. The additional labor of associating a strip of gutta-percha tissue and a strip of facing material is avoided, and higher speeds may be attained in the facing disk applying machine. By the method of applying fused gutta-percha to a facing strip, there is considerable saving, not only by the reduction in the amount of gutta-percha required, as compared with the use of gutta-percha tissue, but the preparation of the strips for use in the disk applying machines is very much reduced, and a more uniform quality in the bond between the disks and the caps is also assured.

It is preferable for the bottling of many liquids to employ facing material composed of paper of the general character herein described, as compared

with the use of metal foils.

Having described the invention, what I claim as new and desire to have protected by Letters Patent, is:-

1:- Material for facing bottle caps consisting of a facing strip of non-absorbent, gas impervious and acid resisting material, having bonded thereto, throughout one face thereof, a thin surfacing of gutta-percha.

2:- Material for facing bottle caps consisting of a paper strip, having applied to one surface thereof a surface of non-absorbent, gas impervious and acid resisting material, and having bonded thereto, throughout the other surface thereof, a thin surfacing of gutta-percha.

3:- Material for facing bottle caps consisting of a paper strip, having applied to one surface thereof a surface coating of varnish consisting of resin, China-wood oil, a drier and a plasticizer, whereby said surface of the paper is made non-absorbent, gas impervious and acid resisting, and having bonded thereto, throughout the other surface thereof, a thin surfacing of gutta-percha.

4:- The herein described method of making material for facing bottle caps consisting of applying a thin stratum of fused gutta-percha to one surface of a continuous strip of fibrous facing material, while subjecting said material and said gutta-percha to sufficient pressure to cause the gutta-percha to conform with, and adhere to, the surface of said material.

5:- The herein described method of making material for facing bottle caps consisting of moving a continuous strip of paper across a cold backing roll in operative relation to a heated roll of a gutta-percha mill, and applying a thin coating of fused gutta-percha to said strip by subjecting said

strip and said gutta-percha to sufficient pressure to cause the gutta-percha to conform with, and adhere to, the surface of said material.

In witness whereof I have hereunto affixed my signature ~~in the presence of two subscribing witnesses~~, this [illegible] of December 1939.

Alva W. Watts [illegible]

Hon. Commissioner of Patents,
Washington, D. C.

Sir:

We hereby authorize and request entry of the following amendments in the above entitled application.

IN THE CLAIMS

Cancel claims 4 and 5.

~~Add the following claims:~~

Add 2 As a new article of manufacture, bottle cap liner material in strip form comprising paper having a high gloss and having a coating of varnish on one surface of the paper and bonded to the other surface thereof a coating of gutta percha.

Add 3 As a new article of manufacture, paper having a high gloss and having a coating of varnish on one surface of the paper and a coating of gutta percha on the other surface thereof

REMARKS

Applicant has complied with the requirement for division, and herewith presents two article claims somewhat similar to the article claims originally filed.

In view of the prompt amendment, in response to the requirement for division, this application is thought

to be entitled to immediate action on the merits in accordance with the Order of the Commissioner 2670:

> "Where the first action by the Examiner upon an application is limited to a requirement for division, the application will thereafter be given preference in the order of examination over other applications previously acted upon until it has received one action upon the merits, provided the applicant makes prompt response to the Examiner's requirement for division". (287 O. G. 409)

In order to expedite the prosecution of the case, applicant presents, with this amendment, an affidavit under Rule 75, antedating the patent to Lange #1,758,61 May 13, 1930. It is thought that an interference with this patent is unnecessary for the reason that, in a companion apolication, (Ser. No. 360,895, filed May 6, 1929) the Examiner has held that the Lange patent is limited to gutta percha applied in solution form. In that case, the Examiner said:

> "Secondly, the claim recites a "coating of gutta percha". Referring to the specification of the patent it is found that the gutta percha is applied in the form of a solution, the solvent being suitably driven off to leave a thin film of gutta percha. Patentee specifically refers to the objections and disadvantages resulting from the use of gutta percha in thin sheet form (page 3, lines 41 to 56) and seeks to escape these objectionable results by applying the adhesive in liquid form, which is expressed in the claim by the word "coating". Applicant does not apply the gutta percha in liquid form as a coating but rather in thin sheet form. Consequently, this claim does not read upon applicant's disclosure inasmuch as he has disclosed no application of the adhesive in liquid form to provide a coating".

The above ruling of the Examiner, with reference to the Lange patent and also with reference to the disclosure of the applicant, fully applies to the present case. Admittedly the applicant does not disclose the application of gutta percha in solution, i. e. with a solvent. In

the present case, plastic gutta percha is rolled in a thin layer upon one surface of the paper to provide a stratum or surfacing. Whether the Examiner is right in his interpretation of the Lange claim, is a matter which seems immaterial at this time, since applicant is not presenting claims limited to a solution or precipitated coating, although obviously presenting claims which dominate this specific form of coating.

Of course, the terms "stratum" and "surfacing", as used in the specification, are intended to cover the gutta percha in the final product without reference to its form at the time it is applied. The form of the gutta percha at the time it is applied relates to the method of manufacture, and this is claimed by the application of a divisional case, which is being filed.

The term "bonded" refers to the union of the gutta percha with the paper.

The applicant was the first to apply to one surface of paper of the character defined, a varnish coating or surfacing and, to the opposite surface, a surfacing or stratum of gutta percha which adheres to the paper.

The two new claims presented by this amendment are substantially identical. Claim 6 has been drafted by applicant as a proper definition of his invention, and is thought to be allowable without an interference with the Lange patent for the reasons stated by the Examiner. However, applicant is defining the same invention, although by slightly different terms, in claim 7, which contains the precise language of the Lange claim. He is doing this, so that if the Examiner feels disposed to modify his position, he may do so and

promptly declare an interference between this application or applicant's copending application and the Lange patent.

Respectfully,

Cushman, Bryant & Duby
Attorneys.

APPLICATION DIV. OCT 27 30

IN THE UNITED STATES PATENT OFFICE

Albin H. Warth,

METHOD FOR FACING BOTTLE CAPS
& METHOD OF MAKING SAME,

Filed Dec. 17, 1929,

Serial No. 414,614, Div. 50.

A F F I D A V I T

CITY OF BALTIMORE)
:SS.
STATE OF MARYLAND)

GEORGE GOEBEL, being duly sworn, deposes and says:

I am an engineer in the employ of Crown Cork & Seal Company, Inc., manufacturers of bottle caps, crown corks, etc., and having a place of business in the City of Baltimore, and State of Maryland.

I am familiar with the invention disclosed in the above entitled application of Albin H. Warth, and have read the accompanying amendment, as well as the claims standing in the application.

The said Albin H. Warth provided for the Crown Cork & Seal Company, Inc., prior to July 3, 1929, high gloss or express paper having a varnish coating on one surface and an adhering stratum or surfacing of gutta percha on the other surface. This paper was produced in both disc form and sheet or strip form, and was employed as a liner in caps prior to July 3, 1929. The gutta percha surfacing was used to unite the material to the cork insert within the cap and the varnished surface of the paper was left exposed.

Further Deponent sayeth not.

George Gaebel

Subscribed and sworn to before me, a Notary Public, this 21st day of October, 1930.

Albin H. Warth,

METHOD FOR FACING BOTTLE CAPS
& METHOD OF MAKING SAME,

Filed Dec. 17, 1929,

Serial No. 414,614. Div. 50.

AFFIDAVIT UNDER RULE 75

CITY OF BALTIMORE)
:SS.
STATE OF MARYLAND)

ALBIN H. WARTH, being first duly sworn, deposes and says:

I am the applicant identified in the above entitled application, and have read the accompanying amendment.

Prior to July 3, 1929, I made and used in bottle caps liner material in both disc and sheet or strip form, the material comprising express paper which has a high gloss, this paper being provided on one surface with a coating of varnish and on the other surface with a stratum or surfacing of gutta percha in adhesive union with the paper. This material was used under my supervision by the Crown Cork & Seal Company, Inc., of Baltimore, Maryland, in the manufacture of bottle caps prior to July 3, 1929. It was applied to the caps by utilizing the gutta percha stratum or surfacing to unite the paper to the cork liner or insert in the cap. The varnish surface of the paper was left exposed.

I do not know and do not believe that the invention has been in public use or on sale in this country, or patented or described in a printed publication in this

or any foreign country for more than two years prior to my above entitled application, and I have never abandoned the invention.

This affidavit is made for the purpose of antedating the patent to Lange, No. 1,758,610, granted May 13, 1930.

Further Deponent sayeth not.

Albin H. Waitz

Applicant: Albin H. Warth

Ser. No. 414,614
Filed Dec. 17, 1929
For Material for Facing Bottle Caps and Methods of Making Same

Cushman, Bryant & Darby,
Washington Loan & Trust Bldg.,
Washington, D. C.

The case, above referred to, is forwarded to the Examiner of Interferences because it is adjudged to interfere with others, hereafter specified. The question of priority will be determined in conformity with the Rules. The interference will be identified as No. 60878 On or before JAN 19 1931

the statement demanded by rule 110 must be sealed up and filed with the subject of invention, and name of party filing it, indorsed on the envelope. The subject-matter involved in the interference is

Count 1. As a new article of manufacture, paper having a high gloss and having a coating of varnish on one surface of the paper and a coating of gutta percha on the other surface thereof.

This interference involves your application above identified and a patent No. 1,758,610 for Adhesive Backing granted to Louvern G. Lange May 13, 1930 whose address is 39 High St., Passaic, New Jersey, and whose attorneys of record are Pennie, Davis, Marvin and Edmonds of 165 Broadway, New York, N. Y., the application for said patent having been filed July 3, 1929, Serial No. 375,883.

The relation of the counts of the interference to the claims of the respective parties is as follows:-

Count	Warth	Lange
1	7	1

After termination of the interference this application will be held for restriction and revision under Rule 96.

Claims 1, 2, 3 and 6 will be held subject to rejection as unpatentable over the issue in the event of an award of priority adverse to applicant.

Ed Blake
Examiner.

Sir:

We hereby authorize and request entry of the following amendments in the above entitled application.

IN THE SPECIFICATION

Page 2

Line 8 cancel the paragraph beginning "In preparing etc.," and ending in line ~~14~~ 21.

Page 4

Line 12 correct the spelling of "globules".

Page 6

Line 21 cancel "leaf".

Page 9

Lines 10 and 11 cancel "it being extremely doubtful if it could be advantageously used" and substitute --and it is also applicable--.

Line 12 cancel "without a previous preparation of" and substitute --, but in coating foil it is desirable to previously prepare, as by the application of a coating,--.

Next to last line after "preferable" insert --for the bottling of many liquids--.

1097

1341

IN THE CLAIMS

Cancel claims 1 and 2.

Claim 3

Line 1 change "Material" to --material--, and before "material" insert --As a new article of manufacture,--.

Line 5 correct the spelling of "impervious".

Claim 6

Line 2 after "material" insert --in strip form--.

Add the following claims:

8. As a new article of manufacture, bottle cap spotting material in strip form comprising express paper having a coating of varnish on one surface and bonded to the other surface thereof a coating of gutta percha.

9. As a new article of manufacture, bottle cap spotting material in strip form comprising bleached kraft paper having a coating of varnish on one surface and bonded to the other surface thereof a coating of gutta percha.

(B)

10. As a new article of manufacture, laminated bottle cap spotting material in strip form comprising hard, tough paper having relatively low absorptive properties, a coating of resistant varnish on one surface of the paper and bonded to the other surface a coating of heat fusible, waterproof and flexible adhesive.

11. As a new article of manufacture, laminated bottle cap spotting material in strip form comprising hard, tough paper having relatively low absorptive properties, a coating of resistant varnish on one surface of the paper and bonded to the other surface a coating of gutta percha.

12. As a new article of manufacture, highly flexible material in sheet or strip form adapted for the spotting of cushion discs of crown caps with center spots of less diameter than the disc diameter by the mere application of heat and pressure consisting of a continuous layer of material selected from a group consisting of metallic foil and varnish coated tough paper having relatively low absorptive properties, said layer being coated on one side with an exposed continuous layer of waterproof, flexible, and acid resistant adhesive adherent to the foil and adapted to adhere to a cork disc, said adhesive being substantially non-tacky at room temperature but fusible upon the application of heat and substantially impervious to moisture whereby spots may be punched from the strip and united to the cushion discs of caps by the mere application of heat and pressure.

REMARKS

The interference (60,878) in which this application was involved having terminated favorably to the applicant, it is requested that this case be considered, and it is thought that the same is in condition for allowance.

The new claims with the exception of claim 12 are specific to coated paper. Claim 12 is generic to the subject matter of this application and of the co nding case, Serial No. 494,201, filed November 7, 1930.

Respectfully,

Serial No. 414,614

DEPARTMENT OF COMMERCE
UNITED STATES PATENT OFFICE
WASHINGTON February THD, 1933

Albin H. Warth, Assor.,

Your APPLICATION for a patent for an IMPROVEMENT in Material for Facing Bottle Caps and Method of Making Same

filed Dec.17,1929 has been examined and ALLOWED with 8 claims.

The final fee, THIRTY DOLLARS, WITH $1 ADDITIONAL FOR EACH CLAIM ALLOWED IN EXCESS OF 20, must be paid not later than SIX MONTHS from the date of this present notice of allowance. If the final fee be not paid within that period, the patent will be withheld, but the application may be renewed within one year after the date of the original notice with a renewal fee of $30 and $1 additional for each claim in excess of 20.

The office delivers patents upon the day of their date, on which date their term begins to run. The preparation of the patent for final signing and sealing will require about four weeks, and such work will not be begun until after payment of the necessary final fee.

When the final fee is paid, there should also be sent, DISTINCTLY AND PLAINLY WRITTEN, the name of the INVENTOR, TITLE OF THE INVENTION, AND SERIAL NUMBER AS ABOVE GIVEN, DATE OF ALLOWANCE (which is the date of this circular), DATE OF FILING, and, if assigned, the NAMES OF THE ASSIGNEES.

If it is desired to have the patent issue to an ASSIGNEE OR ASSIGNEES, an assignment containing a REQUEST to that effect, together with the FEE for recording the same, must be filed in this office on or before the date of payment of the final fee.

After issue of the patent, uncertified copies of the drawings and specifications may be purchased at the price of TEN CENTS EACH. The money should accompany the order. Postage stamps will not be received.

The final fee will NOT be received from other than the applicant, his assignee or attorney, or a party in interest as shown by the records of the Patent Office.

NOTICE.—WHEN THE NUMBER OF CLAIMS ALLOWED IS IN EXCESS OF 20, NO SUM LESS THAN $30 PLUS $1 ADDITIONAL FOR EACH CLAIM IN EXCESS OF TWENTY CAN BE ACCEPTED AS THE FINAL FEE.

Respectfully,

Thomas E. Robertson
Commissioner of Patents.

Cushman, Bryant, Darby & Cushman,
American Security Bldg.,
Washington, D. C.

IN REMITTING THE FINAL FEE GIVE THE SERIAL NUMBER AT THE HEAD OF THIS NOTICE.

UNCERTIFIED CHECKS WILL NOT BE ACCEPTED.

AMENDMENT UNDER RULE 78

February 3, 1933.

Hon. Commissioner of Patents,
Washington, D. C.

Sir:

We hereby authorize and request the entry of the following amendment under Rule 78, without withdrawing the application from issue:

IN THE SPECIFICATION

Page 1

Line 12, after the period insert the following paragraph:

C1 "This application is a continuation-in-part of my copending application Serial No. 494,201, filed November 7, 1930, the latter being a division of my application Serial No. 159,743, filed January 7, 1927, and now Patent No. 1,788,260, granted January 6, 1931."

Line 19, after the period insert the following: "Such a method is illustrated and described in my copending application Serial No. 492,546, filed October 31, 1930, as a division of my copending application Serial No. 360,895, filed May 5, 1929. As will be understood, this method of procedure is utilized in the production of caps of the "center spot" type, i.e. which are pro-

vided with a facing or "center spot" of less diameter than the cap or cushion disc within the cap. It is to the production of material for the manufacture of caps of this "center spot", that the present invention more particularly relates, although in its broader aspects it is useful in the manufacture of caps having facings other than "center spots". A further illustration of a cap of the "center spot" type is to be found in the patent to McManus 1,330,066, granted May 4, 1920.

Same line (19), after "such" insert --center spots" or--.

Line 23, after the period insert the following: --As will be understood, facings of the "center spot" type are applied within the formed cap to the cushion liner and this method of manufacture presents problems quite distinct from the manufacture of caps having facings coextensive with the cushion liner, since facings coextensive with the cushion liner are ordinarily produced by adhesively uniting superimposed facing material and cushion liner material, both in sheet form, thereafter simply punching laminated discs of facing material and cushion material from the laminated sheet.--

Page 7

Line 15, after the period insert the following: --The method involved in utilizing my invention need not be more fully described herein, since it is more fully disclosed and covered in my issued patent 1,788,260, granted January 6, 1931.--

IN THE CLAIMS

Add the following claim:

1106

1350

?

#134 As a new article of manufacture, highly flexible material in sheet or strip form for the spotting of cushion discs of caps with center spots of less diameter than the disc diameter consisting of a continuous layer of metallic foil coated on one side with an exposed continuous layer of waterproof, flexible, and acid resistant adhesive adherent to the foil and adapted to adhere to a cork disc, said adhesive being substantially non-tacky at room temperature but fusible upon the application of heat and substantially impervious to moisture whereby spots may be punched from the strip and united to the cushion discs of caps by the mere application of heat and pressure.#

(C3)

(Dig)

REMARKS

The foregoing claim is submitted for the purpose of transferring from the copending allowed application Serial No. 494,201, the first of the two (2) claims allowed therein. The single claim transferred, and numbered 13 above, is a species claim subordinate to allowed claim 12 in this application. As stated, this application is a continuation-in-part of applicant's patent No. 1,788,260, granted January 6, 1931, and such part includes the subject matter of claims 12 and 13 herein.

The specification has been amplified somewhat in a purely descriptive manner to indicate the particular products or field of this invention and reference has been made to applicant's copending case (allowed) Serial No. 429,546, as illustrating the center spot type of cap to which this invention relates in its more specific aspects.

UNITED STATES PATENT OFFICE

ALBIN H. WARTH, OF BALTIMORE, MARYLAND, ASSIGNOR TO CROWN CORK & SEAL COMPANY, INC., OF NEW YORK, N. Y., A CORPORATION OF NEW YORK

MATERIAL FOR FACING BOTTLE CAPS AND METHOD OF MAKING SAME

Application filed December 17, 1929. Serial No. 414,614.

My invention relates to material for facing bottle caps and method of making same, and more particularly to strip material having applied to one face thereof a coating of gutta-percha.

This application is a continuation-in-part of my copending application Serial No. 494,201, filed November 7, 1930, the latter being a division of my application Serial No. 159,743, filed January 7, 1927, and now Patent No. 1,788,260, granted January 6, 1931.

Heretofore, facing material for bottle caps has been secured in position within the caps by means of gutta-percha tissue. In forming the facing disks and applying them to the caps, the practice has been to cut disks from superimposed strips of facing material and gutta-percha tissue, deposit the disks in the cap and apply heat for the purpose of fusing the gutta-percha tissue. Such a method is illustrated and described in my copending application Serial No. 492,546, filed October 31, 1930, as a division of my copending application Serial No. 360,895, filed May 5, 1929. As will be understood, this method of procedure is utilized in the production of caps of the "center spot" type, i. e. which are provided with a facing or "center spot" of less diameter than the cap or cushion disc within the cap. It is to the production of material for the manufacture of caps of this "center spot", that the present invention more particularly relates, although in its broader aspects it is useful in the manufacture of caps having facings other than "center spots". A further illustration of a cap of the "center spot" type is to be found in the patent to McManus 1,339,066, granted May 4, 1920. One difficulty in thus applying such "center spots" or disks to caps has arisen from the use of superimposed unconnected strips of facing material and of gutta-percha, the two strips being simultaneously fed from the same roll in relation to the punch of the face applying machine. As will be understood, facings of the "center spot" type are applied within the formed cap to the cushion liner and this method of manufacture presents problems quite distinct from the manufacture of caps having facings coextensive with the cushion liner, since facings coextensive with the cushion liner are ordinarily produced by adhesively uniting superimposed facing material and cushion liner material, both in sheet form, thereafter simply punching laminated discs of facing material and cushion material from the laminated sheet.

With this condition, there is not only difficulty in feeding the strip, but in cutting the gutta-percha with a clean sharp edge so as to ensure the binding stratum of gutta-percha being co-extensive in area with the facing disk. The gutta-percha binding stratum in such disks is intended not only to act as a cement, but also as a non-absorbent, gas impervious medium for avoiding possibility of the contents of a bottle getting between the facing disk and the material of the cap, either the metal shell itself or a cushion disk of cork or composition cork.

Furthermore, when thus using superimposed strips of the facing material and of gutta-percha tissue, it was essential, during the application of the disk to the cap, to bond the gutta-percha to both the material of the cap and the facing material.

It is desirable, in the use of facing disks of the character above referred to, that the gutta-percha stratum be as thin as possible, and yet be continuous throughout the entire area of the facing disk, and particularly that it be uninterrupted about the edge of this disk, since at this point the disk should be firmly bonded so as to effectively seal the joint about the edge of the facing disk. When cutting and applying the disks of paper and gutta-percha, there is no means of ascertaining whether the desired conditions are present in the completed cap. Consequently, there is always likelihood of imperfectly faced caps being produced.

With the above conditions in mind, I have provided material, in strip form, for facing bottle caps, in which one surface of the strip is provided with a firmly adherent, continuous thin facing of gutta-percha, thus avoiding all necessity for assembling strips of facing material and of gutta-percha tissue preparatory to their use in the bottle cap facing machine, and all of the disadvantages growing out of this practice.

Page Tightly Bound

In the strip material of my invention, a very thin stratum of gutta-percha is evenly distributed upon one face of a strip of facing material. The gutta-percha is not only firmly bonded to this material, but is forced into the surface grain thereof, and has a smooth surface finish of sufficient thickness to form the desired firm bond between a disk cut from the strip and the material of the cap to which such disk is cemented.

The manner of applying the gutta-percha to the facing strip is such as to ensure substantial uniformity in the condition of the gutta-percha throughout the strip by reason of the fact that those impurities or imperfections resulting from the working of gutta-percha in a mill will develop only along the edges of the facing material, where they may either be removed by trimming wide strips of the material, or will come within the wastage of narrow strips when cutting disks from such strips.

Furthermore, gutta-percha tissue must be of a thickness to have sufficient inherent strength to permit of its being stripped from a roll in a mill for working same, and to admit of its being cut to the desired width and to be handled in the re-winding and the disk applying, machines, and during the process of its production it has more or less of a longitudinally extending grain as distinguished from its normal granular formation.

In applying the gutta-percha to the fibrous or metallic facing material in accordance with my invention, the thickness of the gutta-percha is determined solely by that required to secure the desired intermediate stratum of the gutta-percha in the finished cap.

In the application of heat, when bonding the facing material to the cap, when utilizing gutta-percha tissue, a tendency of the gutta-percha is to break up into slightly isolated, small globules, thus interrupting the continuity of the bonding stratum. Whether this is due to irregularities in the surface of the facing strip, or to a shrinkage of the gutta-percha tissue when fused, I have been unable to determine. In the strip of my invention, however, the gutta-percha is thoroughly distributed throughout one face of the facing material, and the above conditions do not develop in the subsequent handling of the strips.

So far as the method of producing the strip is concerned, it is such that the effective distribution of the gutta-percha throughout the entire area of the facing material is assured, and this condition cannot be disturbed as a result of the cutting of disks from this material when in strip form. Furthermore, the gutta-percha surface may be thoroughly inspected while producing the strip material, so that any imperfect product may be discarded before it reaches the disk applying machine.

It is desired to note that the surface of the strip to which the gutta-percha is not applied is always a highly polished surface, whether it be a varnish fibrous material such as paper, or a metal foil, so that the gutta-percha surface will not adhere thereto. By applying the gutta-percha directly to the surface of the paper and firmly bonding it there is no likelihood of difficulties arising as a result of the separation of the gutta-percha from the facing strip during the unwinding operation, either as a result of slight adherence, from suction or otherwise, such as frequently occurs when using the superimposed strips of the facing material and of gutta-percha tissue.

The invention consists primarily in material for facing bottle caps consisting of a facing strip of non-absorbent, gas impervious and acid resisting material, having bonded thereto, throughout one face thereof, a thin surfacing of gutta-percha; and in such other novel characteristics, and in the novel steps and practices of producing same, all as hereinafter set forth and described, and more particularly pointed out in the claims hereto appended.

Referring to the drawing,

Fig. 1 is a diagrammatic showing of the method of producing the facing material of the invention;

Fig. 2 is a longitudinal view, partly in cross section, of a fragmentary portion of said material; and

Fig. 3 is a face view thereof with a portion of the facing strip broken away.

Like letters refer to like parts throughout the several views.

In the accompanying drawing, the thickness dimensions are all greatly exaggerated. the thickness of the facing strip being less than five thousandths of an inch, and that of the gutta-percha surfacing, less than two thousandths of an inch.

In the embodiment of the invention shown in the drawing, the facing strip is composed of what is known as express paper which is a hard, tough paper having little absorptive properties. The properties inherent to the paper, however, are such, if properly finished, as to adapt it for use as facing material for bottle caps, although it is extremely difficult to satisfactorily cement such paper to the metal shell or cork cushion of such a closure.

In order to impart to one surface of the paper only the desired properties which will result in this strip presenting toward the contents of a bottle, a surface which is non-absorbent, gas impervious and acid resisting, I give a finish to this surface consisting of a coating of a varnish having the desired properties, and which includes therein resin.

China-wood oil, a drier and a plasticizer. This surface finish, in addition to having the properties above described, will also be sufficiently flexible to avoid the formation of cracks, or impart to the paper strip as a whole, a degree of brittleness which might result in the formation of such cracks or seams in the paper as would destroy the surface finish and permit the contents of the bottle to attack the body of the paper.

While express paper is a water finish paper, other similar papers may be used such as sulfite paper or bleached kraft paper.

The varnish finish coating above referred to is indicated at *b* in the drawing, this coating being very thin, merely sufficient to provide a continuous surface upon one side of the strip. The other side of the paper strip presents the normal finish of the paper, and has firmly bonded thereto a thin coating *c* of gutta-percha, covering the entire face of the strip and presenting a smooth continuous surface, having a general granular character resulting from the manner of applying same to the paper.

It is obvious that in the handling of the completed strip of facing material the gutta-percha facing *c* will be incapable of stretch or distortion because of its firm adherence to the non-elastic paper strip *a*. As compared with gutta-percha tissue, the quantity of gutta-percha required to secure the desired bonding action, when assembling the facing disk in a cap, is somewhat reduced.

In cutting disks from a strip of the material, there is no tendency toward mutilation of the gutta-percha by reason of possible drag in the cutting die, and each disk, as delivered from the die to within a cap, will present a continuous uninterrupted gutta-percha surface upon the disk, so as to ensure, by the subsequent application of heat and pressure, a bond between the disk and the cap co-extensive in area with the disk. The method involved in utilizing my invention need not be more fully described herein, since it is more fully disclosed and covered in my issued Patent 1,788,260, granted January 6, 1931.

Since, in applying the gutta-percha to the paper, the condition are such as to completely fill all surface pores, it is obvious that during the bonding action, in the facing machine there is no tendency of the gutta-percha, during and after fusing, leaving exposed, minute openings at any point of the surface of the paper.

By reason of the thinness of the gutta-percha facing *c*, there is no tendency toward the expression of any of the gutta-percha from between the facing disk and the portion of the cap to which it is applied.

The possibility of securing a clean cut by the dies for forming the disks, both as to the paper and as to the gutta-percha facing *c*, ensures an effective bond entirely about the edge of the disk, presenting a continuous barrier of non-absorptive, gas impervious and acid resisting material at the space between the disk and the cap which will effectively prevent the seepage of gas or fluids in a bottle between the disk and the portion of the cap to which it is applied.

In Fig. 1 of the drawing, I have illustrated the method of making the strip material of my invention. In the practice of this method, I use an ordinary mill with its heated rollers *d* and *e*. Operative in relation to the lower roller *e* is a backing roller *f*. A strip of the paper or other material *a* is drawn between the rollers *e* and *f* by means of the feed rollers *g*, by which it is passed to a re-wind mechanism indicated at *h*.

The method contemplates the feeding of the strip *a* between a backing roller *f*, and between one of the heated rolls of a gutta-percha mill *e*, thus applying a thin coating of gutta-percha while hot, to one surface only of the paper strip *a*, the gutta-percha hardening from its exposure to the surrounding temperature before engagement by the feed rollers *g*.

In feeding the strip *a* in the manner above described, the varnish surface thereof is presented downwardly, this surface having been applied to the paper prior to the feeding of the strip in the mill. In this manner a very thin coating of gutta-percha may be applied to one face of the strip *a*, to which it will firmly adhere while said strip is passing between the rollers *e* and *f*.

The thickness of the surface coating may be controlled by adjustment of the rollers *d* and *e*, and also by adjustment of the roller *f* in relation to the latter. In this manner, the strip *a* will have applied thereto a surfacing of gutta-percha which will be evenly distributed throughout the entire surface of the strip, and will present a substantially smooth exterior surface, notwithstanding surface irregularities in the paper itself. The smooth polished surface *c* will avoid any possibility of a surface stratum *c* adhering to the adjoining stratum *b* after the strip is re-wound and while it is being unwound in the disk applying machine, since the gutta-percha will not become tacky under normal factory temperatures.

It is preferable to apply the gutta-percha in the manner above described, to wide strips of paper which are cut into narrower strips of the desired width for use with bottle caps of different diameters.

The method described has been found to be applicable to the coating of paper strips with gutta-percha, and it is also applicable to coat metal foil, but in coating foil it is desirable to previously prepare, as by the application of a coating, one surface of the foil to receive the gutta-percha and permit it to adhere

1116

thereto with sufficient strength to permit a continuing application of gutta-percha to a strip as required by the method of my invention.

Facing material embodying the invention possesses the advantages that a substantially uniform and complete distribution of the gutta-percha throughout each disk cut from a strip, is assured. The additional labor of associating a strip of gutta-percha tissue and a strip of facing material is avoided, and higher speeds may be attained in the facing disk applying machine. By the method of applying fused gutta-percha to a facing strip, there is considerable saving, not only by the reduction in the amount of gutta-percha required, as compared with the use of gutta-percha tissue, but the preparation of the strips for use in the disk applying machines is very much reduced, and a more uniform quality in the bond between the disks and the caps is also assured.

It is preferable for the bottling of many liquids to employ facing material composed of paper of the general character herein described, as compared with the use of metal foils.

Having described the invention, what I claim as new and desire to have protected by Letters Patent, is:—

1. As a new article of manufacture, material for facing bottle caps consisting of a paper strip, having applied to one surface thereof a surface coating of varnish consisting of resin, China-wood oil, a drier and a plasticizer, whereby said surface of the paper is made non-absorbent, gas impervious and acid resisting, and having bonded thereto, throughout the other surface thereof, a thin surfacing of gutta-percha.

2. As a new article of manufacture, bottle cap liner material in strip form comprising paper having a high gloss and having a coating of varnish on one surface of the paper and bonded to the other surface thereof a coating of gutta percha.

3. As a new article of manufacture, paper having a high gloss and having a coating of varnish on one surface of the paper and a coating of gutta percha on the other surface thereof.

4. As a new article of manufacture, bottle cap spotting material in strip form comprising express paper having a coating of varnish on one surface and bonded to the other surface thereof a coating of gutta percha.

5. As a new article of manufacture, bottle cap spotting material in strip form comprising bleached kraft paper having a coating of varnish on one surface and bonded to the other surface thereof a coating of gutta percha.

6. As a new article of manufacture, laminated bottle cap spotting material in strip form comprising hard, tough paper having relatively low absorptive properties, a coating of resistant varnish on one surface of the paper and bonded to the other surface a coating of heat fusible, waterproof and flexible adhesive.

7. As a new article of manufacture, laminated bottle cap spotting material in strip form comprising hard, tough paper having relatively low absorptive properties, a coating of resistant varnish on one surface of the paper and bonded to the other surface a coating of gutta percha.

8. As a new article of manufacture, highly flexible material in sheet or strip form adapted for the spotting of cushion discs of crown caps with center spots of less diameter than the disc diameter by the mere application of heat and pressure consisting of a continuous layer of material selected from a group consisting of metallic foil and varnish coated tough paper having relatively low absorptive properties, said layer being coated on one side with an exposed continuous layer of waterproof, flexible, and acid resistant adhesive adherent to the foil and adapted to adhere to a cork disc, said adhesive being substantially nontacky at room temperature but fusible upon the application of heat and substantially impervious to moisture whereby spots may be punched from the strip and united to the cushion discs of caps by the mere application of heat and pressure.

9. As a new article of manufacture, highly flexible material in sheet or strip form for the spotting of cushion discs of caps with center spots of less diameter than the disc diameter consisting of a continuous layer of metallic foil coated on one side with an exposed continuous layer of waterproof, flexible, and acid resistant adhesive adherent to the foil and adapted to adhere to a cork disc, said adhesive being substantially non-tacky at room temperature but fusible upon the application of heat and substantially impervious to moisture whereby spots may be punched from the strip and united to the cushion discs of caps by the mere application of heat and pressure.

In witness whereof I have hereunto affixed my signature, this 11th day of December 1929.

ALBIN H. WARTH.

C. E. McMANUS.

FACING MATERIAL FOR CORK OR OTHER DISKS FOR BOTTLE CAPS.

APPLICATION FILED MAY 9, 1916.

1,213,926. Patented Jan. 30, 1917.

Attest:

Chas. E. McManus Inventor:
by Frank P. Wentworth
his Atty.

UNITED STATES PATENT OFFICE.

CHARLES E. McMANUS, OF NEW YORK, N. Y.

FACING MATERIAL FOR CORK OR OTHER DISKS FOR BOTTLE-CAPS.

1,213,926. Specification of Letters Patent. Patented Jan. 30, 1917.

Application filed May 9, 1916. Serial No. 96,304.

To all whom it may concern:

Be it known that I, CHARLES E. McMANUS, a citizen of the United States, residing at the borough of Manhattan, city, county, and State of New York, have invented certain new and useful improvements in Facing Material for Cork or other Disks for Bottle-Caps, of which the following is a specification, reference being had therein to the accompanying drawings, which form a part thereof.

My invention relates to facing material for cork or other disks for bottle caps and more particularly to material of this kind wherein the face presented toward the contents of the bottle is a metal foil.

Heretofore cork or other disks for bottle caps have had the central portion thereof provided with a facing disk to protect the cork or other disk from the action of the contents of the bottle, and prevent contamination of the contents of the bottle, through contact with said cork or other disk. Various types of facing disks have been used, and have been applied to the cork or other disks, in different manners.

It has been attempted to use metal foil disks, but such have proven impracticable for the reason that it has been found extremely difficult to provide a stable bond between the cork or other disk and the metal foil disk, such being of vital importance to a disk faced with metal foil owing to the tendency of the agitators in the hopper of the bottling machine to separate the foil from the cork or other disk, or to raise the edge thereof therefrom. It has been proposed to slot the cork or other disk and form a cup of the metal foil and seat the rim of the cup in said slot, but this has not been found satisfactory, since it weakens the cork or other cushion and tends toward the formation of channels or leaks, through the slot. Furthermore, metal foil has practically no elasticity and low tensile strength and consequently in view of the difficulty of securing a permanent bond, coupled with the lack of elasticity of the foil preventing its yielding with the cork or other cushion disk, the difficulty of producing a workable metal faced cushion disk is practically insurmountable where metal alone is used for the facing material. In addition to the foregoing it is necessary to apply facing disks to the cork or other cushion disks so rapidly that they can be handled commercially only by machinery and metal foil alone cannot be fed satisfactorily in a machine and it is practically impossible to cut disks therefrom as required which will present a clean sharp edge.

By my invention, I am enabled to provide a facing material utilizing much thinner metal foil than is possible when using the metal foil alone, for the facing, the facing material being so constituted that when applied to the cork or other disk, it will be firmly bonded thereto and not liable to displacement through the contact therewith of the agitators in the hoppers of the capping machine. I secure these results by providing a flexible reinforcement or backing for the metal foil before it is applied to the cork or other disk, the metal foil being firmly bonded to this reinforcing backing and the backing being firmly bonded to the cork or other disk. This manner of forming the material permits the binding medium between the metal foil and the reinforcement or backing to firmly set before the facing disk is applied to the cork or other disk and permits greater uniformity in the distribution of the binding medium so as to avoid any weak spots which might tend toward the separation of the foil and its backing. This binding medium may also be selected with a view to its non-absorbent, gas impermeable property.

The material when ready for application to the cork or other disk is sufficiently rigid by reason of the binder between the metal foil and its backing, to insure a clean cutting of the disks, and the accurate feeding of the material in the machine. I also contemplate providing sufficient slack in the metal foil to permit that stretch incidental to the application of a cap to a bottle.

The invention consists in a facing material for cork or other disks for bottle caps, consisting of metal foil provided with a reinforcement or backing of fibrous material having one surface thereof gummed, and the other surface thereof firmly bonded to said metal foil by a stratum of a binding medium and in such other novel features of construction and combination of parts as are

hereinafter set forth and described and more particularly pointed out in the claims hereto appended.

In the accompanying drawings, I have shown a section of a strip of facing material embodying my invention.

In making the material of the invention, I preferably employ tin foil *a* which may be of a thickness no greater than .001 of an inch. This foil is backed or reinforced with fibrous material *b*, preferably paper, the foil being firmly bonded to the paper by a binding medium which is applied to the paper or other backing in a thin stratum *c* so as to insure uniformity of the bond between all parts of the adjoining surface of the foil and its backing. The paper or other backing has the surface thereof other than that to which the foil is to be or has been applied, gummed as indicated at *d* so as to permit the application of the facing to the cork or other disks by the application of a damping material to the face of the cork or other disk and thus facilitate the feeding and application of the casing material to the cork or other disk. By using a fibrous reinforcement or backing, the gum and the binding medium between the backing and the foil may readily penetrate this reinforcing backing material, to an extent to minimize any tendency of the facing disk to separate from the cork or other disk, or the foil to separate from said reinforcing or backing disk.

There are a number of binding mediums which may be used, such as sodium silicate, which will form a firm bond between the foil and the paper. Binding mediums of this type have the further advantage that they are insoluble when once set and form a continuous film which is substantially impermeable to gases. Since flexibility in the facing material is desirable, when I use sodium silicate, I mix with it a small percentage of glycerin in order to impart some flexibility to the stratum of binding material. I do not desire to limit myself to the use of sodium silicate, however, as there are many equivalent binding materials which will have the desired effect of insuring a permanent bond between a metal foil and a backing or reinforcement of paper or other fibrous material.

By applying the foil to the backing material and cutting the disks therefrom, I secure two distinct advantages; first, the binding medium between the foil and the backing or reinforcing material may be allowed to set before the disks are cut therefrom or are applied to the cork or other disk, thus securing a firm bond between the foil and its backing which it is impossible to obtain when the binding medium is applied to the foil, or the cork or other disk as the facing disk is applied thereto; second, the binding medium after it is set, will impart sufficient rigidity or crispness to the facing material to insure a clean sharp edge upon the facing disks when they are cut from a strip of the facing material.

In addition to the foregoing, I also secure the advantage that the paper or other reinforcing or backing material may have a suitable gum applied thereto prior to the feeding of the material in a machine, so that it is merely necessary to apply a damping medium to the cork or other disk to secure a firm bond between the reinforced metal foil disk and the cork or other disk. If desired the foil may be crinkled by being run between knurled rollers to produce sufficient slack therein to permit that stretch of the facing material incidental to the application of a cap to a bottle.

It is not my intention to limit the invention to the precise manner of assembling the facing material as herein described, it being apparent that the binding medium employed, as specifically referred to, is not material to the invention considered in its broader aspects.

Having described the invention, what I claim as new and desire to have protected by Letters Patent is:—

1. A facing material for cork or other disks for bottle caps consisting of metal foil provided with a reinforcement or backing of fibrous material having one surface thereof gummed and the other surface firmly bonded to said metal foil by a stratum of a binding medium.

2. A facing material for cork or other disks for bottle caps consisting of metal foil having a paper reinforcement or backing, one surface of said paper being gummed and the other surface thereof being firmly bonded to said metal foil by a stratum of a binding medium.

3. A facing material for cork or other disks for bottle caps consisting of metal foil having a paper reinforcement or backing, one surface of said paper being gummed and the other surface thereof being firmly bonded to said metal foil by a stratum of a binding medium, said paper reinforcement or backing being relatively thicker than said metal foil.

4. A facing material for cork or other disks for bottle caps consisting of metal foil provided with a reinforcement or backing of fibrous material having one surface gummed and the other surface firmly bonded to said metal foil by a stratum of a substantially non-absorbent, gas-impervious binding medium having relatively less flexibility than said metal foil or its backing.

5. A facing material for cork or other disks for bottle caps consisting of tin foil having a paper reinforcement or backing, one surface of said paper being gummed

and the other surface thereof being firmly bonded to said tin foil by a stratum of substantially non-absorbent gas impervious binding medium having relatively less flexibility than said tin foil or said paper, said paper being relatively thicker than said tin foil.

6. A facing material for cork or other disks for bottle caps consisting of metal foil provided with a reinforcement or backing of fibrous material having one surface thereof gummed and the other surface firmly bonded to said metal foil by a stratum of a binding medium, said metal foil being crinkled or indented to provide slack therein whereby said foil will be relieved from tensile strains when the bottle cap is applied to a bottle.

In witness whereof I have hereunto affixed my signature in the presence of two subscribing witnesses, this 8th day of May, 1916.

C. E. McMANUS

CUSHION MATERIAL FOR BOTTLE CLOSURES

Filed July 6, 1922

Charles E. McManus INVENTOR

BY Frank P. Wentworth

his ATTORNEY.

Patented Aug. 9, 1927. 1,638,541

UNITED STATES PATENT OFFICE.

CHARLES E. McMANUS, OF NEW YORK, N. Y.

CUSHION MATERIAL FOR BOTTLE CLOSURES.

Application filed July 6, 1922. Serial No. 573,178.

My invention relates to cushion material for bottle closures, and more particularly to material adapted to be used in lieu of the natural, or composition, cork disks now commonly used in closures of the type generally known as "Crown caps."

The main object of my invention is to provide cushion material embodying therein in a unitary structure in strip form, material having sufficient resiliency to permit the formation of a tight seal when applied under pressure to the mouth of a bottle; sufficient rigidity to permit disks to be cut therefrom and applied to the metal shell of a closure by a closure assembling machine, and a facing impermeable to gas and liquid, to be presented toward the contents of a bottle, said facing having sufficient flexibility or compressibility to yield with the cushioning portion of the material as a closure containing same is applied to a bottle in the usual manner.

The cushion material embodying my invention, preferably consists of a plurality of superimposed laminæ firmly bonded together by means of suitable binders, adhesives or glues, one outer lamina being soft vulcanized rubber or rubber substitute, and the other outer lamina being of an oil or wax fibrous material such as paper, an intermediate lamina preferably being provided for the purpose of giving additional body to the material and ensuring a better bonding of the rubber or rubber substitute lamina and the oil or wax treated lamina with relation to each other in the strip material of which they form parts.

The invention consists primarily in cushion material for bottle closures embodying therein, in a unitary structure and in strip form, a lamina of resilient material and a facing lamina permanently united thereto and consisting of a liquid and gas impervious flexible fibrous material; and in such other novel characteristics as are hereinafter set forth and described and more particularly pointed out in the claims hereto appended.

In the accompanying drawing, I have illustrated in perspective a short section of a strip of cushion material embodying my invention, broken away to disclose the different laminæ.

In the embodiment of my invention shown in the drawing, the cushion material is composed of one outer or cushion lamina *a* of soft vulcanized rubber or of a resilient rubber substitute, and the other outer lamina or facing material *b* composed of suitable fibrous material, such as paper so treated with oil or wax as to be substantially impermeable by gas and liquid such as are ordinarily present in different beverages. Said cushion lamina *a* and said facing lamina *b* are united preferably by means of an intermediate lamina *c* of fibrous material, preferably untreated paper being used, since this lamina never contacts with the contents of a bottle and a better bond may be secured when this intermediate stratum is absorptive and permeable by the binder, adhesive or glue used in uniting the cushion and facing laminæ with relation to each other through said intermediate lamina.

The cushion lamina *a* may if desired be in the form of ordinary friction rubber applied to the lamina *c*, or may be bonded thereto by means of any suitable binder, adhesive or glue, as desired.

By reason of the impregnation of the lamina *b* with oil or wax and of the necessity for securing flexibility in the binder, adhesive or glue used for uniting the lamina *b* to the intermediate lamina *c*, I preferably provide a stratum of a binder, adhesive or glue such as an asphaltum cement which has the characteristic of being moisture repellant, between the laminæ *b* and *c*, although any other flexible adhesive may be used in lieu thereof.

In the production of cushion material embodying my invention, the various laminæ are independently fed and collected, the adhesive being applied thereto during the feeding operation, said strips when collected, being forced together under pressure and preferably in an elevated temperature so as to ensure a tight continuous joint between the adjacent laminæ.

The finished strip as a whole, will possess the necessary thickness, resiliency and flexibility to permit disks cut therefrom to be used instead of cork disks in bottle closures, and possesses the further advantage that it may be used in a machine in strip form and the cushion disks cut therefrom and applied directly to the metal shell, each disk being free from surface voids of a magnitude which will not be closed as a result of the application of pressure to the closure in applying it to a bottle.

Ordinarily the thickness of the material will be approximately one-half that of the

ordinary cushion disk, it being possible with this material to cup a disk when applying it to a shell and to fold or bend the edge of the disk upon itself so as to secure an edge seal about the mouth of a bottle of greater thickness than the portion of the cushion with which the top of the mouth contacts. This thickened portion will of necessity have relatively greater resiliency than the portion with which the top of a bottle contacts, so that a tight seal may be effected at the curvature at the top of the bottle as well as at the high point of the side of the bead. Furthermore, the cushion lamina *a* when a disk is cupped and folded as described, will engage both the bead of a bottle and the material of the shell of the closure, which is a highly desirable condition in such closures.

In the production of closures embodying the cushion material of my invention, the lamina *a* will be cemented to the shell of the closure, the arrangement of this lamina, however, being such that under no circumstances can moisture or gases from the bottle penetrate through the adhesive securing the material to the shell, since the rubber or rubber substitute is immune to the action of water, and chemicals or gases ordinarily found in beverages, and furthermore when cupped will vent such matter to atmosphere if it escapes through the seal.

It is not my intention to limit the invention to the exact adhesives or glues used, since there is a wide range of selection in such materials as well as in the fibrous materials in the laminæ *b* and *c*, nor to the method of producing the material.

I have found that the lamina *b* may be made of a special well known commercial product consisting of an oil impregnated paper known in the art as insulating paper, which may be readily handled and bonded while possessing the desired non-absorptive and gas impervious properties.

Having described the invention, what I claim as new and desire to have protected by Letters Patent, is:—

1. Cushion material for bottle closures embodying therein, in a unitary structure and in strip form, a lamina of resilient material, a facing lamina consisting of liquid and gas impervious fibrous material, an intermediate lamina of fibrous material bonded to said resilient material, and a stratum of moisture resisting cement bonding said intermediate and said facing lamina.

2. Cushion material for bottle closures embodying therein, in a unitary structure and in strip form, a lamina of soft vulcanized rubber, a facing lamina consisting of liquid and gas impervious fibrous material, an intermediate lamina of fibrous material bonded to said lamina of soft vulcanized rubber, and a stratum of moisture resisting cement bonding said intermediate and said facing lamina.

3. Cushion material for bottle closures embodying therein in a unitary structure and in strip form, a lamina of resilient material, a facing lamina consisting of a liquid and gas impervious flexible fibrous material, and an intermediate lamina of absorptive, fibrous material readily permeable by a binding material, whereby the uniting of such other lamina is secured through the medium of said intermediate lamina.

4. Cushion material for bottle closures embodying therein in a unitary structure and in strip form, a lamina of soft vulcanized rubber, a facing lamina consisting of a liquid and gas impervious flexible fibrous material, and an intermediate lamina of absorptive, fibrous material readily permeable by a binding material, whereby the uniting of such other lamina is secured through the medium of said intermediate lamina.

5. Cushion material for bottle closures embodying therein in a unitary structure and in strip form, a lamina of soft vulcanized rubber, a facing lamina consisting of paper treated so as to be substantially impermeable by gases and liquids, and an intermediate lamina of non-treated paper, bonded respectively to said rubber lamina and said treated paper lamina, whereby the uniting of said other lamina is secured through the medium of said intermediate lamina.

In witness whereof I have hereunto affixed my signature, this 23rd day of June, 1922.

CHARLES E. McMANUS.

CAP INSULATOR AND MATERIAL AND PROCESS FOR MANUFACTURING THE SAME.

Application filed December 16, 1924. Serial No. 756,909.

In the marketing of preserves, mayonise, mustard, and merchandise of like charter, it is customary to use glass bottles jars equipped with metal caps, and in der that the contents of the bottle may be sulated from the metal and may be kept ee from exposure to air and dirt, it has en customary to line these metal caps ith composite discs of paper, these discs be- g varnished on the side which contacts ith the contents of the bottle so that the ntents will not soak through the paper to e metal cap where corrosion might be t up.

The present invention relates to improved sulating discs and material therefor, and to process and sub-processes whereby these roducts are produced.

Fig. 1 is a diagrammatic side elevation f apparatus employed in the first portion of h process of the present invention, and

Fig. 2 is a similar view of apparatus emloyed in the latter portion in the process f my invention.

According to the present standard prac ice the process of making cap insulators ay be described as follows:

Starting with paper three feet wide and n a 500 ft. roll, the paper is varnished on ne side by being passed over a roller which ips into a tank of varnish and thus spreads e varnish in an even layer on one side of e paper. Papers known to the trade as raft paper, express paper or rope paper, nd with a thickness of from four to six housandths of an inch before being coated re suitable for this work. The varnish ay be a pure quick drying oil varnish and ay be applied of a thickness of from one housandth to two thousandths of an inch. fter being passed over the varnishing roll e continuous sheet is suspended on a loop- and dried with heat. It requires about e half hour to dry the paper while it is oving in looped form through the drier. hen varnish is applied to one side of a per sheet in this manner it soaks through e sheet to the opposite side. Uncalendered per is ordinarily used.

After the drying above described the per is again wound up in a roll and is ready for storage, or for distribution to the consumer.

A thin varnished sheet as above described is not thick enough for successful use as a cap insulator. It must be backed up with a thicker layer of porous paper or cardboard for otherwise the insulator could not be relied on to make a tight joint between the metal cap and the glass container to which the cap is attached, usually by screw threads.

Inasmuch as the varnish has soaked through to the back surface of the paper the attachment of such a thick and porous sheet of paper or cardboard presents some difficulties. Machines have been devised for doing this work, although these machines are somewhat complex and expensive, costing in the neighborhood of $2000.00.

In such machines varnished paper in the form of a roll is unwound and passed over a roller which dips in an adhesive in a tank where it is kept hot by a gas flame. Hot gum must be used because of the presence of varnish in and on the paper sheet. Suitable gums may be made from rosin, glycerine and non-drying oils which are now available at a cost of about 18¢ per pound.

The next step in the old process consists in passing the gummed sheet through a pair of press rolls where the hot gummed side is pressed into intimate contact with a sheet of pulp board or news board unwound from a roll. This porous backing sheet may have a thickness of from twenty five thousandths to fifty thousandths of an inch. When the continuous sheet comes from rollers it is cut into rectangular panels or sheets, say three feet square. These panels are then stacked and allowed to dry for about two days. Discs cannot be punched from them immediately after they have been formed because the adhesive is still plastic enough to "gum up" any cutting dies that might be used.

After drying or aging for about two days these flat panels or sheets, according to standard practice, are placed on a wooden chopping block in a crude sort of punch press and a hollow die is moved about by hand under the platen of the press to punch

Page Tightly Bound

discs from the paper panels or sheets. These discs accumulate in the hollow punch from which they ultimately are removed and placed by hand one at a time in the caps where they are to be used, the pulp board face being placed toward the metal.

The foregoing standard practice presents the disadvantages of requiring a relatively expensive machine, a larger storage capacity at the plant, an expensive adhesive, and considerable skill and experience in the manipulation of hot gum. Even under the best of conditions, blisters will develop in the composite sheet, and finished cap insulators punched therefrom will split apart during subsequent handling and use.

All of the foregoing disadvantages of the old practice are overcome by the process hereinafter described and claimed in detail.

Referring to Fig. 1 of the drawings, the reference numeral 1 designates a roll of kraft paper, express paper or rope paper of any suitable thickness, say .004" to .006". The paper is fed over a roll 2 dipping into a tank 3 and adapted to apply a layer 4 of water soluble gum to one surface of the paper. The gum may be maintained in liquid condition by a suitable burner 5. The continuous sheet is dried in a hot box 6 and is then in condition for the application of the varnish to the opposite face. The gum or adhesive may be of the dextrine type, or may be an animal glue or may be a fish glue.

A layer of quick drying oil varnish may then be applied to the uncoated surface of the paper sheet. The paper passing from the dryer 6 may pass over suitable idler rolls 20 to reverse it and place the gummed surface uppermost. It is then passed over a roll 21 which dips into a tank 22 containing the varnish. The varnish may be maintained at any desired temperature by means of a burner 23. After a coating 24 of varnish has been applied to the paper, it may be delivered through a festooned dryer 25 looping over roller 26 arranged in the top and bottom of a dryer. The paper, coated on both surfaces, may be then wound on a roll 27. This process of varnishing the paper follows the standard practice except that the presence of the water soluble gum on the reverse side of the paper sheet prevents the varnish from soaking through it to the reversed surface.

The layer of varnish so applied can advantageously be from .001" to .002" thick.

Paper assembled in 500 ft. rolls and coated on one side with a good oil varnish and coated on the other side with a water soluble gum can be conveniently transported and is, in itself, a marketable commodity, suitable for convenient shipment to the bottle cap maker or consumer.

The varnished surface may be waxed by known processes to meet special demands of the trade, paraffin, or any good bread wrapper wax, being used for that purpose. Similarly, when a highly waterproofed cap insulator is desired, the paper may be coated with nitro cellulose and gums such as commercial dammar before the varnish is applied, and the layer of varnish can then be waxed as before.

The next step in my complete process is illustrated diagrammatically in the drawings and consists in unwinding the gummed varnish sheet from roller 8 and passing it over a roller 9, dipping in water 10. While the gummed sheet is still wet with water it is brought into contact with a sheet of pulp board or news board twenty-five to fifty thousandths of an inch thick unwound from a roll 11. The two sheets are passed between rolls 12 and 13 and thus are brought into intimate contact. The composite sheet thus formed, instead of being cut into panels and put in storage for many hours, is immediately passed to a punch press of the battery type comprising a row of plungers 14 and dies 15, whereby the desired discs can be cut simultaneously across the entire width of the composite sheet. The fact that the water soluble gum has been used as the adhesive instead of a hot rosin gum permits this prompt punching of the discs. In commercial practice, it is convenient to deliver the discs through dies 15 directly into bottle caps 16 carried on a transverse conveyor 17. Much hand operation is thus eliminated.

In the practice above described the machine is of simple and inexpensive construction, the adhesive is cheap in cost and easy to manipulate to insure a permanent close adhesion between the two sheets, and there is no need for elaborate storage space in which to age the adhering materials. But equally important, there is a prompt and orderly delivery of the finished discs, right side up in the metal caps in which they are to remain without the intervention of any substantial amount of manual handling.

I claim:

1. In a process of manufacturing cap insulators, the steps which consist in coating one side of a sheet of tough paper with a water soluble gum, then drying the gum, then varnishing the other side of said sheet and drying the varnish, subsequently wetting the gummed surface with water and bringing into contact with the wet surface a porous padding sheet, rolling said sheets together and immediately punching therefrom discs suitable for use as cap insulators, substantially as described.

2. The method which comprises coating one surface of a sheet of tough dense paper with a water soluble gum, then drying the sheet and then coating the other side of said sheet with varnish and drying and waxing

the varnish and rolling said sheet into a roll adapted for convenient storage and shipment, subsequently unrolling said gummed and varnished sheet and wetting the gummed side with water, pressing a porous paper sheet into contact with the wet gummed surface as the paper is unrolled, punching from the composite sheet so formed discs suitable for use as cap insulators and simultaneously delivering said discs directly into the caps wherein they are to be used, substantially as described.

In testimony whereof I affix my signature.

UNITED STATES PATENT OFFICE

LOUVERN G. LANGE, OF PASSAIC, NEW JERSEY

ADHESIVE BACKING

No Drawing. Application filed July 3, 1929. Serial No. 375,883.

This invention relates to adhesives and has for its object the provision of certain improvements in the method of applying and using adhesives. More particularly the invention aims to provide an improved adhesive coating for varnished or oiled papers and an improved method of applying the same.

Bottle caps, covers, container sealing devices and the like frequently are provided with a thin strip of yieldable material between the cap itself and the neck of the bottle or jar. This yieldable material frequently is in the form of a thin sheet of natural or composition cork such, for example, as the insert of cork placed within the familiar crimped-on cap of beverage bottles.

In the heretofore customary method of using bottle caps and the like it is frequently necessary or desirable to protect the cork insert from the action of the contents of the bottle or protect the contents of the bottle from the material of the cork insert. This is necessary because when composition cork is used, the binder of the fragments of cork is frequently soluble in the contents of the bottle, thus contaminating the contents of the bottle. The natural cork contains imperfections and whenever the imperfections come in contact with the edge of the neck of the bottle there is a tendency for the contents to leak and the cork insert in the bottle cap fails to seal the contents of the bottle. This makes it desirable to employ some means for protecting the surface of the cork to cover up such imperfections as may occur in the surface adjacent to the edge of the bottle neck.

The cork insert or liner may be protected by a sheet of varnished paper, the unvarnished surface of which is bonded to the cork by a material such as gutta percha. The gutta percha in sheet form may be applied to the unvarnished surface of the sheet of varnished paper and blanks may be stamped from this composite material and applied to the cork insert by hot pressing. I prefer to apply the gutta percha to the varnished paper in liquid form as hereinafter described, for in this manner it is possible to employ sufficient gutta percha to accomplish the desired result without using as much varnished paper, or as much gutta percha as is necessary when strips, or separate sheets of these materials, are combined as set forth above.

The gutta percha is customarily combined with other gums or substances in order to impart to the gutta percha other desirable properties. Balata gum and various other resins are frequently used for this purpose. Throughout this specification and the appended claim the term gutta percha is used to designate the adhesive material whether it be gutta percha alone or in combination with other substances which may slightly alter its properties.

Clean washed gutta percha may be dissolved in an appropriate volatile solvent such for example as highly refined gasoline, solvent naphtha, toluene, benzene or xylene. This solution is heated until the mass becomes thick and viscid in which state it is applied in a thin layer to the back of the varnished paper and the remaining volatile solvent permitted to evaporate.

This method of applying the gutta percha to the varnished paper permits an evenly distributed coherent layer to be applied of any appropriate thickness. The freshly dried gutta percha backing is preferably covered with talc or soapstone to overcome the tackiness of the fresh gutta percha surface.

The coating of gutta percha in solution in gasoline or other appropriate solvent is spread on the back of the treated paper or fabric in such a manner that after the solvent evaporates there is left as a backing on the treated paper a precipitated layer of gutta percha. The spreading of the solution may be so controlled that substantially any thickness of dried film may be attained. I have found it advantageous to use a finished film of substantially one thousandth (.001) of an inch in thickness with many materials, as this provides an appropriate thickness to give thorough adhesion when the paper is hot pressed on another article.

The film of gutta percha deposited from solution may be treated in any advantageous manner to eliminate the tackiness of the freshly exposed surface. I have found it advantageous to dust the surface thoroughly

with powdered talc or soapstone. The adhering layer of powdered material does not materially impair the adhesion of the gutta percha film when applied by the hot pressing method for the powdered particles are then incorporated in the body of the melted gutta percha.

The use of varnished paper provides a laminated or multi-ply fabric of great tensile strength, for the film of varnish attached to one side of the paper, the tough fibres of the paper itself and the layer of gutta percha adhering to the back of the treated paper and the other article each provides an element of added strength to the laminated or multiply assembly.

The solvent method of applying the gutta percha reduces the cost of the finished fabric not only by appreciably reducing the thickness of the gutta percha film, but also by reducing the cost by providing a more economical method of handling and preparing the materials. The gutta percha may be applied in any appropriate manner, as for example, by spreading, flooding, brushing or spraying.

I have found in the practice of the invention that the type of paper used has a great bearing on the finished material. I have found it advantageous to use a paper which has a high gloss or a polished surface. This type of paper usually has a coating of very fine material which fills in the pores of the paper itself so that the adhesive backing which is appropriately placed on the paper does not absorb nto the body of the paper as readily as when one of the softer more open grained papers is used. In other words such paper is heavily sized. Thus the adhesive backing remains for the most part on the surface of the paper and does not penetrate to any large extent into the body of the material. The adhesive backing on this type of paper is thus substantially all available to be used as an adhesive to bind the paper to any other material when it is appropriately applied by means of pressure and heat.

The composite material of the present invention is far superior to any composition, or composite material, heretofore employed as a liner or filler for bottle caps and the like. It is an established fact that even the best grades of varnished paper will absorb moisture to the extent of 12 to 13 per cent and, accordingly, the use of varnished paper in making bottle cap liners, as heretofore suggested, has been a failure. Even though the varnished paper may form an air-tight seal, yet moisture penetrates the varnished paper and attacks the underlying material, and the contents of the container is no longer effectively sealed.

The use of metal foil as a cover for cork-inserts has likewise proved to be unsatisfactory, not alone from the standpoint of the high cost of the metal foil, but also because the foil is an extremely weak material mechanically and is easily ruptured by any irregularities in the edge of the container, or by excessive pressure applied to the cap or cover enclosing the container. Attempts have been made to provide a soft cushion for the metal foil but such practice is not a satisfactory solution of the problem because of the expense of the cushion material and the fact that such precautions fail to prevent rupture of the metal foil under abnormal conditions. The foil must be very thin in order to be sufficiently flexible to conform to the configuration of the top of the container and it is impossible to make foil complying with such requirements without having the foil very weak mechanically.

The applicant has found that he can eliminate entirely the use of metal foil and at the same time provide a perfect seal for the container. In general this result is accomplished by employing a continuous film of varnish and a continuous film of gutta percha which functions as a waterproof adhesive. Paper, or the like, may have one surface provided with a continuous film of varnish and the other provided with a continuous film of gutta percha and this composite material may be bonded to an underlying layer of cork, or other resilient material. As pointed out above, the paper is preferably heavily sized to insure continuity of the films of varnish and gutta percha. The varnish film is adapted to come in contact with the contents of the container and prevent the contents from coming in contact with the gutta percha film, except in so far as moisture from within the container penetrates the varnish film and reaches the gutta percha. The moisture however cannot penetrate the gutta percha and thus it appears that a perfect seal may be formed.

The penetration and character of the finished adhesive backing is also very largely dependent upon the type of solvents which is used to dissolve the mixed gums. These solvents also have a more or less permanent effect upon the precipitated adhesive. I am not certain whether this difference is due to the fact that certain solvents are retained for a longer period by some of the gums used or whether some of the solvents promote a more thorough and complete mixture of the gums themselves. It would seem more likely that the latter is the true explanation of the difference in the adhesive backings, for it is not likely that all of the gums are equally soluble in a single solvent, but with the mixed solvents there is an intimate mixture of all the gums used. The rate of evaporation of the solvents may have something to do with the physical characteristics of the finished adhesive and by an appropriate mixture of

solvents almost any desired rate of evaporation may be obtained.

I do not wish to confine myself to any specific mixture of gums or solvents for the adhesive backing must be able to take care of a wide range of conditions. These conditions may be atmospheric or temperature conditions, thus a harder adhesive may be made to withstand summer usage or transportation conditions which may be very severe. In shipping the finished material across the United States at certain times of the year, portions of the desert districts in the West are extremely hot and this heat might cause the disintegration or sticking of a very soft or low melting point adhesive.

At certain times the adhesive backed material may be used under very cold conditions. in this case the unwinding of the rolls might cause cracking of the paper itself due to the extreme stiffness of the adhesive backing. Thus it will be seen that the adhesive backing may comprise different gums or different mixtures of gums in order to take care of extreme climatic or thermal changes.

The thickness of the adhesive coating may be varied in order to meet different conditions of use. When the material is to be applied to a very porous medium such as felt, cardboard, or even some grades of cork, it is advisable to use a thicker coating of adhesive than when the adhesive backed material is to be applied to some impervious material in the nature of metal. I have found it advantageous to use an adhesive backing of from .001 to .002 of an inch in thickness, and have found that this thickness of adhesive backing is adequate for average conditions of use although a greater thickness has at times been used in order to meet adverse conditions.

The cost of applying and using an adhesive backing of .002 of an inch in thickness or even greater thickness is less than the cost of using a thin sheet of gutta percha of the same thickness, for the waste in the adhesive backed material is substantially nil. The waste in using the thin gutta percha sheets is considerable because these sheets are delicate and are easily torn in handling, so that it is more advantageous to use a thickness of the same character with the material sprayed on or definitely attached to the paper in the manner of the present invention than it is to use the same thickness of material with sheets of gutta percha.

My improved composite material comprising paper, which has been preferably heavily sized and having a varnished surface and a surface covered with gutta percha, is especially adapted for the purpose of providing liners or inserts for bottle caps, jar covers and the like

I claim:

As a new article of manufacture, paper having a high gloss and having a coating of varnish on one surface of the paper and a coating of gutta percha on the other surface thereof.

In testimony whereof I affix my signature.

UNITED STATES PATENT OFFICE.

REINHOLD GUSTAV KOCH, OF NEW YORK, N. Y., ASSIGNOR TO SILVER CROWN DISK COMPANY, INC., A CORPORATION OF NEW YORK.

COVER FOR BOTTLE-CAP CORKS.

1,238,156. Specification of Letters Patent. Patented Aug. 28, 1917.

Application filed September 21, 1915, Serial No. 51,770. Renewed June 21, 1917. Serial No. 176,949.

To all whom it may concern:

Be it known that I, REINHOLD G. KOCH, a citizen of the United States, residing at New York, in the county of New York and State of New York, have invented certain new and useful Improvements in Covers for Bottle-Cap Corks, of which the following is a specification.

This invention relates to covers for bottle cap corks, and is intended to protect and preserve the cork disk from deterioration by exposure to the air, so that for an indefinite period of time the cork remains yielding and to a certain extent elastic. Furthermore, it is intended as an object of this invention to produce, as a new article of manufacture, a cover for bottle cap corks comprising on one surface, termed in this description the outer surface, a layer of metal foil to prevent the contact of the liquid in a bottle with the cork disk. An intermediate sheet of flexible material having a fusible coating of soft rubber on its surface next to the metal foil, and a coating or layer of gutta percha on its other or inner surface, is caused by suitable heating to adhere to the foil and to the cork disk, as more fully hereinafter set forth.

The accompanying drawings illustrate the construction and arrangement of the elements of this invention. Figure 1 represents a bottom or plan view of an ordinary bottle cap provided with a cork disk. Fig. 2 is a cross-section of a bottle cap, the cork disk of which is protected by this invention. Owing to the fact that the paper intermediate sheet, the coating of adhesive and elastic materials thereon, and the metal foil outer layer, are each relatively very thin, and cannot be adequately illustrated in a drawing such as Fig. 2 of actual size, a descriptive view, Fig. 3, is introduced to show the various elements of this invention. Fig. 3 shows a cross-section of a bottle cap, to the cork of which this invention is applied, and the scale of drawing has been considerably increased. Fig. 4 is a vertical section of the neck of a bottle, the mouth of the bottle being closed by means of a bottle cap provided with this invention, and shown in cross-section.

Throughout the drawings and description, the same letter is employed to refer to the same part.

Considering the drawings, the metal cap A is provided with the usual cork disk *a*. It is advantageous to place in the shells or metal caps A, a mixture of tartaric acid, gum arabic and rosin, which when heat is applied acts to stick the cork disk to the cap. The layer of adhesive for that purpose in Fig. 3 of the drawings is marked by the reference letter B.

As best set forth in the descriptive illustration Fig. 3, there are shown below the cork disk *a*, four layers of material. The layer C immediately next to the lower surface of the cork is gutta percha. The second layer from the cork is the intermediate sheet of tough paper. I do not limit myself to the use of any particular kind of paper, but, prefer tough paper with some absorbent and elastic quality. The reference letter D marks the intermediate paper sheet. The third sheet from the cork disk is a layer of soft vulcanized rubber E, and the surface sheet is tin foil or other metal foil F. When the four layers of material are properly arranged as described and placed in an oven and heated to a point below that of boiling water, the gutta percha and rubber soften and will adhere to and protect the cork disk. The gutta percha also adheres to and partly permeates the paper sheet. The soft vulcanized rubber also softens by the heat, adhering to the paper sheet and to the tinfoil outer surface. It will be noted that the intermediate paper sheet which forms the body layer of this invention is in itself absorbent or interstitial and more or less compressible. It will also be observed that the adhering layer of soft rubber and the fusible layer of gutta percha are insoluble in water. It has been stated that the metal foil is the outer layer, and directly covers the mouth of the bottle.

When the cork and the different layers mentioned are arranged as shown in Fig. 3, and all heated together, the top of the cork is protected by the cap, and its lower surface is fully covered and shielded from the air. The rubber layer E, protected as it is by the tinfoil, remains soft and yielding for an indefinite period of time, and when the cap provided with this invention is applied to the mouth of a bottle G, the yielding rubber layer acts to prevent the tinfoil from being torn by the usual capping pres-

sure, although the covering as well as the cork are necessarily distorted as shown in Fig. 4.

In practice it has been found that a very large proportion of the cork disks used are defective, either by reason of natural perforations or failure of the substance of the cork through age or other causes. It sometimes happens that the cork disk has a disagreeable taste or odor, which is communicated to the contents of the bottle, particularly, if the bottle has been closed by the cap for some time. By the use of this invention, the metal foil surface F is directly against the mouth of the bottle and exposed to the liquid within it. There is neither taste nor smell from the metal foil no matter how long the bottle remains capped, and, even if the cork disk is a bad one its ill effect cannot reach the interior of the bottle.

While cork is mentioned as the impervious member or layer of the composite disk for bottle caps herein specified, any selected substitute for cork may be used as the body of the disk, provided the outer layer of metal foil is adequately protected against rupture by a sufficient backing layer or layers of yielding material substantially as set forth.

Having now described this invention together with its operation and use, I claim:—

1. As a new article of manufacture, a cover for bottle cap corks, comprising an outer surface layer of metal foil, an intermediate sheet of flexible non-metallic material, a layer of elastic material arranged between the said foil and intermediate sheet and adhering to both, and a layer of gutta percha upon the exposed side of the intermediate sheet.

2. As a new article of manufacture, a disk for the interior of a bottle cap, comprising an outer layer of metal foil, an insoluble layer of soft vulcanized rubber arranged next to the metal foil and adhesively attached thereto, a body layer of flexible and compressible material arranged next to the said rubber layer, and the rubber layer being adhesively attached to the said body layer, and a layer of fusible adhesive material arranged next to the other side of the said body layer and adhesively attached thereto.

3. As a new article of manufacture, a cover for bottle cap corks, comprising an outer surface layer of metal foil, an intermediate sheet of flexible material, an adhesive coating of soft rubber connecting the said sheet and metal foil, and a fusible coating or layer of gutta percha applied to the inner side of the said sheet.

4. As a new article of manufacture, a cover for bottle cap corks, comprising an outer surface layer of metal foil, an intermediate sheet of paper, an adhesive coating of soft rubber connecting the said sheet and the metal foil, and a fusible coating or layer of gutta percha applied to the other side of the said sheet.

5. As a new article of manufacture, a disk for the interior of a bottle cap, comprising an outer layer of metal foil, an insoluble layer of soft vulcanized rubber arranged next to the metal foil and adhesively attached thereto, a body layer of absorbent and compressible material arranged next to the said rubber layer, and the said ruber layer being adhesively attached to the said body layer and partly absorbed thereby, and a layer of fusible adhesive material arranged next to the other side of the said body layer, the said fusible material being adhesively attached to the said body layer and partly absorbed thereby.

In testimony whereof I affix my signature.

REINHOLD GUSTAV KOCH.

UNITED STATES PATENT OFFICE.

FREDERICK W. FARRELL, OF BROOKFIELD, MASSACHUSETTS, ASSIGNOR TO WILLIAM MacLAURIN, OF BROOKFIELD, MASSACHUSETTS.

SEALING-STRIP.

1,358,834. Specification of Letters Patent. Patented Nov. 16, 1920.

No Drawing. Application filed December 22, 1916. Serial No. 138,471.

To all whom it may concern:

Be it known that I, FREDERICK W. FARRELL, a citizen of the United States, residing at Brookfield, in the county of Worcester and State of Massachusetts, have invented an Improvement in Sealing-Strips, of which the following is a specification.

This invention has reference to an improved sealing strip, tape, or member.

In carrying this invention into practice my attention has been directed particularly to the production of a strip, tape, stay, member having adhesive material specially adapted for the sealing of cartons, cases or containers of various kinds, but useful to secure together any two articles or parts of the same article. It being one of the objects of the invention to provide said strip, tape or member with an adhesive material which avoids the objections to the sealing tapes or members heretofore used.

It is well known that in the art of packaging articles and material by the use of cartons or containers made of fiber board or somewhat similar manufactured board it is the custom to secure the closure flaps or parts of said cartons or containers by means of strips of paper adhesively secured in place to bind or bridge edges of said flaps or parts whereby to secure said flaps or parts to one another or to some adjacent part of the carton or container. One method of securing said strips of paper or tapes has been to coat the same with glue which became hard and non-sticky or non-tacky when dry whereby the coated strips or tapes could be rolled into rolls convenient for transportation and for handling by machines in the course of their application to the cartons or containers. Usually, as a step immediately preceding the application of these strips or tapes, it has been customary to pass such strips or tapes through moistening devices to supply moisture to the glue or render the same tacky or capable of adhering to the surface to which the strip was applied.

In the course of procedure just above briefly described it has been found difficult to exactly control or determine the amount of moisture supplied to the adhesive and usually it is found that if an undue amount of moisture is supplied the surplus moisture either is distributed over the machinery, which is objectionable, or said surplus moisture unduly dissolves the glue which militates against its adhesion. It is also found that said glue is unduly expensive.

The purpose of the present invention in its more specific aspect is to provide a tape, strip, member or material having a coating of an adhesive material which can be rendered tacky without the application thereto of moisture whereby injury to the machinery is avoided and the affixing of the tape, strip, member or material to the carton or container is rendered more positive. The alternative to the use of moisture or liquid of some kind to render the adhesive of said tape, strip, etc., tacky is the use of an adhesive which, normally non-tacky, becomes tacky under a suitable increase in temperature.

The use of rubber, gutta percha, gums and other somewhat similar materials for this purpose is at present inexpedient because of their cost.

After considerable experimentation with materials of a nature to become or to remain tacky without the use of moisture I find that Trinidad asphalt is well suited for the purpose and when applied as a thin coating to a strip or sheet of paper can be utilized as an extremely strong adhesive to secure said strip or sheet of paper to another paper article particularly when the adhesion of said parts is effected under heat and pressure. I find further however that such asphalt after its application to the strip, tape or member will not harden but will remain somewhat tacky whereby the handling of said strip, tape, etc., is so difficult as to be almost impracticable and the rolling of said sealing strip, tape, etc., will not be practical because the asphaltic coating will adhere to the clean surface of said strip in the winding and prevent unwinding of the same. I am of course aware of the use of various non-adhesive coatings of loose material supplied to paper having asphaltic coatings to prevent the sticking of said coatings when wound but such loose material is not desirable and the cost of such materials is prohibitive.

In further experimentation I find it practical from all points to so load the Trinidad asphalt with an inert substance preferably of a mineral nature as to reduce the tackiness of the asphalt under ordinary temperatures so that it can be readily handled without unduly adhering to parts coming in contact therewith while under an abnormal tem-

1136

perature said asphalt will become sufficiently tacky to effect the desired adhesion and thereafter will not be affected by moisture.

I carry out my invention by subjecting the refined Trinidad asphalt to a temperature of approximately 350° F. and gradually supplying thereto dry powdered clay in proportions of about one part of clay to two parts of asphalt and thoroughly mix the same. I have however used a greater proportion of the clay or mineral than that named and have obtained good results therefrom in a mixture of six or seven parts of clay to ten parts of asphalt. The adhesive thus produced is applied as a very thin coating to a base of paper or other fabric or material and some portion of said coating may partially enter and unite with the surface structure of said base paper, fabric or material without saturating the same as the back of said base should be clean and free from adhesive. Usually said adhesive is applied to comparatively wide strips or webs of the paper, fabric or material which latter is then preferably cut into narrow strips or tapes adapted for economical and convenient use. When said adhesive coating becomes dry the strips or tapes may be wound into rolls without the layers thereof sticking together.

In some cases when a comparatively small proportion of clay is used or when the asphalt is unduly tacky I find that it is desirable to reduce the tackiness of the surface of the adhesive after its application to the paper. When this latter course is desirable or necessary I prefer to apply to the surface of the adhesive a quantity of clay or similar inert mineral matter and apply a slight friction or rubbing thereto whereby the fine particles of said clay become mechanically incorporated with or received by the asphaltic surface of the adhesive and the superficial tackiness of said surface is reduced or neutralized without materially reducing the adhesive quality of the coating when subjected to a suitable heat.

The improved sealing tapes or strips are used by placing the same with the coated surface in contact with the surface to which said strip or tape is to be affixed and applying heat and pressure to the back or uncoated surface of the strip or tape. This heat and pressure need not be applied simultaneously as the tape or strip may be subjected to heat to render the adhesive tacky or semi-fluid slightly prior to the placing of the tape or strip in position on the article to which it is to be affixed and thereafter, before the adhesive becomes set, pressure may be applied to said tape or strip to spread the adhesive and, to some extent, to force said adhesive into the surface structure of the article to which said tape or strip has been thus applied.

As the improved adhesive is not materially affected by moisture in the atmosphere its adhesive binding qualities remain practically permanent after application.

In addition to its use as a sealing tape or strip to seal or secure two adjacent flaps or parts of a carton, container or wrapper, said adhesive strips or members may be used as corner stays for boxes or other stays or reinforcing members. Said adhesive strips may be used to secure together or bridge the adjacent edges of two pieces of veneer or of any other members or articles.

It is to be understood that the inert material used to neutralize or load the asphalt should be of such extreme fineness as to its particles that said particles neither individually nor collectively will prevent any material area or quality of the asphalt from reaching the surface to which said asphalt is intended to adhere when said asphalt is subjected to a suitable temperature. I do not therefore intend to claim herein, as such inert material, the use of sand, powdered soapstone or other flaky mineral substance.

Having thus described my invention I claim as new and desire to secure by Letters Patent:

1. A sealing strip of the character described, comprising a strip of paper and a coating of asphaltum on said paper, said coating containing a sufficient proportion of pulverized mineral matter to render the asphaltum non-adhesive at normal temperatures but enabling the coating to become adhesive upon the application of heat thereto.

2. A sealing strip of the character described, comprising a strip of paper, a coating on said strip of asphaltum and pulverized mineral matter, the exposed surface of said coating having pulverized mineral matter, rubbed thereinto to render the surface of said coating non-adhesive at normal temperatures, but permitting said coating to become adhesive upon the application of heat thereto.

UNITED STATES PATENT OFFICE.

DANIEL W. JOHNSON, OF PHILADELPHIA, PENNSYLVANIA.

SEALING-DISK FOR JARS, &c.

SPECIFICATION forming part of Letters Patent No. 408,177, dated July 30, 1889.

Application filed February 16, 1889. Serial No. 300,095. (No model.)

To all whom it may concern:

Be it known that I, DANIEL W. JOHNSON, a citizen of the United States, and a resident of Philadelphia, Pennsylvania, have invented certain Improvements in Sealing-Disks for Jars, &c., of which the following is a specification.

The object of my invention is to provide a simple and effective sealing-gasket for jars, bottles, boxes, and like receptacles.

In the accompanying drawings, Figure 1 is a sectional view of the upper portion of a jar with a detached cap having my improved sealing-gasket in position therein. Fig. 2 is sectional view showing the jar sealed. Fig. 3 is a perspective view of the gasket. Figs. 4, 5, and 6 are views of other forms of gasket embodying the invention; and Fig. 7 is a sectional view showing the gasket, Fig. 5, in position on a jar. Fig. 8 is a view showing the gasket or ring on the outside of the jar-mouth.

Disks or washers for sealing-jars and other vessels having removable lids, and which are required to be air-tight, have usually been made of rubber, leather, or paper; but I have found by experiments that neither of these will keep the vessel absolutely air-tight. Of the three rubber is to be preferred; but this deteriorates and loses its elastic properties, and if used as a seal in direct contact with the articles to be preserved often taints them. Leather is also objectionable on the same account, and paper has not sufficient elasticity to make a tight joint.

I have found by experiments that by making a water-proof sealing-gasket of parchment or parchmentized fiber, or their equivalents, secured to a felted body, I am enabled to hermetically seal the vessel, while at the same time the parchment will have no deteriorating effect upon the contents of the vessel.

Referring to Fig. 3, *a* represents a disk of parchment or parchmentized fiber, which is impervious to moisture, and to which is cemented in any suitable manner a disk *b*, of any suitable felted material—such as wool, paper, &c.—providing a soft and elastic backing for the parchment. This combined felt and parchment washer is placed in the cap of a jar, as in Fig. 1, for instance, and when the cap is screwed into position, as in Fig. 2, the felt between the cap and the seat around the mouth of the vessel will be tightly compressed, making an air and water tight joint, while at the same time the contact of the contents of the vessel with the parchment will not injuriously affect said contents.

In Fig. 4 I have shown the gasket in the form of a ring, which is used in the same manner as a rubber ring, being, for instance, seated on the shoulder of a jar, as shown in Fig. 8.

Fig. 5 shows a gasket with parchment or parchment-paper disks *a a'* on both sides and felted material *b* between the two outer disks, this form of gasket being particularly available for use with a cap having an open center, as shown in Fig. 7. The disk *a'* (shown in Fig. 5) may be of plain paper—that is to say, paper not waterproofed—so that a label can be readily pasted thereon.

In Fig. 6 I have shown a disk *a*, of parchment or other water-proof material, having secured to it a ring *b*, of felt, this ring being in such position as to be compressed between the cap and the seat around the mouth of the vessel, the center portion of the disk *a*, of water-proof material, being merely for the purpose of preventing the contents of the jar from coming in contact with the lid.

It will be understood that in place of the felt, as shown, a soft yielding woven fabric may be used; but I prefer in all cases to use the felt.

I claim as my invention—

1. A sealing-gasket for jars or other vessels, having a base of water-proof material backed with and secured to a felted material, substantially as described.

2. A sealing-gasket consisting of a body of felted material having water-proof material secured to its opposite faces, substantially as described.

In testimony whereof I have signed my name to this specification in the presence of two subscribing witnesses.

DANIEL W. JOHNSON.

UNITED STATES PATENT OFFICE.

CHARLES R. KEERAN, OF BLOOMINGTON, ILLINOIS.

TOP FOR JARS.

957,664. Specification of Letters Patent. Patented May 3, 1910.

Application filed March 31, 1909. Serial No. 486,899.

To all whom it may concern:

Be it known that I, CHARLES R. KEERAN, a citizen of the United States, residing at Bloomington, in the county of McLean and State of Illinois, have invented new and useful Improvements in Tops for Jars, of which the following is a specification.

This invention relates to a seal or closures for fruit jars and other bottles, jars and similar containers.

The main object of the invention is to provide a closure of the screw cap and sealing disk type in which an improved construction of seal is employed to hermetically close the bottle or jar without undue compression of the seal.

Another object is to provide a seal which is inexpensive of construction and free from the objections incident to the use of rubber seals, and which obviates the necessity of employing enameled or porcelain-lined caps in order to prevent corrosion, thus decreasing the cost of manufacture.

Still another object is to provide a seal having improved means for maintaining a waxed disk out of contact with the cap, whereby the cap is prevented from becoming fastened to the jar by the wax and is adapted to be removed without first heating the jar to melt the wax.

In the accompanying drawing:—Figure 1 is a vertical section through the neck of a jar showing the seal in position for application. Fig. 2 is a similar view showing the neck sealed by the seal and cap. Fig. 3 is a top plan view of a portion of the cap partially broken away. Fig. 4 is a sectional view through the seal as employed in conjunction with a flanged guard ring.

Referring to the drawing, 1 designates the neck of a jar, bottle or other container having external screw threads 2, and 3 designates a metal cap having a threaded flange 4 to engage said threads 2, above its threads the flange of the cap is formed with comparatively coarse external corrugations 5, providing a milled grip for convenience in applying and removing the cap, and which corrugations also serve an additional function, as hereinafter described. The construction of seal employed allows a cap having an open center top to be employed without detriment, *i. e.*, a top having an opening 6 and consisting simply of a circular rim.

The seal employed in conjunction with the cap comprises an upper disk or liner 7 and a lower disk or liner 8. The disk 7 which forms a yielding backing for the disk 8, is formed of comparatively soft pulp board or its equivalent, while the disk 8 is composed of some soft porous material, such as blotting paper saturated with sealing wax, rubber or any of the compositions of the latter which melt at a temperature somewhat higher than normal atmospheric temperature. The disks 7 are coextensive in diameter with each other and with the internal diameter of the milled portion of the cap and external diameter of the rim edge of the neck 1. Both disks are thus adapted to fit snugly within the upper portion of the cap with the disk 7 bearing against and closing the opening 6 in the top of the cap, so that the disk 8 may rest upon the rim edge of the neck with the edges of both disks flush with the outer surface of said neck. To the under side of the disk 8 is secured a steam and water-proof disk 9 of oiled paper or any suitable material which is coextensive in diameter to the internal diameter of the neck and is adapted to fit within and bear peripherally against the same.

In use, the fruit or other substance to be preserved is poured while hot into the jar, the disks placed upon the edge of the neck as shown, the cap screwed on as far as it will go easily, and the jar allowed to stand a few minutes. The heat from the contents of the jar will soften the wax or other equivalent material saturating the disk 8, and then the cap is screwed on tightly thus embedding the rim of the neck in the waxed disk, by which a perfect hermetic seal is secured. In this operation the disk 7 will also be caused to adhere to the disk 8 by the wax, and the latter named disk will adhere so strongly to the neck that the cap may be removed and the vessel inverted and roughly handled without breaking the seal. In putting up cold goods, the waxed disk is heated in some other suitable manner prior to application and th cap screwed fully on. The disk 9 not only prevents any portion of the fused wax from entering the jar but also prevents contact of the contents

of the jar with the disk 8, and coöperates with the latter to form a more perfect seal.

It will be observed that the disks 7 and 8 completely close the joint between the neck and cap, so that no portion of the contents of the jar can come into contact with the cap. Hence, the necessity of employing an enameled or porcelain-lined cap to prevent corrosion is obviated with resulting economy. By forming the outwardly projecting corrugations on the cap the edges of the disks are allowed to lie flush with the exterior of the neck, so that they finally cover the rim edge thereof. Of course, this could be accomplished by making the cap smaller at the top and leaving off the corrugations. However, if this were done, when a wax seal is used the cap would become sealed so tightly that it would almost defy removal without heating, but even though some of the wax will stick the edges of the disks 7 and 8 to the inside points of these corrugations the portions of the wax will break loose much easier when it is desired to unscrew the cap. It will also be observed that by using a seal of the character described, the necessity of compressing the seal to an objectionable degree by a very tight screwing on of the cap as is necessary in using ordinary paper or rubber gaskets, is avoided with manifest advantages, and accordingly the cap may be made of thinner metal and with an open center, as before described, as a very strong cap is not necessary. The cost of producing the cap is therefore decreased without impairing the strength of the seal.

If desired, the annular rim or top of the cap may be depressed by inclining it slightly downward toward the opening 6, as shown in Fig. 2, thus adapting it to more effectually confine the center of the seal and sustain it against any internal pressure.

The name or trade-mark of the manufacturer or any desired printed matter may be suitably arranged on the disk 7 for display through the opening 6.

If desired, a guard ring 10 of metal or other preferred material may be provided to inclose the edges of the disks 7 and 8 said ring having an inturned flange 11 to project over upon the upper surface of the disk 7, so as to prevent contact between said disks and the cap and sticking of the disks to the cap by the sealing wax or other material. This will obviate the necessity of heating the cap to soften the wax to allow the cap to be removed and enable a cap without the corrugations to be used if so desired. Hence the cap may be easily screwed off and the seal cut away by a knife without injury or heated to soften the wax, when it may be easily removed.

Having thus fully described the invention, what I claim as new is:—

1. A closure for receptacles comprising an inner sealing disk of compressible material saturated with a sticky fusible material and adapted to rest directly upon the rim of the receptacle, an outer sealing disk backing the same, and a cap to inclose said disks and adapted to engage the receptacle.

2. A closure for receptacles comprising a sealing disk of porous compressible material saturated with a sticky fusible substance, said disk adapted to rest directly upon the rim of the receptacle, and a cap to inclose said disk and adapted for engagement with a receptacle.

3. A closure for receptacles comprising an inner sealing disk of porous compressible material saturated with a sticky fusible substance, and adapted to rest directly upon the rim of the receptacle, an outer sealing disk of compressible material backing said inner disk, and a cap inclosing said disks and adapted for engagement with a receptacle.

4. A closure for receptacles comprising an inner sealing disk of porous compressible material saturated with a sticky fusible substance and adapted to rest directly upon the rim of the receptacle, an outer sealing disk of compressible material backing said inner disk, a moisture-proof disk upon the inner face of said inner disk and of less diameter than the same, and a cap to inclose said inner and outer disks and adapted for engagement with a receptacle.

5. A closure for receptacles comprising a cap having an open center top and a threaded flange, the wall of the top being inclined inwardly and downwardly, an inner disk of porous compressible material saturated with a sticky fusible material and adapted to fit within the cap and rest directly upon the rim of the receptacle, and an outer disk of compressible material adapted to fit within the cap and to bear against said inclined wall.

6. A bottle seal comprising a cap having a flange threaded at its lower portion and provided above the threads with annular corrugations, an outer sealing disk formed of soft compressible material having its peripheral edge contacting with the corrugations, and an inner sealing disk coextensive in diameter with said outer sealing disk and composed of a porous material saturated with a sticky fusible substance and adapted to rest directly upon the rim of the receptacle.

7. A bottle seal comprising a cap having a flange threaded at its lower portion and provided above the threads with annular corrugations, the top wall of the cap being formed with a central opening and being inclined inwardly and downwardly toward said opening, an outer sealing disk formed of soft compressible material having its pe-

ripheral edge contacting with the corrugations and an inner sealing disk coextensive in diameter with said outer sealing disk and composed of a porous material saturated with a sticky fusible substance and adapted to rest directly upon the rim of the receptacle.

8. A bottle seal comprising a cap having a flange threaded at its lower portion and provided above the threads with annular corrugations, an outer sealing disk formed of soft compressible material having its peripheral edge contacting with the corrugations, an inner sealing disk coextensive in diameter with said outer sealing disk and composed of a porous material saturated with a sticky fusible substance and adapted to rest directly upon the rim of the receptacle, and a waterproof disk secured to the lower face of said inner sealing disk and of less diameter than the same.

9. A bottle seal comprising a cap having a flange threaded at its lower portion and provided above the threads with annular corrugations, the top wall of the cap being formed with a central opening and being inclined inwardly and downwardly toward said opening, an outer sealing disk formed of soft compressible material having its peripheral edge contacting with the corrugations, an inner sealing disk coextensive in diameter with said outer sealing disk and composed of a porous material saturated with a sticky fusible substance and adapted to rest directly upon the rim of the receptacle, and a water-proof disk secured to the lower face of said inner sealing disk and of less diameter than the same.

10. A seal for receptacles comprising a cap containing a porous disk saturated with a fusible material and a guard between said disk and the walls of the cap.

11. A seal for receptacles comprising a cap containing a porous disk saturated with a fusible material, and a flanged guard between said disk and the walls of the cap.

12. The combination with a receptacle having external screw threads, of a cap having a flange formed at its lower portion with engaging threads and between said threads and its crown portion with outstruck corrugations, a porous disk disposed within the cap and resting directly upon the rim of the receptacle and saturated with a sticky fusible material, a second disk arranged between said porous disk and the crown of the cap, said disks having their peripheral edges terminating in line with the outer edge of the rim of the receptacle and arranged to face the corrugations of the cap, and a waterproof disk on the under side of the porous disk and disposed within the mouth of the receptacle.

In testimony whereof I affix my signature in presence of two witnesses.

TO THE COMMISSIONER OF PATENTS:

Re 19,117

Your Petitioner, ALBIN H. WARTH, a citizen of the United States, residing at Baltimore, State of Maryland, and whose post-office address is C/o Crown Cork & Seal Company, Inc., Baltimore, Maryland, prays that he may be allowed to surrender the Letters Patent No. 1,788,260 for an improvement in PROCESS OF PRODUCING CLOSURES granted to him Jan. 6, 1931, whereof CROWN CORK & SEAL COMPANY, INC., a corporation of New York, whose principal place of business is at Baltimore, Maryland, in whose behalf and with whose assent this application is made, is now the sole owner, by assignment, and that Letters Patent may be reissued to the said CROWN CORK & SEAL COMPANY, INC., for the same invention upon the annexed amended specification. With this petition is filed an abstract of title duly certified as required in such cases.

abstract of title by atty

And he hereby appoints, CUSHMAN, DARBY & CUSHMAN, a firm composed of Arlon V. Cushman, John J. Darby and William M. Cushman, of Washington, D. C., Register No. 7196, his attorneys, with full power of substitution and revocation, to prosecute this application, to make alterations and amendments therein, to receive the patent, to sign the drawings and to transact all business in the Patent Office connected therewith.

R.3

Signed at Baltimore, Maryland, this 27th day of January, 1934.

Albin H. Warth

CROWN CORK & SEAL COMPANY, INC., assignee of the entire interest in the above mentioned Letters Patent, hereby, through its duly authorized executives, assents to the accompanying application.

Frederick G. Gustafson
Vice-President

SPECIFICATION

TO ALL WHOM IT MAY CONCERN:

Be it Known, that I, ALBIN H. WARTH, a citizen of the United States, residing at Baltimore, State of Maryland, have invented new and useful improvements in PROCESS OF PRODUCING CLOSURES, of which the following is a specification:

This invention relates to a method of producing closures of the type in which a sealing disc has a metal foil facing. This type of closure is characterized by the provision, upon the interior cushion or sealing disc, of a facing or spot having a surface which protects the cushion material from the liquids and gases.

Closures of the well known crown cork type comprise a metal shell having a skirt and a resilient sealing disc usually made of cork. For some uses, the sealing discs are given a non-absorbent, gas impervious and acid resistant facing of metal foil, e. g. tin foil, or aluminum foil. Aluminum foil is characterized by the fact that it is substantially non-absorbent and gas impervious, and for this reason the same and other materials having similar characteristics are used to form facing disc or spots upon the cushion material of crown caps. Ordinarily this facing is of smaller diameter than the cork discs and such crowns are known in the trade as spot center crowns.

These spot center crowns have been produced in various ways. According to one method a slot or groove is cut in the cork disc and the spot is given an inturned rim which is inserted in the slot. This method is objectionable because of its expense and because the spots are apt to drop out. According to another method the spots are pasted to the cork discs by a casein paste or a glue. In crowns so made the spots tend to loosen as the paste or glue is attacked by the packaged liquids. Furthermore, such method involves difficulties in handling and in applying the paste or glue. According to still another method the spots are secured by an underlying tissue of gutta percha or coated paper. In crowns so made, like objections are met with. For example, one difficulty in applying discs made from separate strips, such as gas and acid resistant material and the adhesive tissue strips, has arisen from the necessity for feeding the two strips to the punching and assembly machine. There is not only difficulty in feeding the strips, but in cutting the separate tissue strip with a clean, sharp edge so as to insure the binding stratum of adhesive being coextensive in area with the disc of liquid resistant material. As will be understood, the adhesive stratum is intended to act not only as a cement, but also as a waterproof, non-absorbent, gas impervious medium for avoiding the possibility of the contents of a bottle getting between the facing disc and the material of the cap, either the metal shelf itself or a cushion disc of cork or composition cork.

Furthermore, when using superimposed strips of the facing material and of adhesive tissue, it was essential, to bond the adhesive tissue to both the material of the cushion disc in the cap and the facing material.

In preparing the rolls of facing material and adhesive tissue, the practice usually followed was to form a roll of the

tissue in strips of the desired width, and to unwind this roll and a roll of the facing material while feeding the two strips one over the other into the disc forming and assembling machine. This is a troublesome and expensive operation, because of the frequent breakage of the adhesive tissue and the necessity for using fairly heavy tissue to minimize this tendency. This is due partly to the fact that the facing material was substantially non-elastic, while the adhesive tissue possessed a certain degree of elasticity, thus introducing a factor of difficulty in securing a uniform paying of both the facing strip and the gutta percha tissue strip.

19

It is desirable, in the use of facing discs of the character above referred to, that the adhesive stratum be as thin as possible and yet be continuous throughout the entire area of the facing disc, and particularly that it be uninterrupted about the edge of this disc, since at this point the disc should be firmly bonded so as to effectively seal the joint about the edge of the facing disc. When cutting and applying the discs of material and adhesive, there is no means of ascertaining whether the desired conditions are present in the completed cap. Consequently, there is always likelihood of imperfectly faced caps being produced.

With the above conditions in mind, I have provided material, in strip form, for facing bottle caps, in which one surface of the strip is provided with a firmly adherent, continuous thin facing of adhesive, thus avoiding all necessity for assembling strips of facing material and of adhesive tissue preparatory to their use in the bottle cap facing machine, and all of the disadvantages growing out of this practice.

In the strip material of my invention, a very thin stratum of adhesive is evenly distributed upon one face of a strip of facing material. The adhesive is not only firmly bonded to this material, but has a smooth surface finish of sufficient thickness to form the desired firm bond between a disc cut from the strip

and the material of the cap to which such disc is cemented.

Furthermore, adhesive tissue must be of a thickness to have sufficient inherent strength to permit of its being stripped from a roll in a mill for working same, and to admit of its being cut to the desired width and to be handled in the winding and the disc applying machines, and during the process of its production it has more or less of a longitudinally extending grain, as distinguished from its normal granular formation.

In the application of heat, when bonding the facing material to the cap, when utilizing adhesive tissue, a tendency of the adhesive is to break up into slightly isolated, small globules, thus interrupting the continuity of the bonding stratum. Whether this is due to irregularities in the surface of the facing strip, or to a shrinkage of the adhesive tissue when fused, I have been unable to determine. In the strip of my invention, however, the adhesive is thoroughly distributed throughout one face of the facing material, and the above conditions do not develop in the subsequent handling of the strips.

It is an object of the present invention to provide a method of producing spot center crowns such that the spots are easily and economically secured to the sealing discs and such that they are firmly secured and not liable to become loosened in use.

With these general objects in view the invention consists in the method which will be first described and then more particularly pointed out in the claims.

According to the method of the present invention, the strip material having a surface which is substantially non-absorbent and gas impervious, such as metal foil, is coated with a substance that is devoid of tackiness when dry and has adhesive qualities when soft. In carrying out the method according to what is con-

sidered the best practice the adhesive substance is such that it can be applied cold, i. e. at room temperatures, and is waterproof or insoluble in cold water. While various materials may be used I have found a suitable adhesive in a solution of damar gum and rosin in mineral spirit or turpentine, to which is added 5% or less of a vegetable oil such as soya bean or Chinawood oil. The damar gum and rosin may be in the proportion of 35% to the whole. The adhesive may have a drier of lead resinate or the like in a proportion of 2% or less. This adhesive is waterproof and is not weakened by gases or acids, such as are present in the bottle contents with which crown caps are usually employed.

While the coating may be applied to the material in various ways, it is conveniently applied in fluid form and cold to a strip of foil from which the spots are to be cut. So far as the method of producing the strip is concerned, it is such that the effective distribution of the adhesive throughout the entire area of the facing material is assured, and this condition cannot be disturbed as a result of the cutting of discs from this material when in strip form. Furthermore, the adhesive surface may be thoroughly inspected while producing the strip material, so that any imperfect product may be discarded before it reaches the disc applying machine. In this connection it is noted that the spots may be conveniently assembled by feeding a strip of material over successive crown corks and cutting out a disc which is deposited on a cork, such assembling machinery being known in the art.

14

After the coating is applied to the metal foil it is dried. While this may be effected by air drying at room temperature it is more rapidly accomplished at a temperature of about 300°F. maintained for about 30 minutes. When dried the coating is devoid of tackiness so that the metal foil may be handled without difficulty or trouble. This is particularly advantageous when the metal foil is to be fed in strips because the application of

the adhesive is carried out independently of the assembling steps. Moreover, the coating gives the thin metal foil more or less body which facilitates feeding and cutting. Since the adhesive is applied directly to the surface of the facing or spot material and firmly bonded thereto, there is no likelihood of difficulties arising as a result of separation of the adhesives from the facing strip during the spot forming operation, either as a result of poor adherence or from suction or otherwise, such as frequently occurs when using superimposed strips of facing material and of adhesive tissue. Moreover, in handling this material the adhesive stratum is incapable of stretch or distortion relative to the spot strip as frequently occurs in the handling of separate strips of adhesive tissue and facing material where any stretch or distortion of the adhesive stratum results in a defective cap and when the stretch is extreme, tearing of the adhesive tissue makes necessary the stoppage of the cap machine until the strip can be repaired.

After the coating is dry, the metal foil spots are assembled, coated side down, with the sealing discs. In case the metal foil is fed in a strip, spots may be cut out and deposited on the sealing disc, as above set forth.

At the time of assembly the coating material is softened to render it adhesive and the assembled unit is subjected to pressure. In carrying out the invention according to what is now considered the best practice the coating will be softened by heat after the crown is assembled. In cutting discs from this improved laminated strip having an adhesive stratum bonded thereto, there is no tendency toward mutilation of the adhesive layer by reason of possible drag of the cutting dies, and each disc, as delivered from the die to within a cap, will present a continuous uninterrupted adhesive surface upon the disc so as to insure, by the subsequent application of heat and pressure, a bond between the disc and the cap cushion layer coextensive in

area with the disc.

This possibility of securing a clean cut by the dies for forming the discs, both as to the non-absorptive and gas impervious, and as to the adhesive stratum, insures an effective bond entirely about the edge of the spot or disc, thereby presenting a continuous barrier of non-absorptive and gas impervious material at the space between the disc and the cap which will effectively prevent the seepage of gas or fluid in a bottle between the disc and the portion of the cap to which it is applied.

Although the adhesive facing is sufficiently thick to provide an adhesive stratum or layer, it is sufficiently thin to avoid any tendency toward the expression during the application of pressure of any of the adhesive from between the facing material and the portion of the cap to which it is applied. This may be accomplished in any suitable manner, as by a heated plunger or a plunger and heated table. The heat softens the coating and renders it adhesive and the pressure serves to unite the metal foil spot to the cork.

Referring to the accompanying drawings, there is shown suitable mechanism for coating the strip and for cutting discs therefrom and adhesively uniting the disc to caps at the time of the assembly of the discs with the caps. In the drawings,

Figure 1 is a diagrammatical view showing the coating of the strip.

Figure 2 is a longitudinal sectional view of a fragment of the strip.

Figure 3 is a side elevational view partly in section showing one step in the assembly operation.

Figure 4 is a view similar to Figure 3 showing the spot as it is cut and adhesively united to the cap at the time of assembly.

Figure 5 is an interior face view of the completed cap, and

Figure 6 is a cross sectional view of the cap shown in Figure 5.

The strip of facing material should have the characteristic of aluminum foil. That is to say, it should present one surface which is non-absorbent and gas impervious. This strip may be fed from a reel 10 to a reel 11, suitably separated so that the adhesive coating may be applied and hardened between the time any portion of the strip leaves the reel 10 and is wound upon the reel 11. For the purpose of applying the adhesive, the same may be maintained in a trough 12, positioned beneath an adhesive applying roll 13, between which and a roll 14, the strip passes, so that as the rolls are rotated the adhesive is applied to the undersurface thereof. As will be understood, the adhesive hardens between the time it is applied and the winding of the laminated strip upon the reel 11.

The completed spot material or liner is illustrated in Figure 2, and comprises the layer 15 of non-absorbent and gas impervious material, such as aluminum foil having on one surface the coating 16 of adhesive, which is preferably of the character hereinbefore described. This adhesive is waterproof or liquid resistant, and will be normally hard, i. e. non-tacky, at room temperature so that the material may be conveniently handled in strip form, but quickly softens under the application of heat, becoming tacky, so that upon the application of pressure, the laminated disc will be adhesively retained in the cap. The preferred method of applying the material to the cap is to utilize, at the time of assembly, both heat and pressure to unite the spot to the cork or cushion material insert or facing of the cap.

In Figures 3 and 4, there is shown a suitable mechanism for applying the disc and adhesively uniting it to the cork insert at the time the strip is punched from the disc and assembled with the cap.

The cap 17 is of the conventional crown type having an interior facing 18 of cushion material, such as composition cork retained in the cap as by an adhesive layer 17'; the cushion disc and adhesive may be applied to the cap in any suitable manner, for example, as described in the patent to Marsa, No. 1,603,786, granted Oct. 19, 1926. The caps, with the cushion discs inserted therein, may be positioned beneath the cutting dies 19, 20, by means of a traveling bed 21 having suitable sockets for receiving the cap so as to position the same accurately beneath the cutting dies. The strip material for forming the spot is fed beneath the die 20 with the adhesive coating 16 facing the cap, and when the die descends it will cut from the strip, which is fed by any suitable means (not shown), a spot or facing 22 of the character illustrated in Figures 5 and 6. The spot or disc is preferably of smaller diameter than the cap facing so as to form a substantially centrally disposed spot which leaves around its edge an exposed portion of the cushion material adapted to engage the edge of a bottle neck, the spot being of sufficient size to close the bottle mouth and prevent contact of the contents with the cushion material.

As will be observed (Figures 3 and 4) as the punch 20 descends, it cuts from the strip a spot of the size shown in Figure 5, and continued downward movement presses this disc upon the cushion layer 18.

The punch 20 may be maintained at an elevated temperature, as by means of a burner 23, and the temperature should be sufficient to fuse or soften the adhesive coating and make it tacky so that, at the time the disc is assembled with the cap, the heat and pressure will cause the disc to be adhesively united to the surface of the cushion material with sufficient permanency to insure that the position will be retained and avoid likelihood of displacement of the disc thereafter.

The assembled unit is then permitted to cool and the cooling may advantageously be coupled with pressure, for example, by a plunger. Cooling may be effected in any suitable manner, being carried out to the congealing point of the coating material.

The resulting crown has a firmly secured metal foil spot which is not liable to become loose in use owing to the fact that the adhesive substance is not soluble in liquids more commonly sealed by crown corks. Moreover, when the metal foil is assembled with the sealing disc it is already prepared for being stuck in place, the sticking being accomplished by the simple application of heat and pressure. The coating operation is a simple one and the coated metal foil is easily handled because the dry coating is not tacky.

A cap made in accordance with this method possesses the advantage of a substantially uniform and complete distribution of the adhesive layer throughout each spot or facing disc. The method has the advantage of eliminating the labor of associating a separate adhesive strip and a strip of facing material, and the further advantage of enabling higher speeds to be maintained in the facing spot applying machine. The elimination of the danger of breakage of a separate adhesive tissue strip avoids the frequent stoppage of the machine, which was unavoidable due to the handling of the somewhat fragile and elastic adhesive tissue.

What is claimed is:

1. The improved method of manufacturing caps of the type having an interior disc of cushion material provided on its exposed face with a center spot, which comprises providing spot material in strip form having one surface formed of an exposed continuous coating of water resistant adhesive which is normally hard at room temperature but becomes tacky upon the application of heat and having another surface to be exposed to the contents of a capped container, cutting from said strip a facing spot having one surface completely coated with said adhesive with a cap disposed beneath the portion of the strip from which the spot is cut, whereby the cutting operation positions the spot upon the cushion material with the coating between the spot and the cushion material, and upon assembly applying simultaneously to the spot pressure and sufficient heat to render the adhesive tacky, thereby causing the spot to adhere to the cushion material, and thereafter permitting the adhesive to cool and harden.

2. The improved method of manufacturing caps of the type having an interior disc of cushion material provided on its exposed face with a center spot, which comprises providing metal foil spot material in strip form having one surface formed of an exposed continuous coating of water resistant adhesive which is normally hard at room temperature but becomes tacky upon the application of heat and having another surface to be exposed to the contents of a capped container, cutting from said metal foil strip a facing spot having one surface completely coated with said adhesive with a cap disposed beneath the portion of the strip from which the spot is cut, whereby the cutting operation positions the spot upon the cushion material with the coating between the spot and the cushion material, and upon assembly applying simultaneously to the spot pressure and sufficient heat to render the adhesive tacky, thereby causing the spot to adhere to the cushion material, and thereafter permitting the adhesive to cool and harden.

3. The improved method of manufacturing caps of the type having an interior disc of cushion material provided on its exposed face with a center spot, which comprises providing spot material in strip form having one surface formed of an exposed continuous coating of water resistant adhesive which is normally hard at room temperature but becomes tacky upon the application of heat and having another surface to be exposed to the contents of a capped container, cutting from said strip a facing spot having one surface completely coated with said adhesive with a cap disposed beneath the portion of the strip from which the spot is cut, whereby the cutting operation positions the spot upon the cushion material with the coating between the spot and the cushion material, and upon assembly applying simultaneously to the spot pressure and sufficient heat to render the adhesive tacky, thereby causing the spot to adhere to the cushion material and thereafter permitting the adhesive to cool and harden while subjecting the assembled unit to pressure.

1158

4. The improved method of manufacturing caps of the type having an interior disc of cushion material provided on its exposed face with a center spot, which comprises providing metal foil spot material in strip form having one surface formed or an exposed continuous coating of water resistant adhesive which is normally hard at room temperature but becomes tacky upon the application of heat and having another surface to be exposed to the contents of a capped container, cutting from said metal foil strip a facing spot having one surface completely coated with said adhesive with a cap disposed beneath the portion of the strip from which the spot is cut, whereby the cutting operation positions the spot upon the cushion material with the coating between the spot and the cushion material, and upon assembly applying simultaneously to the spot pressure and sufficient heat to render the adhesive tacky, thereby causing the spot to adhere to the cushion material, and thereafter permitting the adhesive to cool and harden while subjecting the assembled unit to pressure.

Sig

In testimony whereof, I have hereunto set my hand this [illegible] day of [illegible] 1934.

OATH

CITY OF BALTIMORE)
STATE OF MARYLAND) ss.

ALBIN H. WARTH, the above named Petitioner, being duly sworn, deposes and says that he does verily believe himself to be the original, first, and sole inventor of the improvement set forth and claimed in the foregoing specification and for which improvement he solicits a patent; that deponent does not know and does not believe that said improvement was ever before known or used; that deponent is a citizen of the United States of America, and resides at Baltimore, State of Maryland; that deponent verily believes that the Letters Patent referred to in the foregoing petition and specification and herewith surrendered are inoperative, for the reasons that the specification thereof is defective and insufficient, and that such defect and insufficiency consists in the typographical error in the specification that the coating is dried at a temperature of about 300°F. for thirty minutes instead of three minutes, and particularly in the failure to submit claims which include or recite that step in the method which involves the application of pressure, for example, by a plunger, while the thermo-plastic adhesive uniting the center spot to the cork disc is permitted to cool; and deponent further says that the errors which render such patent so inoperative arose from inadvertence, accident or mistake, and without any fradulent or deceptive intention on the part of deponent; that the following is a true specification of the errors which it is claimed constitut such inadvertence, accident or mistake relied upon:

As indicated by the record of the patent, applicant was the first to invent a process including the steps set forth in the two claims appearing in the original patent. The original application was prosecuted by applicant's attorneys with full recognition of this fact. Moreover, one step in applicant's method as disclosed in his specification is that the cooling of the assembled unit "may advantageously be coupled with pressure, for example, by a plunger. Cooling may be effected in any suit-

able manner, being carried out to the congealing point of the coating or adhesive material" on the strip from which the center spot is punched. Since the issuance of the patent, however, and only very recently, it has come to applicant's attention that the claims allowed do not recite, in addition to the steps therein set forth, the step of applying pressure to the assembled unit while the coating or adhesive material is congealing. There was no intention either on the part of applicant or his attorneys to omit claims to this step of the method and, as a matter of fact, applicant has always been under the impression that the patent, as granted, included claims covering this step in the method. More particularly, the defect in the specification resides in the failure to set forth the invention somewhat more fully than the present claims by the presentation of claims such as the following:

> 3. The improved method of manufacturing caps of the type having an interior disc of cushion material provided on its exposed face with a center spot, which comprises providing spot material in strip form having one surface formed of an exposed continuous coating of water resistant adhesive which is normally hard at room temperature but becomes tacky upon the application of heat and having another surface to be exposed to the contents of a capped container, cutting from said strip a facing spot having one surface completely coated with said adhesive with a cap disposed beneath the portion of the strip from which the spot is cut, whereby the cutting operation positions the spot upon the cushion material with the coating between the spot and the cushion material, and upon assembly applying simultaneously to the spot pressure and sufficient heat to render the adhesive tacky, thereby causing the spot to adhere to the cushion material, and thereafter permitting the adhesive to cool and harden while subjecting the assembled unit to pressure.
>
> 4. The improved method of manufacturing caps of the type having an interior disc of cushion material provided on its exposed face with a center spot, which comprises providing metal foil spot material in strip form having one surface formed of an exposed continuous coating of water resistant adhesive which is normally hard at room temperature but becomes tacky upon the application of heat and having another surface to be exposed to the contents of a capped container, cutting from said metal foil strip a facing spot having one surface completely coated with said

OCC/22

adhesive with a cap disposed beneath the portion of the strip from which the spot is cut, whereby the cutting operation positions the spot upon the cushion material with the coating between the spot and the cushion material, and upon assembly applying simultaneously to the spot pressure and sufficient heat to render the adhesive tacky, thereby causing the spot to adhere to the cushion material, and thereafter permitting the adhesive to cool and harden while subjecting the assembled unit to pressure.

That such errors so particularly specified arose as follows: Applicant explained to his original attorneys the complete method as set forth in the original application filed January 7, 1927, as Serial No. 159,743, and the said specification was prepared on the basis of information applicant conveyed to said attorneys. Upon the issuance of the patent on January 6, 1931, applicant reviewed the specification and claims and, being unfamiliar with the interpretation of claims, assumed from the fact that the specification referred to the application of pressure, and from the further fact that the claims allowed referred to the cooling and hardening of the adhesive, that this pressure step of the method was covered. Applicant is not skilled in patent procedure or the interpretation of claims and until recently informed by his attorneys that claims specifically defining the application of pressure would be allowable, in addition to the claims of the patent, and are in fact required in order to cover this additional step, did not consider that there was any defect or insufficient in the patent. When it did come to applicant's attention that the step of applying pressure during the cooling operation should be expressly recited in the claims, he immediately caused his present attorneys to present this application for reissue.

UNITED STATES PATENT OFFICE

ALBIN H. WARTH, OF BALTIMORE, MARYLAND, ASSIGNOR, BY MESNE ASSIGNMENTS, TO CROWN CORK & SEAL COMPANY, INC., OF NEW YORK, N. Y., A CORPORATION OF NEW YORK

PROCESS OF PRODUCING CLOSURES

REISSUED

Application filed January 7, 1927. Serial No. 159,743.

This invention relates to a method of producing closures of the type in which a sealing disk has a metal foil facing. This type of closure is characterized by the provision, upon the interior cushion or sealing disc, of a facing or spot having a surface which protects the cushion material from the liquids and gases.

Closures of the well known crown cork type comprise a metal shell having a skirt and a resilient sealing disk usually made of cork. For some uses, the sealing disks are given a non-absorbent, gas impervious and acid resistant facing of metal foil, e. g. tin foil, or aluminum foil. Aluminum foil is characterized by the fact that it is substantially non-absorbent and gas impervious, and for this reason the same and other materials having similar characteristics are used to form facing disc or spots upon the cushion material of crown caps. Ordinarily this facing is of smaller diameter than the cork disks and such crowns are known in the trade as spot center crowns.

These spot center crowns have been produced in various ways. According to one method a slot or groove is cut in the cork disk and the spot is given an inturned rim which is inserted in the slot. This method is objectionable because of its expense and because the spots are apt to drop out. According to another method the spots are pasted to the cork disks by a casein paste or a glue. In crowns so made the spots tend to loosen as the paste or glue is attacked by the packaged liquids. Furthermore, such method involves difficulties in handling and in applying the paste or glue. According to still another method the spots are secured by an underlying tissue of gutta percha or coated paper. In crowns so made, like objections are met with. For example, one difficulty in applying discs made from separate strips, such as gas and acid resistant material and the adhesive tissue strips, has arisen from the necessity for feeding the two strips to the punching and assembly machine. There is not only difficulty in feeding the strips, but in cutting the separate tissue strip with a clean, sharp edge so as to insure the binding stratum of adhesive being coextensive in area with the disc of liquid resistant material. As will be understood, the adhesive stratum is intended to act not only as a cement, but also as a waterproof, non-absorbent, gas impervious medium for avoiding the possibility of the contents of a bottle getting between the facing disc and the material of the cap, either the metal shelf itself or a cushion disc of cork or composition cork.

Furthermore, when using superimposed strips of the facing material and of adhesive tissue, it was essential, to bond the adhesive tissue to both the material of the cushion disc in the cap and the facing material.

In preparing the rolls of facing material and adhesive tissue, the practice usually followed was to form a roll of the tissue in strips of the desired width, and to unwind this roll and a roll of the facing material while feeding the two strips one over the other into the disc forming and assembling machine. This is a troublesome and expensive operation, because of the frequent breakage of the adhesive tissue and the necessity for using fairly heavy tissue to minimize this tendency. This is due partly to the fact that the facing material was substantially non-elastic, while the adhesive tissue possessed a certain degree of elasticity, thus introducing a factor of difficulty in securing a uniform paying of both the facing strip and the gutta percha tissue strip.

It is desirable, in the use of facing disks of the character above referred to, that the adhesive stratum be as thin as possible, and yet be continuous throughout the entire area of the facing disk, and particularly that it be uninterrupted about the edge of this disk, since at this point the disk should be firmly bonded so as to effectively seal the joint about the edge of the facing disk. When cutting and applying the disks of material and adhesive, there is no means of ascertaining whether the desired conditions are present in the completed cap. Consequently, there is always likelihood of imperfectly faced caps being produced.

With the above conditions in mind, I have provided material, in strip form, for facing

bottle caps, in which one surface of the strip is provided with a firmly adherent, continuous thin facing of adhesive, thus avoiding all necessity for assembling strips of facing material and of adhesive tissue preparatory to their use in the bottle cap facing machine, and all of the disadvantages growing out of this practice.

In the strip material of my invention, a very thin stratum of adhesive is evenly distributed upon one face of a strip of facing material. The adhesive is not only firmly bonded to this material, but has a smooth surface finish of sufficient thickness to form the desired firm bond between a disk cut from the strip and the material of the cap to which such disk is cemented.

Furthermore, adhesive tissue must be of a thickness to have sufficient inherent strength to permit of its being stripped from a roll in a mill for working same, and to admit of its being cut to the desired width and to be handled in the winding and the disk applying machines, and during the process of its production it has more or less of a longitudinally extending grain, as distinguished from its normal granular formation.

In the application of heat, when bonding the facing material to the cap, when utilizing adhesive tissue, a tendency of the adhesive is to break up into slightly isolated, small globules, thus interrupting the continuity of the bonding stratum. Whether this is due to irregularities in the surface of the facing strip, or to a shrinkage of the adhesive tissue when fused, I have been unable to determine. In the strip of my invention, however, the adhesive is thoroughly distributed throughout one face of the facing material, and the above conditions do not develop in the subsequent handling of the strips.

It is an object of the present invention to provide a method of producing spot center crowns such that the spots are easily and economically secured to the sealing disks and such that they are firmly secured and not liable to become loosened in use.

With these general objects in view the invention consists in the method which will be first described and then more particularly pointed out in the claims.

According to the method of the present invention, the strip material having a surface which is substantially non-absorbent and gas impervious, such as metal foil, is coated with a substance that is devoid of tackiness when dry and has adhesive qualities when soft. In carrying out the method according to what is considered the best practice the adhesive substance is such that it can be applied cold, i. e. at room temperatures, and is waterproof or insoluble in cold water. While various materials may be used I have found a suitable adhesive in a solution of damar gum and rosin in mineral spirit or turpentine, to which is added 5% or less of a vegetable oil such as soya bean or China-wood oil. The damar gum and rosin may be in the proportion of 35% to the whole. The adhesive may have a drier of lead resinate or the like in a proportion of 2% or less. This adhesive is waterproof and is not weakened by gases or acids, such as are present in the bottle contents with which crown caps are usually employed.

While the coating may be applied to the material in various ways, it is conveniently applied in fluid form and cold to a strip of foil from which the spots are to be cut. So far as the method of producing the strip is concerned, it is such that the effective distribution of the adhesive throughout the entire area of the facing material is assured, and this condition cannot be disturbed as a result of the cutting of discs from this material when in strip form. Furthermore, the adhesive surface may be thoroughly inspected while producing the strip material, so that any imperfect product may be discarded before it reaches the disc applying machine. In this connection it is noted that the spots may be conveniently assembled by feeding a strip of material over successive crown corks and cutting out a disk which is deposited on a cork, such assembling machinery being known in the art.

After the coating is applied to the metal foil it is dried. While this may be effected by air drying at room temperature it is more rapidly accomplished at a temperature of about 300° F. maintained for about 30 minutes. When dried the coating is devoid of tackiness so that the metal foil may be handled without difficulty or trouble. This is particularly advantageous when the metal foil is to be fed in strips because the application of the adhesive is carried out independently of the assembling steps. Moreover, the coating gives the thin metal foil more or less body which facilitates feeding and cutting. Since the adhesive is applied directly to the surface of the facing or spot material and firmly bonded thereto, there is no likelihood of difficulties arising as a result of separation of the adhesive from the facing strip during the spot forming operation, either as a result of poor adherence or from suction or otherwise, such as frequently occurs when using superimposed strips of facing material and of adhesive tissue. Moreover, in handling this material the adhesive stratum is incapable of stretch or distortion relative to the spot strip as frequently occurs in the handling of separate strips of adhesive tissue and facing material where any stretch or distortion of the adhesive stratum results in a defective cap and when the stretch is extreme, tearing of the adhesive tissue makes necessary the stoppage of the cap machine until the strip can be repaired.

After the coating is dry, the metal foil spots

are assembled, coated side down, with the sealing disks. In case the metal foil is fed in a strip, spots may be cut out and deposited on the sealing disk, as above set forth.

At the time of assembly the coating material is softened to render it adhesive and the assembled unit is subjected to pressure. In carrying out the invention according to what is now considered the best practice the coating will be softened by heat after the crown is assembled. In cutting discs from this improved laminated strip having an adhesive stratum bonded thereto, there is no tendency toward mutilation of the adhesive layer by reason of possible drag of the cutting dies, and each disc, as delivered from the die to within a cap, will present a continuous uninterrupted adhesive surface upon the disc so as to insure, by the subsequent application of heat and pressure, a bond between the disc and the cap cushion layer coextensive in area with the disc.

This possibility of securing a clean cut by the dies for forming the discs, both as to the non-absorptive and gas impervious, and as to the adhesive stratum, insures an effective bond entirely about the edge of the spot or disc, thereby presenting a continuous barrier of non-absorptive and gas impervious material at the space between the disc and the cap which will effectively prevent the seepage of gas or fluid in a bottle between the disc and the portion of the cap to which it is applied.

Although the adhesive facing is sufficiently thick to provide an adhesive stratum or layer, it is sufficiently thin to avoid any tendency toward the expression during the application of pressure of any of the adhesive from between the facing material and the portion of the cap to which it is applied. This may be accomplished in any suitable manner, as by a heated plunger or a plunger and heated table. The heat softens the coating and renders it adhesive and the pressure serves to unite the metal foil spot to the cork.

Referring to the accompanying drawings, there is shown suitable mechanism for coating the strip and for cutting discs therefrom and adhesively uniting the disc to caps at the time of the assembly of the discs with the caps. In the drawings,

Figure 1 is a diagrammatical view showing the coating of the strip.

Figure 2 is a longitudinal sectional view of a fragment of the strip.

Figure 3 is a side elevational view partly in section showing one step in the assembly operation.

Figure 4 is a view similar to Figure 3 showing the spot as it is cut and adhesively united to the cap at the time of assembly.

Figure 5 is an interior face view of the completed cap, and

Figure 6 is a cross sectional view of the cap shown in Figure 5.

The strip of facing material should have the characteristic of aluminum foil. That is to say, it should present one surface which is non-absorbent and gas impervious. This strip may be fed from a reel 10 to a reel 11, suitably separated so that the adhesive coating may be applied and hardened between the time any portion of the strip leaves the reel 10 and is wound upon the reel 11. For the purpose of applying the adhesive, the same may be maintained in a trough 12, positioned beneath an adhesive applying roll 13, between which and a roll 14, the strip passes, so that as the rolls are rotated the adhesive is applied to the undersurface thereof. As will be understood, the adhesive hardens between the time it is applied and the winding of the laminated strip upon the reel 11.

The completed spot material or liner is illustrated in Figure 2, and comprises the layer 15 of non-absorbent and gas impervious material, such as aluminum foil having on one surface the coating 16 of adhesive, which is preferably of the character hereinbefore described. This adhesive is waterproof or liquid resistant, and will be normally hard, i. e. non-tacky, at room temperature so that the material may be conveniently handled in strip form, but quickly softens under the application of heat, becoming tacky, so that upon the application of pressure, the laminated disc will be adhesively retained in the cap. The preferred method of applying the material to the cap is to utilize, at the time of assembly, both heat and pressure to unite the spot to the cork or cushion material insert or facing of the cap.

In Figures 3 and 4, there is shown a suitable mechanism for applying the disc and adhesively uniting it to the cork insert at the time the strip is punched from the disc and assembled with the cap.

The cap 17 is of the conventional crown type having an interior facing 18 of cushion material, such as composition cork retained in the cap as by an adhesive layer 17′; the cushion disc and adhesive may be applied to the cap in any suitable manner, for example as described in the patent to Marsa, No. 1,603,786, granted Oct. 19, 1926. The caps, with the cushion discs inserted therein, may be positioned beneath the cutting dies 19, 20, by means of a traveling bed 21 having suitable sockets for receiving the cap so as to position the same accurately beneath the cutting dies. The strip material for forming the spot is fed beneath the die 20 with the adhesive coating 16 facing the cap, and when the die descends it will cut from the strip, which is fed by any suitable means (not shown), a spot or facing 22 of the character illustrated in Figures 5 and 6. The spot or disc is preferably of smaller diameter than the cap facing so as to form a substantially centrally

disposed spot which leaves around its edge an exposed portion of the cushion material adapted to engage the edge of a bottle neck, the spot being of sufficient size to close the bottle mouth and prevent contact of the contents with the cushion material.

As will be observed (Figures 3 and 4) as the punch 20 descends, it cuts from the strip a spot of the size shown in Figure 5, and continued downward movement presses this disc upon the cushion layer 18.

The punch 20 may be maintained at an elevated temperature, as by means of a burner 23, and the temperature should be sufficient to fuse or soften the adhesive coating and make it tacky so that, at the time the disc is assembled with the cap, the heat and pressure will cause the disc to be adhesively united to the surface of the cushion material with sufficient permanency to insure that the position will be retained and avoid likelihood of displacement of the disc thereafter.

The assembled unit is then permitted to cool and the cooling may advantageously be coupled with pressure, for example, by a plunger. Cooling may be effected in any suitable manner, being carried out to the congealing point of the coating material.

The resulting crown has a firmly secured metal foil spot which is not liable to become loose in use owing to the fact that the adhesive substance is not soluble in liquids more commonly sealed by crown corks. Moreover, when the metal foil is assembled with the sealing disk it is already prepared for being stuck in place, the sticking being accomplished by the simple application of heat and pressure. The coating operation is a simple one and the coated metal foil is easily handled because the dry coating is not tacky.

A cap made in accordance with this method possesses the advantage of a substantially uniform and complete distribution of the adhesive layer throughout each spot or facing disc. The method has the advantage of eliminating the labor of associating a separate adhesive strip and a strip of facing material, and the further advantage of enabling higher speeds to be maintained in the facing spot applying machine. The elimination of the danger of breakage of a separate adhesive tissue strip avoids the frequent stoppage of the machine, which was unavoidable due to the handling of the somewhat fragile and elastic adhesive tissue.

What is claimed is:

1. The improved method of manufacturing caps of the type having an interior disc of cushion material provided on its exposed face with a center spot, which comprises providing spot material in strip form having one surface formed of an exposed continuous coating of water resistant adhesive which is normally hard at room temperature but becomes tacky upon the application of heat and having another surface to be exposed to the contents of a capped container, cutting from said strip a facing spot having one surface completely coated with said adhesive with a cap disposed beneath the portion of the strip from which the spot is cut, whereby the cutting operation positions the spot upon the cushion material with the coating between the spot and the cushion material, and upon assembly applying simultaneously to the spot pressure and sufficient heat to render the adhesive tacky, thereby causing the spot to adhere to the cushion material, and thereafter permitting the adhesive to cool and harden.

2. The improved method of manufacturing caps of the type having an interior disc of cushion material provided on its exposed face with a center spot, which comprises providing metal foil spot material in strip form having one surface formed of an exposed continuous coating of water resistant adhesive which is normally hard at room temperature but becomes tacky upon the application of heat and having another surface to be exposed to the contents of a capped container, cutting from said metal foil strip a facing spot having one surface completely coated with said adhesive with a cap disposed beneath the portion of the strip from which the spot is cut, whereby the cutting operation positions the spot upon the cushion material with the coating between the spot and the cushion material, and upon assembly applying simultaneously to the spot pressure and sufficient heat to render the adhesive tacky, thereby causing the spot to adhere to the cushion material, and thereafter permitting the adhesive to cool and harden.

In testimony whereof, I have hereunto set my hand.

Original No. 1,788,266, dated January 6, 1931, Serial No. 159,743, January 7, 1927. Application for reissue January 23, 1934. Serial No. 707,995

4 Claims. (Cl. 113—80)

This invention relates to a method of producing closures of the type in which a sealing disc has a metal foil facing. This type of closure is characterized by the provision, upon the interior cushion or sealing disc, of a facing or spot having a surface which protects the cushion material from the liquids and gases.

Closures of the well known crown cork type comprise a metal shell having a skirt and a resilient sealing disc usually made of cork. For some uses, the sealing discs are given a non-absorbent, gas impervious and acid resistant facing of metal foil, e. g. tin foil, or aluminum foil. Aluminum foil is characterized by the fact that it is substantially non-absorbent and gas impervious, and for this reason the same and other materials having similar characteristics are used to form facing disc or spots upon the cushion material of crown caps. Ordinarily this facing is of smaller diameter than the cork discs and such crowns are known in the trade as spot center crowns.

These spot center crowns have been produced in various ways. According to one method a slot or groove is cut in the cork disc and the spot is given an inturned rim which is inserted in the slot. This method is objectionable because of its expense and because the spots are apt to drop out. According to another method the spots are pasted to the cork discs by a casein paste or a glue. In crowns so made the spots tend to loosen as the paste or glue is attacked by the packaged liquids. Furthermore, such method involves difficulties in handling and in applying the paste or glue. According to still another method the spots are secured by an underlying tissue of gutta percha or coated paper. In crowns so made, like objections are met with. For example, one difficulty in applying discs made from separate strips, such as gas and acid resistant material and the adhesive tissue strips, has arisen from the necessity for feeding the two strips to the punching and assembly machine. There is not only difficulty in feeding the strips, but in cutting the separate tissue strip with a clean, sharp edge so as to insure the binding stratum of adhesive being coextensive in area with the disc of liquid resistant material. As will be understood, the adhesive stratum is intended to act not only as a cement, but also as a waterproof, non-absorbent, gas impervious medium for avoiding the possibility of the contents of a bottle getting between the facing disc and the material of the cap, either the metal shelf itself or a cushion disc of cork or composition cork.

Furthermore, when using superimposed strips of the facing material and of adhesive tissue, it was essential, to bond the adhesive tissue to both the material of the cushion disc in the cap and the facing material.

In preparing the rolls of facing material and adhesive tissue, the practice usually followed was to form a roll of the tissue in strips of the desired width, and to unwind this roll and a roll of the facing material while feeding the two strips one over the other into the disc forming and assembling machine. This is a troublesome and expensive operation, because of the frequent breakage of the adhesive tissue and the necessity for using fairly heavy tissue to minimize this tendency. This is due partly to the fact that the facing material was substantiallly non-elastic, while the adhesive tissue possessed a certain degree of elasticity, thus introducing a factor of difficulty in securing a uniform paying of both the facing strip and the gutta percha tissue strip.

It is desireble, in the use of facing discs of the character above referred to, that the adhesive stratum be as thin as possible, and yet be continuous throughout the entire area of the facing disc, and particularly that it be uninterrupted about the edge of this disc, since at this point the disc should be firmly bonded so as to effectively seal the joint about the edge of the facing disc. When cutting and applying the discs of material and adhesive, there is no means of ascertaining whether the desired conditions are present in the completed cap. Consequently, there is always likelihood of imperfectly faced caps being produced.

With the above conditions in mind, I have provided material, in strip form, for facing bottle caps, in which one surface of the strip is provided with a firmly adherent, continuous thin facing of adhesive, thus avoiding all necessity for assembling strips of facing material and of adhesive tissue preparatory to their use in the bottle cap facing machine, and all of the disadvantages growing out of this practice.

In the strip material of my invention, a very thin stratum of adhesive is evenly distributed upon one face of a strip of facing material. The adhesive is not only firmly bonded to this material, but has a smooth surface finish of sufficient thickness to form the desired firm bond between a disc cut from the strip and the material of the cap to which such disc is cemented.

Furthermore, adhesive tissue must be of a thickness to have sufficient inherent strength to permit of its being stripped from a roll in a

mill for working same, and to admit of its being cut to the desired width and to be handled in the winding and the disc applying machines, and during the process of its production it has more or less of a longitudinally extending grain, as distinguished from its normal granular formation.

In the application of heat, when bonding the facing material to the cap, when utilizing adhesive tissue, a tendency of the adhesive is to break up into slightly isolated, small globules, thus interrupting the continuity of the bonding stratum. Whether this is due to irregularities in the surface of the facing strip, or to a shrinkage of the adhesive tissue when fused, I have been unable to determine. In the strip of my invention, however, the adhesive is thoroughly distributed throughout one face of the facing material, and the above conditions do not develop in the subsequent handling of the strips.

It is an object of the present invention to provide a method of producing spot center crowns such that the spots are easily and economically secured to the sealing discs and such that they are firmly secured and not liable to become loosened in use.

With these general objects in view the invention consists in the method which will be first described and then more particularly pointed out in the claims.

According to the method of the present invention, the strip material having a surface which is substantially non-absorbent and gas impervious, such as metal foil, is coated with a substance that is devoid of tackiness when dry and has adhesive qualities when soft. In carrying out the method according to what is considered the best practice the adhesive substance is such that it can be applied cold, i. e. at room temperatures, and is waterproof or insoluble in cold water. While various materials may be used I have found a suitable adhesive in a solution of dammar gum and rosin in mineral spirit or turpentine, to which is added 5% or less of a vegetable oil such as soya bean or China-wood oil. The dammar gum and rosin may be in the proportion of 35% to the whole. The adhesive may have a drier of lead resinate or the like in a proportion of 2% or less. This adhesive is waterproof and is not weakened by gases or acids, such as are present in the bottle contents with which crown caps are usually employed.

While the coating may be applied to the material in various ways, it is conveniently applied in fluid form and cold to a strip of foil from which the spots are to be cut. So far as the method of producing the strip is concerned, it is such that the effective distribution of the adhesive throughout the entire area of the facing material is assured, and this condition cannot be disturbed as a result of the cutting of discs from this material when in strip form. Furthermore, the adhesive surface may be thoroughly inspected while producing the strip material, so that any imperfect product may be discarded before it reaches the disc applying machine. In this connection it is noted that the spots may be conveniently assembled by feeding a strip of material over successive crown corks and cutting out a disc which is deposited on a cork, such assembling machinery being known in the art.

After the coating is applied to the metal foil it is dried. While this may be effected by air drying at room temperature it is more rapidly accomplished at a temperature of about 300° F. maintained for about 3 minutes. When dried the coating is devoid of tackiness so that the metal foil may be handled without difficulty or trouble. This is particularly advantageous when the metal foil is to be fed in strips because the application of the adhesive is carried out independently of the assembling steps. Moreover, the coating gives the thin metal foil more or less body which facilitates feeding and cutting. Since the adhesive is applied directly to the surface of the facing or spot material and firmly bonded thereto, there is no likelihood of difficulties arising as a result of separation of the adhesives from the facing strip during the spot forming operation, either as a result of poor adherence or from suction or otherwise, such as frequently occurs when using superimposed strips of facing material and of adhesive tissue. Moreover, in handling this material the adhesive stratum is incapable of stretch or distortion relative to the spot strip as frequently occurs in the handling of separate strips of adhesive tissue and facing material where any stretch or distortion of the adhesive stratum results in a defective cap and when the stretch is extreme, tearing of the adhesive tissue makes necessary the stoppage of the cap machine until the strip can be repaired.

After the coating is dry, the metal foil spots are assembled, coated side down, with the sealing discs. In case the metal foil is fed in a strip, spots may be cut out and deposited on the sealing disc, as above set forth.

At the time of assembly the coating material is softened to render it adhesive and the assembled unit is subjected to pressure. In carrying out the invention according to what is now considered the best practice the coating will be softened by heat after the crown is assembled. In cutting discs from this improved laminated strip having an adhesive stratum bonded thereto, there is no tendency toward mutilation of the adhesive layer by reason of possible drag of the cutting dies, and each disc, as delivered from the die to within a cap, will present a continuous uninterrupted adhesive surface upon the disc so as to insure, by the subsequent application of heat and pressure, a bond between the disc and the cap cushion layer coextensive in area with the disc.

This possibility of securing a clean cut by the dies for forming the discs, both as to the non-absorptive and gas impervious, and as to the adhesive stratum, insures an effective bond entirely about the edge of the spot or disc, thereby presenting a continuous barrier of non-absorptive and gas impervious material at the space between the disc and the cap which will effectively prevent the seepage of gas or fluid in a bottle between the disc and the portion of the cap to which it is applied.

Although the adhesive facing is sufficiently thick to provide an adhesive stratum or layer, it is sufficiently thin to avoid any tendency toward the expression during the application of pressure of any of the adhesive from between the facing material and the portion of the cap to which it is applied. This may be accomplished in any suitable manner, as by a heated plunger or a plunger and heated table. The heat softens the coating and renders it adhesive and the pressure serves to unite the metal foil spot to the cork.

Referring to the accompanying drawing, there is shown suitable mechanism for coating the strip and for cutting discs therefrom and adhesively

uniting the disc to caps at the time of the assembly of the discs with the caps. In the drawing,

Figure 1 is a diagrammatical view showing the coating of the strip.

Figure 2 is a longitudinal sectional view of a fragment of the strip.

Figure 3 is a side elevational view partly in section showing one step in the assembly operation.

Figure 4 is a view similar to Figure 3 showing the spot as it is cut and adhesively united to the cap at the time of assembly.

Figure 5 is an interior face view of the completed cap, and

Figure 6 is a cross sectional view of the cap shown in Figure 5.

The strip of facing material should have the characteristic of aluminum foil. That is to say, it should present one surface which is non-absorbent and gas impervious. This strip may be fed from a reel 10 to a reel 11, suitably separated so that the adhesive coating may be applied and hardened between the time any portion of the strip leaves the reel 10 and is wound upon the reel 11. For the purpose of applying the adhesive, the same may be maintained in a trough 12, positioned beneath an adhesive applying roll 13, between which and a roll 14, the strip passes, so that as the rolls are rotated the adhesive is applied to the undersurface thereof. As will be understood, the adhesive hardens between the time it is applied and the winding of the laminated strip upon the reel 11.

The completed spot material or liner is illustrated in Figure 2, and comprises the layer 15 of non-absorbent and gas impervious material, such as aluminum foil having on one surface the coating 16 of adhesive, which is preferably of the character hereinbefore described. This adhesive is waterproof or liquid resistant, and will be normally hard, i. e. non-tacky, at room temperature so that the material may be conveniently handled in strip form, but quickly softens under the application of heat, becoming tacky, so that upon the application of pressure, the laminated disc will be adhesively retained in the cap. The preferred method of applying the material to the cap is to utilize, at the time of assembly, both heat and pressure to unite the spot to the cork or cushion material insert or facing of the cap.

In Figures 3 and 4, there is shown a suitable mechanism for applying the disc and adhesively uniting it to the cork insert at the time the strip is punched from the disc and assembled with the cap.

The cap 17 is of the conventional crown type having an interior facing 18 of cushion material, such as composition cork retained in the cap as by an adhesive layer 17'; the cushion disc and adhesive may be applied to the cap in any suitable manner, for example, as described in the patent to Mierse, No. 1,893,786, granted Oct. 10, 1933. The caps, with the cushion discs inserted therein, may be positioned beneath the cutting dies 19, 20, by means of a traveling bed 21 having suitable sockets for receiving the cap so as to position the same accurately beneath the cutting dies. The strip material for forming the spot is fed beneath the die 20 with the adhesive coating 16 facing the cap, and when the die descends it will cut from the strip, which is fed by any suitable means (not shown), a spot or facing 22 of the character illustrated in Figures 5 and 6. The spot or disc is preferably of smaller diameter than the cap facing so as to form a substantially centrally disposed spot which leaves around its edge an exposed portion of the cushion material adapted to engage the edge of a bottle neck, the spot being of sufficient size to close the bottle mouth and prevent contact of the contents with the cushion material.

As will be observed (Figures 3 and 4) as the punch 20 descends, it cuts from the strip a spot of the size shown in Figure 5, and continued downward movement presses this disc upon the cushion layer 18.

The punch 20 may be maintained at an elevated temperature, as by means of a burner 23, and the temperature should be sufficient to fuse or soften the adhesive coating and make it tacky so that, at the time the disc is assembled with the cap, the heat and pressure will cause the disc to be adhesively united to the surface of the cushion material with sufficient permanency to insure that the position will be retained and avoid likelihood of displacement of the disc thereafter.

The assembled unit is then permitted to cool and the cooling may advantageously be coupled with pressure, for example, by a plunger. Cooling may be effected in any suitable manner, being carried out to the congealing point of the coating material.

The resulting crown has a firmly secured metal foil spot which is not liable to become loose in use owing to the fact that the adhesive substance is not soluble in liquids more commonly sealed by crown corks. Moreover, when the metal foil is assembled with the sealing disc it is already prepared for being stuck in place, the sticking being accomplished by the simple application of heat and pressure. The coating operation is a simple one and the coated metal foil is easily handled because the dry coating is not tacky.

A cap made in accordance with this method possesses the advantage of a substantially uniform and complete distribution of the adhesive layer throughout each spot or facing disc. The method has the advantage of eliminating the labor of associating a separate adhesive strip and a strip of facing material, and the further advantage of enabling higher speeds to be maintained in the facing spot applying machine. The elimination of the danger of breakage of a separate adhesive tissue strip avoids the frequent stoppage of the machine, which was unavoidable due to the handling of the somewhat fragile and elastic adhesive tissue.

What is claimed is:

1. The improved method of manufacturing caps of the type having an interior disc of cushion material provided on its exposed face with a center spot, which comprises providing spot material in strip form having one surface formed of an exposed continuous coating of water resistant adhesive which is normally hard at room temperature but becomes tacky upon the application of heat and having another surface to be exposed to the contents of a capped container, cutting from said strip a facing spot having one surface completely coated with said adhesive with a cap disposed beneath the portion of the strip from which the spot is cut, whereby the cutting operation positions the spot upon the cushion material with the coating between the spot and the cushion material, and upon assembly applying simultaneously to the spot pressure and sufficient heat to render the adhesive tacky, thereby causing the spot to adhere to the cushion ma-

GGG/37

terial, and thereafter permitting the adhesive to cool and harden.

2. The improved method of manufacturing caps of the type having an interior disc of cushion material provided on its exposed face with a center spot, which comprises providing metal foil spot material in strip form having one surface formed of an exposed continuous coating of water resistant adhesive which is normally hard at room temperature but becomes tacky upon the application of heat and having another surface to be exposed to the contents of a capped container, cutting from said metal foil strip a facing spot having one surface completely coated with said adhesive with a cap disposed beneath the portion of the strip from which the spot is cut, whereby the cutting operation positions the spot upon the cushion material with the coating between the spot and the cushion material, and upon assembly applying simultaneously to the spot pressure and sufficient heat to render the adhesive tacky, thereby causing the spot to adhere to the cushion material, and thereafter permitting the adhesive to cool and harden.

3. The improved method of manufacturing caps of the type having an interior disc of cushion material provided on its exposed face with a center spot, which comprises providing spot material in strip form having one surface formed of an exposed continuous coating of water resistant adhesive which is normally hard at room temperature but becomes tacky upon the application of heat and having another surface to be exposed to the contents of a capped container, cutting from said strip a facing spot having one surface completely coated with said adhesive with a cap disposed beneath the portion of the strip from which the spot is cut, whereby the cutting operation positions the spot upon the cushion material with the coating between the spot and the cushion material, and upon assembly applying simultaneously to the spot pressure and sufficient heat to render the adhesive tacky, thereby causing the spot to adhere to the cushion material and thereafter permitting the adhesive to cool and harden while subjecting the assembled unit to pressure.

4. The improved method of manufacturing caps of the type having an interior disc of cushion material provided on its exposed face with a center spot, which comprises providing metal foil spot material in strip form having one surface formed of an exposed continuous coating of water resistant adhesive which is normally hard at room temperature but becomes tacky upon the application of heat and having another surface to be exposed to the contents of a capped container, cutting from said metal foil strip a facing spot having one surface completely coated with said adhesive with a cap disposed beneath the portion of the strip from which the spot is cut, whereby the cutting operation positions the spot upon the cushion material with the coating between the spot and the cushion material, and upon assembly applying simultaneously to the spot pressure and sufficient heat to render the adhesive tacky, thereby causing the spot to adhere to the cushion material, and thereafter permitting the adhesive to cool and harden while subjecting the assembled unit to pressure.

UNITED STATES PATENT OFFICE.

CHARLES E. McMANUS, OF NEW YORK, N. Y.

BOTTLE-CAP-MAKING MACHINE.

1,402,780. Specification of Letters Patent. Patented Jan. 10, 1922.

Application filed April 15, 1916. Serial No. 91,278.

To all whom it may concern:

Be it known that I, CHARLES E. McMANUS, a citizen of the United States, residing at the borough of Manhattan, in the city, county, and State of New York, have invented certain new and useful Improvements in Bottle-Cap-Making Machines, of which the following is a specification, reference being had therein to the accompanying drawings, which form a part thereof.

My invention relates to bottle cap making machines and more particularly to a machine adapted to apply a protecting disk to the resilient disk for a cap.

It is desirable in producing bottle caps for most uses, to provide the resilient disk formed of cork or other material, with a non-absorbent, gas impervious protecting facing disk so that when a cap is applied to a bottle, this facing extending across the neck of the bottle, will protect the resilient disk from the action of the liquid and gases within the bottle and at the same time prevent the contamination of the contents of the bottle by contact with the material of said resilient disk, or the formation of gas vents through the disintegration thereof. This protecting facing also prevents particles of the material of the resilient disk falling within the bottle.

My invention contemplates a machine for applying protecting facing disks to the resilient disks used in bottle caps, the machine being so constructed as to adapt it to the rapid and automatic application of the facing disks to the resilient disks, in a manner to secure a sufficiently tight bond between the two to ensure that permanency in the relation of parts necessary to a satisfactory sealing of a bottle by the application of the cap thereto.

In a machine made in accordance with my invention, it is necessary to combine in the structure, means whereby a damping fluid may be applied to that area of the surface of the resilient disk to which the facing disk is to be applied; means for pressing the said facing disk into the necessary intimate engagement with the resilient disk to secure the required bond between the facing disk and said resilient disk, the feeding means by which the facing disk is brought into the proper relation to the pressing mechanism, and the resilient disk, and feeding means by which the succeeding resilient disks are brought rapidly into that position in which the facing disks are applied thereto.

I have found it desirable to limit the application of the damping fluid to an area of the resilient disk, substantially coinciding with the area of the facing disk to prevent discoloration of the resilient disk by the said damping material particularly when the protecting facing disk is of a diameter less than that of the resilient disk. Preferably in caps of this character a facing disk of less diameter than the cork or other disk, is used, since it is desirable to have the neck of the bottle sealed directly against the cork disk or other cushion, to avoid possibility of the formation of gas ducts as a result of a buckling or wrinkling of the material of the protective facing disk. In order to satisfactorily apply this small facing disk to the resilient disk of a bottle cap, I have found it necessary to so construct the machine as to secure substantial exactitude in the centering of the protecting disk with relation to the cork or other resilient disk, and to provide means whereby the facing disk will be applied in a manner to avoid its shifting upon the withdrawal of the presser rod, or subsequently thereto, before the adhesive has had an opportunity to properly set. To secure the desired rapid feeding of the protecting disks, I prefer to cut these disks from a continuous strip or web of previously gummed material, each disk being cut from this strip immediately preceding its application to the resilient disk. The presser mechanism is so constructed as to successively cut a disk from said strip or web, and apply the disk so cut to the resilent disk of a bottle cap by a continuous movement of the presser rod while affording a sufficient dwell, subsequent to the initial application of the disk to the resilient disk, to ensure a sufficiently tight adhesion of the facing disk to the resilient disk to permit withdrawal of the presser rod and the subsequent feeding movement of the resilient disk.

A machine made in accordance with my invention as shown in the drawings also provides means in conjunction with the presser mechanism for centering a bottle cap with relation to the presser bar prior to the application of the facing disk, so as to ensure substantial accuracy in the

centering of the facing disk upon the resilient disk of the cap. I also provide in the machine shown means for holding the severed disk firmly against the presser rod until it has been applied to the resilient disk for the purpose of ensuring a substantially parallel relation between the cut disk, the operative face of the presser bar and the face of the resilient disk to which the disk is to be applied. I also provide in the machine shown, means whereby the feeding mechanism for the paper strip or web will be automatically made inoperative in the event that a resilient disk is not fed in a timely manner with relation to the presser mechanism.

I also provide in the machine, means whereby after the resilient disk with the protecting facing applied thereto, leaves the presser rod, it will be maintained under pressure for a sufficient interval to ensure the requisite setting of the binding agent while the facing disk is held firmly upon the resilient disk.

The invention consists in the novel features of construction and combination of parts hereinafter set forth and described and more particularly pointed out in the claims hereto appended.

Referring to the drawings:—

Fig. 1 is a plan view of a machine embodying my invention;

Fig. 2 is a longitudinal section through the machine;

Fig. 3 is a vertical section through the presser and disk cutting mechanisms;

Fig. 4 is a vertical section through the damping mechanism;

Fig. 5 is a perspective view of the strip feeding, presser and disk cutting mechanisms, and Fig. 6 is a detailed view of the presser bar mechanism, and appurtenant parts.

Like letters refer to like parts throughout the several views.

In the accompanying drawings, I have illustrated my invention in connection with a machine wherein the resilient disk is assembled with the metal cap prior to the application of the protecting facing disk thereto, although the essential features of my invention may be utilized with equal facility to the application of said protecting facing to the resilient disk prior to its assembly with the metal cap. In the following description, I will refer more particularly to the specific embodiment of my invention shown in the drawing, it being understood, however, that this particular mechanism may be modified in those respects necessary to ensure the feeding of a cork or other resilient disk alone, without departing from the spirit and scope of the invention.

In the form of the invention illustrated in the drawings, I have shown at 10 a channeled track or run-way along which the previously assembled caps are intermittently fed in any desired manner, as by means of an ordinary tongue bar 11 receiving a four way movement from any desired source of power. The means for imparting this four way movement to the tongue bar 11 comprises the disc 11^a driven from the shaft 15 by means of the intermeshing gears 11^b and 11^c, and an arm 11^d carried by said bar 11, and pivotally mounted eccentrically of the disc 11^a, all as indicated in dotted lines in Fig. 1 of the drawings. This construction is old and well known in this art and any other desired means of imparting the desired movement to the tongue bar 11 may be used. A suitable mechanism delivers the caps to which the facing is to be applied, to the track or runway 10, this delivery mechanism in the accompanying drawings consisting of a rotating disk 12 upon which the caps are successively delivered from a runway 13 leading from a storage hopper not shown. The rotary movement of the disk 12 will hold the caps against its peripheral rim 14 and cause a circular movement of the caps so as to ensure the timely feeding thereof to the track or runway 10 and within the operative field of the tongue bar 11. Extending longitudinally of the machine, is a power shaft 15 by means of which movement is imparted to the various mechanisms in the machine, thus synchronizing the movement of such mechanisms.

Arranged in operative relation to the said track or runway 10 and the feeding mechanism 11, are a damping mechanism adapted to apply a damping medium adapted to react upon the gum upon the protecting facing disk, and a presser mechanism adapted to force such a disk to place and hold it until the binding material has been sufficiently set to permit the further treatment of the article. These mechanisms are arranged successively and their operations are so timed as to be effective during that interval when the feeding mechanism 11 is inoperative in relation to the caps, or when the cork or other disks are treated before their application to the metal caps, to the disks alone. In the form of the invention shown, I associate with the presser mechanism a strip or web feeding mechanism and a cutting mechanism, the presser bar of said presser mechanism serving as a punch in cutting disks from said web.

The damping mechanism above referred to in the form of the invention shown comprises a tank 16 having a delivery nozzle 17, the discharge end of which is provided with a distributing pad 18 having the two-fold function of retarding the flow of the damping medium and applying the same over a restricted area in a film sufficiently thin to avoid excess moisture upon the cork or other

resilient disk. This pad offers sufficient resistance to the flow of the damping medium and is of sufficient bulk, to ensure the distribution of the damping medium mainly by capillary attraction. To ensure reliability in the feeding of the damping medium as well as to define the maximum pressure of the pad 18 upon the cork, or other disk, the nozzle 17 is made movable in relation to the tank 16, and is subjected to a thrust toward the track or runway 10 from a coiled spring 19 seated about a reduced discharge nozzle 20 upon the tank 16 and acting against a cup-like head 21 carried by the nozzle 17. This head 21 is slidably mounted within an annular ring 22 carried by the tank 16, thus forming a substantially water-tight joint about the top of the said head. By this construction the ordinary feeding of the damping fluid or medium will be through capillary attraction but upon the reciprocation of the nozzle 17 subsequent to its contact with the cork or other disk, there will be a forced feed due to the conditions between the cup 21 and the bottom of the tank 16. This forced feed will have the effect of causing a slightly greater quantity of the damping fluid to be delivered to the disk directly below the outlet of the nozzle 17 than about the edge thereof and will also have the effect of ensuring the constant presence of sufficient damping medium in the pad 18 to permit the operation of the machine at the desired speed.

In the form of the invention shown in the drawings, the tank 16 and all of its appurtenances are mounted upon a reciprocatory slide 23 mounted in suitable ways upon the frame of the machine and actuated by means of the connecting rod 24, the eccentric 25 and the strap 26. To avoid possibility of the displacement of the cork or other disk or of the metal cap carrying the same upon the withdrawal of the pad 18, I provide in the form of the invention shown, a guard plate 27 having an opening 27ª therethrough, above the track or runway 10 through which opening the pad 18 passes.

Beyond the tank 16 and alined longitudinally of the track or runway 10 with the pad 18 is a reciprocatory presser rod 28 adapted to force the facing disk into engagement with that portion of the resilient disk of a bottle cap which has been previously moistened by means of said damping pad. The said rod 28 is spaced from the damping pad 18 sufficiently to permit the conditioning of the dampened portion of the surface of the resilient disk so as to receive the said facing disk. The rod 28 is carried by and reciprocates with, a slide 29 mounted in suitable ways in the frame of the machine, and actuated by a connecting rod 30, eccentric 31 and strap 32.

In the form of the invention shown, the facing disks are cut from a gummed strip or web A just prior to the application of said disk to the cork or other resilient disk, of the cap. To permit this operation, I mount above the track or runway 10, a female part 33 of a cutting die, a tubular guide 34 being mounted upon said die part and spaced away therefrom, as shown, sufficiently to form a slot through which the gummed strip or web passes. The presser rod or bar 28 is slidably mounted in said guide 34, the bore of said guide being alined with the die opening in a manner to secure the desired shearing effect upon the strip or web with the depression of said presser bar. The lower end of the bar 28 is faced off so as to secure the desired sharpness of edge.

Extending laterally of the machine adjacent the parts 33 and 34 and alined with the top of the die part 33 is a track 35 in which is slidably mounted a carriage 36 carrying a spring pressed gripper member 37 by means of which the strip or web may be intermittently fed in relation to the disk applying mechanism, the strip A being supported upon a suitable reel 38. The track 35 is provided with suitably flared-plates 39 to guide the web in relation to the gripper mechanism. I also provide a check spring 40 for preventing a return movement of the strip or web with the said gripper mechanism. The reciprocatory gripper 37 is actuated by means of a lever 41 actuated from an eccentric 42 and strap 43 carried by the shaft 15.

To prevent the feeding of the strip or web, except when a cork or other resilient disk is in a position to have a facing disk applied thereto, I mount upon the track 35 a lever 45 one end of which is provided with a weight 46 having a finger 47 adapted to bear upon the edge of the cap, or of the resilient disk, as the case may be. Pivotally mounted upon the tracks 35 adjacent the carriage 36 is an elongated block 48 having a weighted extension 49 adapted to be engaged by the end of said lever 45. The said block 48 co-operates with a bearing pin 50 upon the gripper member 37, so that when the weight 46 is raised by the engagement of the finger 47 thereon with a cap or resilient disk, the block 48 will drop away from the pin so as to permit the gripper 37 to operatively engage the strip or web; but in the event that the weight 46 is permitted to drop, said block 48 will be projected within the path of said pin 50 and thus prevent the operative engagement of said gripper member and the feeding of the web when no resilient disk is in position with relation to the presser mechanism. The specific strip or web feeding mechanism above described is not material to my invention, and other means for intermittently feeding the strip or web and preventing feeding movement thereof when no resilient disk is in position to have the facing disk applied

thereto, may be substituted therefor without departing from the spirit and scope of the invention.

The presser bar or rod 28 has extending longitudinally therethrough, a small duct 51 by means of which a suction may be applied to the paper web while the disk is being cut therefrom and to the disk after it has been so cut, so as to prevent such a displacement of the disk as will prevent its being applied perfectly flat to the cork or other resilient disk. Surmounting the rod or bar 28 is a cup 52 operating within which is a pump plunger 53 which is supported in a fixed relation in the frame of the machine by a bracket 54. The cup 52 being mounted upon and movable with the rod or bar 28 and connected with the interior thereof through the short duct 55, it will be observed that with the downward movement of said bar there will be a substantial reduction of the pressure in the cup 52 and duct 51 and that with the reversal of this movement, there will be a corresponding increase of pressure thus tending to avoid displacement of the disk upon the return movement of the rod or bar 28. In the form of the invention shown, the plunger 53 is so set with relation to the cup 52 that at the end of the stroke of the rod or bar 28, said plunger will pass from said cup and thus admit air thereto. The cup 52 may be so proportioned, if desired, as to admit air thereto substantially simultaneously with the application of the facing disk to the cork, or other resilient disk, so as to increase the effective pressure upon the return stroke thereof.

After the tongue bar 11 has fed a disk below the die part 33, it is essential to secure substantial accuracy in the centering of the cap, or the cork or other disk, with relation to the opening in said die member in order to have the disk applied to the area of said cork, or other disk, which has been previously dampened by the pad 18. In the form of the invention shown, this means for centering the cork, or other disk, is so constructed as to be applicable to a machine for applying the facing disk after the cork or other disk has been assembled in the metal cap. It comprises an annular wedge 56 carried by a ring 57 mounted in the lower face of the die part 33. Carried by said rim 57 are a plurality of rods 58, a head ring 59 being provided for all of said rods 58. Mounted upon the rod or bar 28 is a collar 60 adapted to engage the end of the several rods 58 and impart a reciprocatory movement to the wedge 56 just prior to the application of the facing disk to the cork or other disk. By this construction, clearance beneath the ring 56 for the feeding of successive caps is provided and the ring [illegible] rod or bar 28 and the facing disk [illegible] thereby will have simultaneous movement [illegible] so as to avoid likelihood of the displacement of said disk just prior to its application to the cork or other resilient disk. The springs 58ª will have the function of withdrawing the wedge 56 prior to the succeeding feeding movement of the cap.

When applying the facing disk, it is also necessary to prevent oscillatory movement of the cap upon the anvil 61 positioned below the opening of the die part 33, the surface of the cap engaging said anvil being convex, and it being impossible to provide upon said anvil, supports extending longitudinally of the track or runway 10 for the edges of said cap. To impart the desired stability to the cap, I provide the lower face of the die part 33 outside of the ring 56 with fixed abutments 62 which will engage the top of the out-turned rim of the cap and prevent any oscillatory movement in a direction longitudinally of the track or runway 10. The anvil 61 may be supported from the track 10, or from any other adjacent portion of the machine frame.

To avoid movement of the strip or web A resulting from a drag thereupon while the disk is being cut therefrom, I mount a clamp member 63 upon a rod 64 slidably mounted in the slide 29, a spring 65 being seated between said clamp member and said slide in a manner to give the desired cushioning effect when the clamp member is pressed against the track 45 while developing sufficient pressure to secure the desired operative effect upon the strip or web.

The rod 64 may be adjusted with relation to the slide 29 and the plunger 53 may be adjusted with relation to its supporting bracket 54 to facilitate accuracy in the assembling of the machine or in the adjustment thereof to secure the desired operative conditions.

I have found it preferable to use a facing disk, the diameter of which is substantially less than that of the cork or other resilient disk; since I have found that a better sealing of the neck of the bottle is secured when the top of the bottle seats directly upon the cork or other resilient disk. By better sealing I refer not to greater permanency in any particular case, but to greater uniformity in the effectiveness of the seals in a large number of cases, for, to use the trade expression, the percentage of "leakers" has been materially reduced where this type of facing has been used. With the smaller facing disk, however, I have encountered difficulties in the mechanism for applying these disks, due to the necessity for having the disk positioned with sufficient accuracy in relation to the setting of the cork or other disk to avoid possibility of a portion of the facing disk engaging the top of the bottle in a manner to form a leak about the edge of the disk, I have found in applying these smaller disks that there is a tendency for the facing disk

to shift slightly upon the cork, or other, disk before the binding material has been properly set and this difficulty has necessitated the incorporation in a machine made in accordance with my invention and adapted especially to apply these smaller disks, of means for preventing such movement of the facing disk.

In the form of the invention shown, I prevent this shifting by forcing small portions of the facing disk, at the edge thereof, into the body of the cork, or other disk, sufficiently to prevent movement of the disk in relation to the cork, without, however, cutting or mutilating the cork or other disk in any way. I also provide means whereby while the facing disk is held in position, by being forced into the body of the cork slightly, it will be subjected to a continuing pressure sufficient to permit the binding medium to set enough to permit the withdrawal of the presser rod or bar and the subsequent application to the facing disk of further pressure for insuring permanency in the bond between the two disks.

To accomplish the results above referred to, I provide the lower end of the rod or bar 28 with a plurality of divergently arranged arms 66 each having at the outer lower edge thereof an edged prong 67 coinciding with the outer surface of the said plunger. The bar 28 is hollow from end to end and slidably mounted therein is a stem 68 through which the duct or opening 51 passes. The lower end of this stem carries a platen head 69 the edge of which is provided with a plurality of slots to accommodate the arms 66. The rod or bar 28 is provided with a stop shoulder 70 co-operating with a flanged head 71 upon the inner end of the stem 68 in a manner to limit the outward movement of the platen head 69 under the control of the spring 72 seated within the upper portion of the rod or bar 28 and acting against a plug 73 within said rod or bar. To permit the setting of the platen head with relation to the arm 66, the flanged head 71 is adjustably mounted upon the stem 68 and the plug 73 is adjustably mounted in the rod or arm 28 so that the pressure exerted upon the said platen upon the facing disk may be regulated. The plug 73 has an opening longitudinally therethrough of substantially the same diameter as the duct 51 so as to permit the application of the required suction to the center of the platen head 69. When the device is assembled, the head 69 will be spaced away from the portion of the rod or bar 28 between the arms 66 sufficiently to permit the required movement of the said head.

From the foregoing it will be observed that in a machine made in accordance with my invention as shown in the accompanying drawings, the reciprocatory presser bar embodies therein a yieldable platen adapted to exert a continuing pressure upon the facing disk, and prongs fixed in relation to the presser bar adapted to engage the edge of the facing disk while pressure is being applied thereto, said prongs upon the reversal of the movement of the pressure rod or bar being disengaged from the said facing disk while the platen is still in engagement therewith.

I have found the above characteristics to be important where a facing disk of a diameter less than that of the cork or other resilient disk, is used and where it is necessary to apply the facing disk to the cork or other disk while the gum thereon is drying; since a certain dwell is essential in order to permit the damping medium to act upon this gum in a manner to make the gum adhesive and permit it to set sufficiently to hold the facing disk with the necessary permanency to permit subsequent treatment of the faced disk.

Receiving the caps from the track or runway 10 is a rotary table 75 having adjacent the edge thereof a sequence of spring clamps 76 adapted to be controlled by a cam 76ª so that as each cap containing the facing disk is delivered to said table, it will be received by one of said clamps and be subjected to a continuing pressure therefrom during the greater portion of one rotation of said table. This table is substantially like that used in the ordinary assembling machine for bottle caps and a detailed description thereof is therefore unnecessary. The sole function of the spring clamps upon said table, in connection with the machine made in accordance with my invention, is to insure a sufficient dwell after the application of the facing disk to the cork or other disk, to permit the setting of the adhesive or binding medium prior to the delivery of the finished article. This binding medium will set readily at normal temperatures, although if desired heat at a low temperature may be applied to the table to expedite the evaporation of the damping medium. I have, however, found it desirable to have said binding medium set under pressure in order to secure the desired intimacy of the bond and to cause the facing strip to be perfectly flat.

In connection with the table 75 I provide an ordinary collecting belt 77 for the purpose of facilitating the inspection of the finished article.

The waste of the strip or web A is merely allowed to run from the machine and may be collected in any desired receptacle.

The strip A may be made of any desired material, one side thereof being water proof, gas impervious and acid resisting, while the other side thereof is provided with a gummed surface. The strip must be thin to avoid its projecting from the cork or other resili-

ent disk and interfering with the sealing of the bottle, and sufficiently pliable or flexible to permit it to yield readily with the cork or other disk. If the material of the disk does not possess inherent properties to make it non-absorbent, gas-impervious and acid resisting, it may be treated in any desired manner to impart to its these properties. It will be readily observed that the strip or web A must be dry when the disks are cut therefrom, since the application of a wet adhesive to the surface thereof prior to the cutting of the disks therefrom would not only interfere with the shearing action but would foul the cutting mechanism so rapidly as to make the machine impracticable.

The operation of the herein described machine is substantially as follows.

A machine made in accordance with my invention is designed merely to place a protecting facing disk upon a cork or other resilient disk, entering into the structure of a closure cap for bottles and is not adapted to assemble the cork or other disk with the metal part of the cap, whether the facing disk be applied to the cork or other disk before or after it has been assembled in the completed article. The machine of my invention might be associated with an assembling machine so as to produce a cap having a protecting facing but the variance in time required to assemble the cap, and to apply the protecting facing thereto is such as to ordinarily make it desirable to operate these two types of machine entirely independently of each other.

In the form of the invention shown the protecting facing disk is applied after the cork or other resilient disk has been assembled with the metal part of the cap, and the details of the machine are so constructed as to adapt the machine to the handling of the assembled caps.

The caps to be faced are successively delivered at the desired rapidity by the delivery mechanism to the intermittently operative feeding mechanism 11, by which they advance with a step by step movement toward the damping and the presser mechanism. During the dwell of the caps between their feeding movements, the tank 16 and the rod or bar 28 are simultaneously forced downwardly into the operative relation with certain of the caps, this movement applying the facing disk to one cap, and damping the cork or other resilient disk, of a succeeding cap so as to condition it to receive the facing disk upon a subsequent operation of the machine. Since the several operations of the dampening of the cork or other resilient disk, the strip from which the facing disks are cut, and cutting and applying the disk are substantially simultaneous, I will, to avoid confusion in the description, describe each operation separately.

As to the damping mechanism, since the pad 18 retards the flow of the damping medium, it is necessary to secure the desired damping effect upon the cork or other disk by applying said pad 18 to the disk with sufficient pressure to force the damping medium in the desired volume through said pad. As the tank 16 and its appurtenances descend, the pad 18 will contact with the cork or other disk, and with a subsequent and continuing movement of the said tank, the spring 19 will yield under the pressure sufficiently to permit the head 21 to move toward the bottom of the tank and thus tend to force the damping medium contained in said head and in the opening through the nozzle 17, into and through the pad 18 in a manner to deposit a thin film of the medium upon the surface of the cork or other disk. With the reversal of the movement of the said tank, however, the pad will remain in contact with the cork or other disk and as the tank recedes the head 21 will have the two-fold effect of instantly retarding the flow of the damping medium toward the pad, and of drawing a fresh supply of the said medium within the head 19 from the tank 16. The forced feed of the damping medium after the application of the pad 18 to the cork or other disk, will cause the greatest volume of the damping medium to be adjacent the center of the pad 18 and the dwell of this pad during the first part of the return movement of the tank, will have the effect of equalizing the quantity of the damping fluid throughout the entire area to which it is applied, and limiting this quantity to a thin film.

The damping medium used may vary as to its composition according to the composition of the gum used upon the strip or web A from which the facing disks are cut, or if composition disks are used instead of cut cork disks, with the character of the binder as well as the gum, so as to ensure any desired chemical reaction which will facilitate the quick adhesion of the facing disk to the cork or other disk and permanency of the bond between the two.

While a short track or runway 10 may be employed, I preferably space the damping mechanism sufficiently in advance of the presser mechanism to ensure the portion of the cork or other disk having the damping medium thereon being in a condition to receive the previously gummed facing disk as it approaches the presser mechanism.

As each cap is fed in relation to the damping mechanism, it passes under the guard plate 27 and is held thereby in a fixed relation to the pad 18.

After leaving the damping mechanism, the caps are successively fed in relation to the presser mechanism, being brought to rest below the opening in the die part 33, and

upon the anvil 61. As each cap approaches the die, the ring 56 is in its upward position so as to leave the proper clearance, and the upper rim of the metal part of the cap engages the projections 62 at diametrically opposite points thereof in the direction of the longitudinal movement of the cap, thus holding the cap firmly in place.

As each cap comes to place the carriage 36 is reciprocated, the gripper 37 thereon engaging the strip or web A which has the gummed surface thereof presented downwardly towards the said die part 33, and feeds said strip or web to an extent required to cut one disk therefrom. Upon the reversal of the movement of the carriage 36, the check spring 40 will prevent a return movement of the strip or web. In the event that at any time a cap is not fed beneath the said die part, the tongue 46 upon the weight 47 will meet no resistance, thus causing said weight to rock the lever 45 and force the block 48 into operative engagement with the pin 50 upon the gripper 37 in a manner to prevent said gripper feeding the strip or web.

During the first stages of the descent of the rod or bar the platen 69 and the arms 66 will act as a punch co-operating with the die part 33 to cut a disk from the strip or webs A. With the downward movement of said rod or bar the cup 52 will be moved in relation to the plunger 53 in a manner to develop a suction through the duct 51 upon the strip, thus holding the cut disk flat against the face of the said rod or bar; and this suction will continue during the entire downward stroke of the said rod or bar.

With a continued downward movement of the rod or bar 28, the collar 60 will engage the ends of the spring pressed rods 58 and force the ring 57 downwardly forcing the wedge 56 within the metal portion of the cap, which will center the cap with relation to the rod or bar 28 and will remain in this position until the facing disk has been applied to the cork or other disk, and prevent movement of the cap in relation to the rod or bar during this interval.

As the rod or bar 28 approaches the limit of its downward stroke, the platen 69 will force the facing disk, under a yielding pressure, upon the previously dampened portion of the cork or other disk, thus compensating for any variance in the thickness of the cork or other disk, limiting the pressure applied thereto, and permitting a dwell of the disk under pressure sufficient to ensure a temporary bond between the facing disk and the cork or other disk. As the platen 69 recedes against the tension of its spring 72, the prongs 67 will force divergent portions of the edge of the facing disk into the material of the cork, or other, disk in a manner to secure a firm bond at those points and thus not only ensure accuracy in the centering of the facing disk, but sufficient permanency in the bond to avoid slippage of the facing disk in relation to the cork or other disk. With the reversal of the movement of the rod or bar 28, the prongs 67 will be disengaged or withdrawn from the material of the cork, or other, disk while the platen 69 continues to apply pressure to the facing disk in a manner to prevent any possible displacement thereof. With this upward movement, the pressure in the cup 52 will be raised above atmosphere in a manner to serve somewhat as an injector for ensuring a clean separation of the platen 69 from the facing disk. It is apparent that by adjustment of the plug 73 the pressure exerted by the platen 69 may be regulated. The shoulder 70 and the plunger head 71 upon the stem 68 limit the outward position of the platen 69 and by adjusting said plunger head 71, the relative position of the platen 69 and the arms 66 may be regulated.

As the rod or bar 28 moves upwardly, the ring 60 will be disengaged from the spring pressed rods 58 permitting the ring 57 to recede within the lower face of the die part 33 and afford clearance for the subsequent feeding movement of the caps.

As the slide 29 descends, the clamp 63 will yieldingly engage the strip or web A in a manner to check any tendency of the strip to drag while the facing disk is being cut therefrom.

After leaving the presser mechanism, the cap is delivered to one of the spring clamps 76 carried by the table 75, which clamp will close upon the cap in a manner to apply a continuing pressure thereupon until the table 75 has turned to a point where the cap will be discharged upon the collecting belt 77. The table 75 need not be subjected to heat to secure the desired bond between the facing disk and the cork or other disk, it being merely required that the facing disk be subjected to a continuing pressure after its application to the cork or other disk, to secure the desired permanency of the bond between the two disks. If desired heat at a low temperature may be applied to the said table, solely for the purpose of drying out the damping medium, however.

The operations above described are either simultaneous or in such rapid sequence, as to be practically simultaneous, as the machine is operated at a fairly high speed. The feeding movement is alternated with the operations incidental to the application of the facing disk to the cork or other disk.

It is not my intention to limit the invention to the details of construction shown in the drawings or to the particular mechanical movements by which the dampening and presser mechanism are actuated. The machine shown in the drawings is adapted to

handle previously assembled caps, but it is apparent that to adapt the machine to handling the cork or other disks, before assembling them with the metal portion of the cap, would require merely the modification of the feeding and holding mechanisms for the disks and would not involve any substantial variance in the functions of the machine.

Having described the invention, what I claim as new and desire to have protected by Letters Patent is:—

1. A machine for making bottle caps embodying therein means adapted to apply a damping medium to a portion of the area of a resilient disk for a bottle cap, and means for applying previously gummed facing material to the portion of the disk to which said damping medium is applied.

2. A machine for making bottle caps embodying therein means adapted to apply a damping medium to a portion of the area of a resilient disk for a bottle cap, means for cutting a disk of facing material from a previously gummed strip, and applying said disk to the dampened portion of said other disk, and feeding means for said strip.

3. A machine for making bottle caps embodying therein means for applying a damping medium to the central portion of one side of a resilient disk for a bottle cap, means for cutting a facing disk of substantially the same area as the dampened portion of said resilient disk from a previously gummed strip and for applying said facing disk to said resilient disk, and feeding means for said strip.

4. A machine for making bottle caps embodying therein means for applying a damping medium to the central portion of one side of a resilient disk for a bottle cap, means for cutting a facing disk of substantially the same area as the dampened portion of said resilient disk from a previously gummed strip, said means embodying therein a platen adapted to press said facing disk into engagement with the resilient disk and means adapted to press portions of the edge of said facing disk into the body of said resilient disk whereby displacement of said facing disk upon the withdrawal of said platen therefrom is prevented and feeding means for said strip.

5. A machine for making bottle caps embodying therein means adapted to apply a damping medium to a resilient disk for a bottle cap, means for applying previously gummed facing material to the portion of the disk to which said damping medium is applied, and means subjecting said facing disk to a continuing pressure after it has been applied to said resilient disk.

6. A machine for making bottle caps embodying therein means adapted to apply a damping medium to a resilient disk for a bottle cap, means for cutting a disk of facing material from a previously gummed strip, and applying said disk to the dampened portion of said resilient disk, feeding means for said strip or web and means subjecting said facing disk to a continuing pressure after it has been applied to said resilient disk.

7. A machine for making bottle caps embodying therein means for applying a damping medium to the central portion of one side of a resilient disk for a bottle cap, means for cutting a facing disk of substantially the same area as the dampened portion of said resilient disk from a previously gummed strip and for applying said facing disk to said resilient disk, feeding means for said strip, and means subjecting said facing disk to a continuing pressure after it has been applied to said resilient disk.

8. A machine for making bottle caps embodying therein means for applying a damping medium to the central portion of one side of a resilient disk for a bottle cap, means for cutting a facing disk of substantially the same area as the dampened portion of said resilient disk from a previously gummed strip, said means embodying therein a platen adapted to press said facing disk into engagement with the resilient disk and means adapted to press portions of the edge of said facing disk into the body of said resilient disk whereby displacement of said facing disk upon the withdrawal of said platen therefrom is prevented, feeding means for said strip, and means subjecting said facing disk to a continuing pressure after it has been applied to said resilient disk.

9. A machine for making bottle caps embodying therein means adapted to apply a damping medium to a resilient disk for a bottle cap, means for applying previously gummed facing material to the portion of the disk to which said damping medium is applied and means whereby air under pressure is applied to said facing disk as said last named means recedes therefrom.

10. A machine for making bottle caps embodying therein means adapted to apply a damping medium to a resilient disk for a bottle cap, means for cutting a disk of facing material from a previously gummed strip and applying said disk to the dampened portion of said resilient disk, means whereby a continuing suction is applied to said facing disk after it is cut from said strip and until it is applied to the resilient disk, and feeding means for said strip.

11. A machine for making bottle caps embodying therein means adapted to apply a damping medium to a resilient disk for a bottle cap, means for cutting a disk of facing material from a previously gummed

strip, and applying said disk to the dampened portion of said resilient disk, an air pump co-operating with said last named means whereby the facing disk will be held by suction in a fixed relation to said means until it has been applied to said resilient disk and air under pressure will be applied to said facing disk as said last named means recedes, and feeding means for said strip.

12. A machine for making bottle caps embodying therein a reciprocatory damping mechanism adapted to apply a damping medium to the surface of the resilient disk for a bottle cap, a reciprocatory presser mechanism, means whereby previously gummed facing material is fed in relation to said presser mechanism, and means whereby the resilient disk is brought successively into the operative relation to said damping and said presser mechanisms.

13. A machine for making bottle caps embodying therein a reciprocatory damping mechanism adapted to apply a damping medium to the surface of a resilient disk for a bottle cap, a reciprocatory presser mechanism, means whereby facing material is fed in relation to said presser mechanism, and means whereby the resilient disk is brought successively into the operative relation to said damping and said presser mechanisms, and means whereby said facing material is subjected to a continuing pressure after leaving said presser mechanism.

14. A machine for making bottle caps embodying therein a reciprocatory damping mechanism, a reciprocatory presser mechanism, intermittently operative means simultaneously actuating said damping and said presser mechanisms whereby said damping mechanism will apply a damping medium to the surface of a resilient disk for a bottle cap and said presser mechanism will simultaneously apply previously gummed facing material to a previously dampened resilient disk, means whereby facing material is fed in relation to said presser mechanism and intermittently operative means whereby a sequence of resilient disks are successively brought into operative relation to said damping and said presser mechanisms.

15. A machine for making bottle caps embodying therein a reciprocatory damping mechanism, a reciprocatory presser mechanism, intermittently operative means simultaneously actuating said damping and said presser mechanisms, whereby said damping mechanism will apply a damping medium to the surface of a resilient disk for a bottle cap and said presser mechanism will simultaneously apply facing material to a previously dampened resilient disk, means whereby facing material is fed in relation to said presser mechanism, intermittently operative means whereby a sequence of resilient disks are successively brought into operative relation to said damping and said presser mechanisms and means whereby said resilient disks and the facing material thereon are subjected to a continuing pressure after they leave said presser mechanism.

16. A machine for making bottle caps embodying therein a reciprocatory damping mechanism embodying therein a yieldable nozzle adapted to apply a damping medium to the surface of a resilient disk for a bottle cap, means having a normal tendency to thrust said nozzle toward the resilient disk whereby said nozzle remains in engagement with said resilient disk for a sufficient period to ensure uniform application of the damping medium thereto, a reciprocatory presser mechanism, means whereby facing material is fed in relation to said presser mechanism, and means whereby said facing material is subjected to a continuing pressure after leaving said presser mechanism.

17. A machine for making bottle caps embodying therein a reciprocatory damping mechanism embodying therein a yieldable nozzle, an absorbent pad carried by said nozzle, a container for the damping medium, co-operating means carried by said container and said nozzle whereby the damping fluid will be forced into said pad upon the engagement of the pad with a resilient disk, and means having a normal tendency to thrust said nozzle toward said resilient disk whereby said pad remains in engagement with the resilient disk for a sufficient period to ensure uniform application of a damping medium thereto and the flow of the damping medium toward the end of the interval during which said pad is in engagement with said resilient disk will be checked, a reciprocatory presser mechanism, means whereby facing material is fed in relation to said presser mechanism, and means whereby the resilient disk is brought successively into the operative relation to said damping and said presser mechanisms.

18. A machine for making bottle caps embodying therein a reciprocatory damping mechanism embodying therein a container for the damping medium having a sub-chamber into which said medium flows, from said container through a constricted opening, a nozzle having a cup-like head in said sub-chamber, an absorbent pad carried by the lower end of said nozzle and a spring having a normal tendency to thrust said nozzle away from said container whereby said pad remains in engagement with a resilient disk for a sufficient period to ensure uniform application of a damping medium thereto and the flow of the damping medium toward the end of the interval during which said pad is in engagement with said resilient disk will be checked, a reciprocatory presser mechanism, means whereby facing material

is fed in relation to said presser mechanism, and means whereby the resilient disk is brought successively into the operative relation to said damping and said presser mechanisms.

19. A machine for making bottle caps embodying therein a reciprocatory damping mechanism for applying a damping medium to the central portion of one side of a resilient disk for a bottle cap, means for applying a previously gummed facing disk of substantially the same area as the dampened portion of said resilient disk thereto embodying therein a reciprocatory presser bar having a plurality of prongs about the edge thereof adapted to force the edge of said facing disk into said resilient disk, means whereby said facing disk is delivered into the operative relation to said presser bar and means whereby the resilient disk is brought successively into the operative relation to said damping and said presser mechanisms.

20. A machine for making bottle caps embodying therein a reciprocatory damping mechanism for applying a damping medium to the central portion of one side of a resilient disk for a bottle cap, means for applying a previously gummed facing disk of substantially the same area as the dampened portion of said resilient disk thereto, embodying therein a reciprocatory presser bar having a plurality of prongs about the edge thereof adapted to force the edge of said facing disk into said resilient disk, a platen and means whereby said prongs may be disengaged from said disks while said platen remains in engagement therewith, means whereby said facing disks are delivered into the operative relation to said presser bar and means whereby the resilient disk is brought successively into the operative relation to said damping and said presser mechanisms.

21. A machine for making bottle caps embodying therein a reciprocatory damping mechanism adapted to apply a damping medium to the surface of a resilient disk for a bottle cap, a reciprocatory presser mechanism, means whereby previously gummed facing material is fed in relation to said presser mechanism, means whereby said presser mechanism is held in engagement with said facing material after its application to the resilient disk for an interval to ensure the moistening of the gum on, and the adhesion of, said material to said resilient disk, and means whereby the resilient disk is brought successively into the operative relation to said damping and said presser mechanisms.

22. A machine for making bottle caps embodying therein a reciprocatory damping mechanism for applying a damping medium to the central portion of one side of a resilient disk for a bottle cap, means for applying a previously gummed facing disk of substantially the same area as the dampened portion of said resilient disk thereto, embodying therein a reciprocatory presser bar having a plurality of prongs about the edge thereof adapted to force the edge of said facing disk into said resilient disk, a platen slidably mounted therein adjacent said prongs a spring having a normal tendency to thrust said platen axially of said bar beyond said prongs and a stop limiting the outward movement of said platen, whereby said platen will force said facing disk into engagement with said resilient disk and subject it to a continuing pressure while said prongs force edge portions of the facing disk into the resilient disk and are withdrawn therefrom, means whereby a facing disk is delivered into the operative relation to said presser bar and means whereby the resilient disk is brought successively into the operative relation to said damping and said presser mechanisms.

23. A machine for making bottle caps embodying therein a reciprocatory damping mechanism for applying a damping medium to the central portion of one side of a resilient disk for a bottle cap, means for applying a previously gummed facing disk of substantially the same area as the dampened portion of said resilient disk thereto, embodying therein a reciprocatory presser bar having a plurality of prongs about the edge thereof adapted to force the edge of said facing disk into said resilient disk, a platen slidably mounted therein adjacent said prongs a spring having a normal tendency to thrust said platen axially of said bar beyond said prongs, a stop limiting the outward movement of said platen, whereby said platen will force said facing disk into engagement with said resilient disk and subject it to a continuing pressure while said prongs force edge portions of the facing disk into the resilient disk and are withdrawn therefrom, and independently operative means whereby said platen may be set relatively to said prongs and the tension of said spring may be regulated, means whereby a facing disk is delivered into the operative relation to said presser bar and means whereby the resilient disk is brought successively into the operative relation to said damping and said presser mechanisms.

24. A machine for making bottle caps embodying therein a reciprocatory damping mechanism for applying a damping medium to the central portion of one side of a resilient disk for a bottle cap, a presser mechanism for applying a previously gummed facing disk of substantially the same area as the dampened portion of said resilient disk thereto embodying therein a reciprocatory presser bar having a plurality of prongs

about the edge thereof adapted to force the edge of said facing disk into said resilient disk, a platen slidably mounted therein adjacent said prongs, a spring having a normal tendency to thrust said platen axially of said bar beyond said prongs, a stop limiting the outward movement of said platen whereby said platen will force said facing disk into engagement with said resilient disk and subject it to a continuing pressure while said prongs force edge portions of the facing disk into the resilient disk and are withdrawn therefrom, and means for holding the facing disk against said platen and facilitating the withdrawal of said platen from said facing disk after its application to the resilient disk comprising a cylinder carried by and movable with said presser bar, and a fixed piston co-operating therewith, said presser bar and said platen being provided with a duct opening into said cylinder and outwardly of said platen, means whereby a facing disk is delivered into the operative relation to said presser bar and means whereby the resilient disk is brought successively into the operative relation to said damping mechanism and said presser mechanism.

25. A machine for making bottle caps embodying therein means adapted to apply a damping medium to a resilient disk for a bottle cap, a presser mechanism for applying a previously gummed facing disc thereto and means whereby said resilient disk is centered relatively to said presser mechanism.

26. A machine for making bottle caps embodying therein a reciprocatory damping mechanism for applying a damping medium to the central portion of one side of a resilient disk for a bottle cap, means for applying a previously gummed facing disk of substantially the same area as the dampened portion of said resilient disk thereto embodying therein a reciprocatory presser bar having a plurality of prongs about the edge thereof adapted to force the edge of said facing disk into said resilient disk, means whereby a facing disk is delivered into operative relation to said presser bar, means whereby the resilient disk is brought successively into the operative relation to said damping and said presser mechanisms and means whereby said resilient disk is centered relatively to said presser mechanism.

27. A machine for making bottle caps embodying therein a reciprocatory damping mechanism for applying a damping medium to the central portion of one side of a resilient disk for a bottle cap, means for applying a previously gummed facing disk of substantially the same area as the dampened portion of said resilient disk thereto, embodying therein a reciprocatory presser bar having a plurality of prongs about the edge thereof adapted to force the edge of said facing disk into said resilient disk, means whereby facing disk is delivered into the operative relation to said presser bar, means whereby said resilient disk is centered relatively to said presser mechanism comprising a reciprocatory wedge encircling said presser bar, springs normally raising said wedge and means carried by said presser bar whereby said wedge will be forced into engagement with the metal portion of a bottle cap having a resilient disk therein prior to the engagement of the facing disk with said resilient disk and means whereby bottle caps having resilient disks therein are brought successively into the operative relation to said presser mechanism and a centering wedge.

28. A machine for making bottle caps embodying therein a reciprocatory damping mechanism for applying a damping medium to the central portion of one side of a resilient disk for a bottle cap, means for applying a previously gummed facing disk of substantially the same area as the dampened portion of said resilient disk thereto embodying therein a reciprocatory presser bar having a plurality of prongs about the edge thereof adapted to force the edge of said facing disk into said resilient disk, means whereby a facing disk is delivered into the operative relation to said presser bar, and means whereby said facing material is subjected to a continuing pressure after leaving said presser mechanism.

29. A machine for making bottle caps embodying therein a reciprocatory damping mechanism adapted to apply a damping medium to the surface of a resilient disk for a bottle cap, a reciprocatory presser mechanism, means whereby previously gummed facing material is fed in relation to said presser mechanism, means whereby said presser mechanism is held in engagement with said facing material after its application to the resilient disk for an interval to ensure the moistening of the gum on, and the adhesion of, said material to said resilient disk, and means whereby said facing material is subjected to a continuing pressure after leaving said presser mechanism.

30. A machine for making bottle caps embodying therein a reciprocatory damping mechanism for applying a damping medium to the central portion of one side of a resilient disk for a bottle cap, means for applying a previously gummed facing disk of substantially the same area as the dampened portion of said resilient disk thereto embodying therein a reciprocatory presser bar having a plurality of prongs about the edge thereof adapted to force the edge of said facing disk into said resilient disk, means whereby a facing disk is delivered into the operative relation to said presser bar, means whereby said resilient disk is centered rel-

atively to said presser mechanism comprising a reciprocatory wedge encircling said presser bar, springs normally raising said wedge, means carried by said presser bar whereby said wedge will be forced into engagement with the metal portion of a bottle cap having a resilient disk therein prior to the engagement of the facing disk with said resilient disk, means whereby bottle caps having the resilient disks therein are brought successively into the operative relation to said presser mechanism and a centering wedge, a support for the bottle cap axially below said presser bar and means adjacent said wedge adapted to engage the rim of said cap whereby movement of said cap is prevented while said facing disk is being delivered thereto.

31. A machine for making bottle caps embodying therein a reciprocatory damping mechanism for applying a damping medium to the central portion of one side of a resilient disk for a bottle cap, a reciprocatory presser bar having a plurality of prongs about the edge thereof, a platen slidably mounted in relation to said bar adjacent said prongs, a spring having a normal tendency to thrust said platen axially of said bar beyond said prongs, a stop limiting the outward movement of said platen, a die part having an opening therein adapted to cooperate with the edge of said platen and said prongs in cutting a disk of substantially the same area as the dampened portion of said resilient disk from a previously gummed strip whereby a facing disk will be forced by said platen into engagement with said resilient disk and be subjected to a continuing pressure while said prongs force edge portions of said facing disk into the resilient disk and are withdrawn therefrom, means feeding said strip relatively to said die part and said bar, and means whereby the resilient disk is brought successively into the operative relation to said damping mechanism below said die part.

32. A machine for making bottle caps embodying therein a reciprocatory damping mechanism for applying a damping medium to the central portion of one side of a resilient disk for a bottle cap, a reciprocatory presser bar having a plurality of prongs about the edge thereof, a platen slidably mounted in relation to said bar adjacent said prongs, a spring having a normal tendency to thrust said platen axially of said bar beyond said prongs, a stop limiting the outward movement of said platen, a die part having an opening therein adapted to cooperate with the edge of said platen and said prongs in cutting a disk of substantially the same area as the dampened portion of said resilient disk from a previously gummed strip whereby a facing disk will be forced by said platen into engagement with said resilient disk and be subjected to a continuing pressure while said prongs force edge portions of said facing disk into the resilient disk and are withdrawn therefrom, means feeding said strip relatively to said die part and said bar, means whereby the resilient disk is brought successively into the operative relation to said damping mechanism below said die part, means whereby the feeding of said strip will be prevented in the event of the failure of said last named means to bring a resilient disk into the operative relation to said die part and said bar.

In witness whereof, I hereunto affix my signature in the presence of two subscribing witnesses, this 13th day of April, 1916.

CHARLES E. McMANUS.

UNITED STATES PATENT OFFICE.

LEONARD BARTLETT, OF PHILADELPHIA, PENNSYLVANIA, ASSIGNOR TO AMERICAN CORK AND SEAL COMPANY, OF PHILADELPHIA, PENNSYLVANIA, A CORPORATION OF MAINE.

BOTTLE-SEAL-ASSEMBLING MACHINE.

993,288. Specification of Letters Patent. Patented May 23, 1911.

Application filed April 15, 1908. Serial No. 426,965.

To all whom it may concern:

Be it known that I, LEONARD BARTLETT, a citizen of the United States, residing at Philadelphia, in the county of Philadelphia and State of Pennsylvania, have invented a new and useful Bottle-Seal-Assembling Machine, of which the following is a specification.

This invention relates to machines for assembling bottle seals in which rubber gaskets and aluminum protecting disks are used; and has for its object to provide a machine of the character described in which the metal sealing caps may be placed, and the rubber gaskets and aluminum protecting disks are automatically placed in position within the cap; a further object being to provide a suitable gasket cutting machine which will operate in conjunction with the driving mechanism of the assembling machine, and which will cut the rubber gaskets and deposit them within the metal cap; a further object being to provide suitable mechanism to cut out and form the aluminum disks, and to force the disk when formed into the cap after suitable pasting apparatus has deposited sufficient paste to secure the disk to the metal cap, whereby the aluminum disk is brought into close contact with the center of the metal cap and may be secured thereto by the paste.

It is also the object of this invention to provide simple and coördinate parts which will work together to make an effective assembling machine.

The invention is illustrated in the accompanying drawings in which—

Figure 1, is a side elevation of a bottle seal assembling machine constructed according to my invention; Fig. 2, is a view of the opposite side of the machine, with the cap hopper and feed mechanism removed; Fig. 3, is a top plan view of the machine; Fig. 4, is a vertical section of the gasket cutting machine; Fig. 5, is a sectional view thereof on the line 5—5 of Fig. 4; Fig. 6, is a sectional view on the line 6—6, of Fig. 4; Fig. 7, is a perspective view of one of the cutting blades shown in Figs. 4, and 5; Fig. 8, is a face view of a part of the operating device for the gasket cutting machine; Fig. 9, is a side view of the same; Fig. 10, is a vertical section of the aluminum disk forming and depositing apparatus; Fig. 11, is a plan view of the forming and punching die; Fig. 12, is a side elevation of the operating mechanism for the aluminum feed; and, Fig. 13, is a side view of the main shaft and cams; and Fig. 14, is a sectional view of the seal assembled, on a larger scale.

In the drawings, like numerals of reference refer to the same parts in each of the views; and in practice I provide a frame 15, having a table, or platform 16, on which are mounted the assembling parts hereinafter described; and in the frame adjacent to the base thereof is mounted a shaft 17, which may be driven by a belt pulley as 18, by which the entire assembling machine may be operated.

The machine is adapted to assemble a seal, such as shown in Fig. 14, comprising a metal sealing cap, as 19, a rubber ring-shaped gasket 20, and an aluminum protecting disk 21, with a depressed center 22, adapted to contact with the center of the cap 19, within the gasket 20, and to be secured to said cap by adhesive material, or in any desired manner. To assemble these seals quickly, and in an economical manner, a hopper 23, is provided in which the metal caps may be placed, and in which apparatus of well known construction is operated to feed the caps down the chute 24, to a rotatable feed wheel 25′, within the channel 25, which carries the caps around to the wheel 26, having spaced notches, as 27, in the periphery thereof into which the caps are fed, and by this wheel 26, are fed to the different parts of the assembling machine in regular and definite order.

To operate the parts just described, a shaft 28, is pivotally connected with the rocking bar 29, the opposite end of which is connected with the shaft 30, which is operated vertically by the cam 31, on the shaft 17. This mechanism operates the hopper feed mechanism in a manner well known, and consequently, not more fully illustrated here. The feed wheel 25′, is rotated by the spur gear 32, on the shaft 17, which engages the spur gear 33, bracketed on the frame at 34, and which operates the beveled gears 35, and 36, and the shaft 37, connected with this wheel,—this part also being a well known construction. The notched wheel 26, is operated by mean of a worm 38, on the shaft 17, which engages successively pins 39, on

the wheel 40, mounted on the shaft 41, on the top of which the wheel 26, is mounted, whereby the wheel 26, is rotated forward in regular steps to carry the caps to the several assembling parts, and leave them in position a sufficient length of time for the parts to operate upon.

It will be understood that the metal caps are formed in separate machines, or punches; and are placed in this machine solely for the purpose of having the gaskets and protecting disks placed therein. Consequently, the parts described thus far have to simply feed these caps to the wheel 26, so as to place a cap in each notch 27, with the proper side up to receive the gasket and disk.

It is one object of this invention to form the metal disk and cut it out, and also form or cut the rubber gasket as well as assemble these parts in the cap to form the seal. As the gasket is deposited first, I will describe this part at this point, and the other parts of the machine in the regular order in which they operate.

It will be understood that the several parts, or assembling devices, are spaced a suitable distance apart, so that when the wheel 26, is held stationary by the pin 42, engaging successively the holes 43, in this wheel, in a manner well known in such machines, one of the notches will be directly beneath each device, and will remain there a sufficient length of time for each device to operate.

Referring to the gasket forming machine, or device,—this part is specially shown in a partial view at the right of Fig. 2, and specifically in Figs. 4, 5, 6, and 7; and the operating means specifically in Figs. 8 and 9. The gasket machine comprises a tube 44, of a size to receive a tubular section of rubber 45, as shown in Figs. 5, and 6; and the upper end of the tube 44, is secured in the arm 46, of the standard 47, and a second arm 48, supports the tube 44 centrally thereof, as particularly shown in Fig. 4. Slidably mounted on the tube 44, is an annular block 49, which is pivotally connected with a lever 50, which is pivoted at 51, to a cross plate 52, as specially shown in Fig. 8. The lever 50, is connected with the block 49, by the link 53, and yoke 54, which is pivoted at 55, to an arm 56, projecting from the arm 46. The lever 50, is provided with a depending arm 57, on the lower end of which is a friction roller 58, which is mounted between two guides 59, on a vertically movable block 60; and the upper ends of the guides are concentrically curved, as shown at 61, whereby when the block 60, descends until the roller 58, engages the curved parts of the guides, the roller will be carried laterally, as will be understood, and with it the lower end of the arm 57, of the lever 50, as will also be understood, causing the outer end of the lever 50, to descend; and as this is connected with the block 49, through link 53, and yoke 54, the block 49, will forced downward on the tube 44. The s block 60, is connected with a shaft 62, cured to a strap 63, on a cam 64, on shaft 17, by which this block is moved in guide frame 65. An annular ring 66, is slidably mounted on the tube 44, and is p vided with lugs 67, in which are pivota mounted the feed pawls 68, preferably t in number, and substantially triangu shape, as shown at the right in Fig. 4, w the vertical side provided with teeth, as in order to take a firm hold on the rubb tube. Pivotally mounted in the third corn of each pawl is a link 70, the upper end o which is pivotally connected with the annular block 49, and these links, three in number as shown, form the only connection between the block 49, and the ring 66, so that in lifting the annular block 49, the ring will be raised a short distance through the links 70, and pawls 68; but these links being connected with the outer corners of the triangular-shaped pawls, the pawls will be drawn backward out of the slots 71, in the tube 44. When, however, the annular block 49, is driven downward, as previously described, the links will drive the pawls inward until in tight contact with the rubber tube, and the rubber tube will be carried downward a short distance with the pawls and ring 66, as will be understood, to feed the rubber tube the required amount to form a gasket. Mounted on the lower end of the tube 44, is a sleeve 72, on which is rotatably mounted a belt wheel 73, secured to a ring 74, to which is clamped a grooved ring 75, in the grooves of which are mounted blades 76, preferably three in number, and of the form shown specially in Fig. 7, each blade having a hooked end 77, in which is mounted a spring 78, whereby the ends of the blades are held normally against the cam ring 79, which is non-rotatable. This cam ring is secured to a head 80, by posts 81, and is vertically movable therewith. The head 80, is loosely mounted on the tube 44, and is operated vertically by a crank lever 82, pivoted to the frame at 83, and carrying a friction roller 84, which engages the cam 85, on the shaft 17, the head 80, being sufficiently loose to allow of operation by the lever 82.

In operation the pulley 73, is operated by a belt 86, which engages a pulley 87, on the shaft 37. When a cap is directly beneath the tube 44, and the rubber has been driven down the required length to form a gasket, the cam 85 operates to force the head 80, downward, and with it the cam ring 79, the cam surface of which bears against the hooked end of the blades 76; and as this ring descends, the blades are driven inward into the rubber tube 45; and as the blades

are in the rotatable part, they are carried around rapidly as they are forced inward, thereby cutting off a section of the rubber tube to form a gasket; and, as previously mentioned, the cap being directly beneath, the tube 44, the gasket when cut will drop into the cap, and will be carried forward by the next movement of the wheel 26, and another cap will be brought under the tube for the repetition of the operation. To insure the positive operation of the knives, I prefer to provide a belt tension device, as 86'. After the gasket is deposited in the cap, the cap and gasket are carried forward to the paste machine 87ª, where a suitable amount of paste, or adhesive material is deposited in any desired manner so as to engage the center of the cap within the gasket ring; and the cap and gasket are then carried forward to the aluminum disk former and die. This part comprises a frame 87', carrying the sliding head 88, in which is mounted the forming tool 89, comprising a spring-controlled contact block 90, and a plunger 91, which forces the aluminum into the cavity 92, to form the projecting portion 22, which afterward engages the center of the cap, as previously described. After the projection 22, is formed, the aluminum strip 94, is fed forward by the feed rolls 95, which are operated by the pawl mechanism shown in Fig. 12, operated by a plunger shaft 96, connected with a lever 97, operated by a cam 98, the pawl mechanism in Fig. 1, being indicated by 99. By this arrangement the aluminum is fed forward step by step as needed, and the required distance so that at the next movement the projecting portion 22, will be directly beneath the punch 100, and centrally thereof, so that the circular plate 101, of the punch will enter this projection, and after the disk is punched out and carried down through the die 102, the plate 101, will force the portion 22, into close contact with the center of the cap within the gasket ring, and the cement, or adhesive material will secure this portion to the cap whereby the rubber gasket will be permanently secured in position. After the seal is assembled, as described, it is carried forward to the chute 103, and a plunger 104, secured to the punch head, will insure the dislodgment of the completed seal, as will be understood. The punch is operated by a shaft 105, and cam 106, on the shaft 17.

As the operation of the several parts has been fully described in connection with each part, it will not be necessary to again describe the operation of the complete machine further than to state that as all of the parts are operated by the main driving shaft 17, on which the respective cams are mounted, and adjusted to bring into action the several parts at the proper time to insure the perfect working of the machine, all the parts will work together harmoniously and automatically to insure the production of perfect seals.

Having thus described my invention, what I claim as new and desire to secure by Letters Patent of the United States, is—

1. A bottle seal assembling machine comprising a cap feeding device, a gasket cutting device, and a disk forming device, and means to feed the caps from said feeding device to the gasket cutting device and disk forming device consecutively, for the purpose set forth.

2. A bottle seal assembling machine comprising a cap feeding device, a gasket cutting device, and a disk forming and placing device, means to feed a cap successively from said feeding device to the other devices named, and means to operate said parts in unison, for the purpose set forth.

3. A bottle seal assembling machine comprising a cap feeding device, a gasket cutting and placing device, a paste depositing device, and a disk depositing device, means to feed a cap successively from said feeding device to the other devices named, and means to operate said parts in unison, for the purpose set forth.

4. A bottle seal assembling machine comprising a cap feeding device, a gasket cutting and placing device, a paste depositing device, and a disk placing device, means to feed a cap successively from said feeding device to the other devices named, and means to operate said devices harmoniously, for the purpose set forth.

5. A bottle seal assembling machine comprising a cap feeding device, a gasket cutting and placing device, a paste depositing device, and a disk forming and placing device, means to feed a cap successively from said feeding device to the other devices named, and means to operate said devices in harmony, for the purpose set forth.

6. A bottle seal assembling machine comprising a cap feeding device, a gasket placing device, and a disk forming and placing device, means to feed a cap from said feeding device to the other devices successively, and means to operate all of said devices in unison, for the purpose set forth.

7. A bottle seal assembling machine comprising a cap feeding device, a gasket cutting and placing device, a paste depositing device, and a disk forming and placing device, and a driving shaft carrying cams and a gear, said cams being so mounted as to operate said parts in harmony, as and for the purpose set forth.

8. In a bottle seal assembling machine, a gasket cutting device comprising a material holder, a feeding device, a rotatable part, and means to rotate the same, spring-controlled blades mounted to move in a radial direction in said rotatable part, means to

force said blades into the gasket material periodically, and means to operate said feeding device alternately with said blade-forcing-means, for the purpose set forth.

9. In a bottle seal assembling machine, a gasket cutting device comprising a material holding tube, a slide block mounted thereon, a slide ring mounted on said tube beneath said block, triangular-shaped pawls pivoted to said ring, and having teeth adapted to pass within slots in said holding tube to engage the gasket material, links connecting the outer corner of said pawls and said block, means to raise and lower said block whereby said ring is raised and lowered and said pawls are operated to feed said material, a rotatable member at the bottom of said tube and means to rotate the same, blades in said rotatable member, and a cam ring adapted to force said blades into the gasket material, and a main shaft on said machine adapted to operate said block and said cam ring alternately, as and for the purpose set forth.

10. In a bottle seal assembling machine, a disk forming and placing device comprising a pressure block and forming tool and die, and a cutting out die and placing tool carried by the same head, means to feed the metal from said forming tool and die to said cutting out die whereby the metal that is acted on by the forming die at one stroke is operated on by the cutting out die at the next stroke and a disk with a cup-shaped center and laterally-extending flange is formed and placed in position, and means to operate said device in harmony with the other parts of the assembling machine, for the purpose set forth.

11. In a bottle seal assembling machine, a disk forming tool and die and a combined cutting out die and placing tool carried by the same head, means to feed the metal from said forming tool and die to said cutting out die whereby the metal that is acted on by the forming die at one stroke is operated on by the cutting out die at the next stroke with the disk unchanged in shape by the cutting out die, said cutting out die and placing tool being spring controlled, for the purpose set forth.

12. In a device of the class described, the combination of mechanism for automatically cutting a strip of sealing substance into sections, mechanism for automatically positioning such sections within metallic caps, mechanism for automatically bringing said caps into position for receiving said sealing substance, mechanism for automatically forming a retaining member for said section, and mechanism for automatically placing and securing said retaining member in place within the cap, all of the mechanism being driven from a common power shaft, substantially as described.

13. In a device of the class described, the combination of mechanism for feeding a strip of sealing substance into position to be cut into sections, means for automatically performing said cutting operation, a rotatable ring having a series of recesses therein adapted to carry metallic caps, means for automatically rotating said ring in a step by step movement, means for positioning the severed section of sealing substance within said cap, a reel carrying a roll of sheet metal, means for feeding said sheet of metal into position to have retaining members formed from the sealing substance formed and cut therefrom by forming and cutting dies, means for positioning and securing said retaining members within the cap, and means for depositing a drop of adhesive substance within the cap prior to the insertion of the retaining member, substantially as described.

14. In a bottle seal assembling machine, a gasket placing device, and a disk forming and placing device, means to feed a cap from said gasket placing device to said disk forming and placing device, and means to operate both of said devices in unison.

Dated this 8th day of April, 1909.

UNITED STATES PATENT OFFICE.

MELCHOR MARSA, OF NEW YORK, N. Y., ASSIGNOR, BY MESNE ASSIGNMENTS, TO NEW PROCESS CORK COMPANY, INC., OF NEW YORK, N. Y., A CORPORATION OF NEW YORK.

METHOD OF MANUFACTURING BOTTLE CLOSURES.

Application filed May 15, 1925. Serial No. 30,531.

The present invention relates to the manufacture of bottle closures of the cap variety, including those commonly known as "crown corks".

Closures of this type usually comprise a metallic cap, having a corrugated flange to be locked to the exterior of the bottle neck, and a sealing disk or packing of cork or the like within and cemented to the cap and adapted to be seated against the top of the neck of a bottle, to make a gas- and liquid-tight joint.

Various kinds of cementing materials have been employed heretofore in producing these closures, and the method of making the closure depends mainly on the character of the cementing material employed. In some cases, for instance, fusible cements or binding materials are used; in others cements are employed which are coagulated by heat. As far as known, in all closures heretofore manufactured the cementing material is inserted into the metallic cap after the same has been shaped or formed, preferably by stamping operation, and the sealing or packing disk deposited into the cap on top of the cementing material, the assembled closure being then subjected to further operations, so as to unite the disk with the cap by the aid of the cement.

The main object of the present invention is to reduce the number of steps heretofore employed in assembling and uniting the elements of the closures, and thereby not only simplifying the machines by which the closures are assembled and united, but also reducing the period of manufacture due to the number of reduced steps of the method employed.

With these and other objects in view, which will more fully appear as the nature of the invention is better understood, the method herein described consists, generally speaking, in applying a cementing material to the metal sheet from which the caps are cut and formed into caps, more particularly to those portions of the sheet which are to constitute the inner faces of the heads of the caps; forming the caps; inserting thereinto the packing disks; and then uniting the caps and disks by the aid of the cementing material.

The several steps of one of the many possible methods are illustrated in the accompanying drawings, in which:

Figure 1 illustrates the surface of a piece of sheet metal of which the caps are to be formed, having the cementing medium applied thereto in circular spots; Fig. 2 is a central vertical section taken through the assembled closure, the same being heated by a source of heat, such as a gas flame; and Fig. 3 is a similar section taken through the closure, the elements thereof being held under pressure while being cooled.

Referring now to the drawings, the numeral 10 indicates a piece of sheet metal, to one face of which is applied in circular spots 11 a cementing medium. This cementing medium is, preferably, a resinous substance in solution, it being odorless and tasteless in order to meet the requirements, and it being applied to the sheet in any suitable manner while in solution. The circular spots 11 are of a size corresponding substantially to that of the inner faces of the heads 12 of the caps to be formed, and are properly spaced corresponding to the spacing of the dies of the press on which the sheet is initially cut along the dotted lines 13 in the process of shaping and forming the caps.

After the cementing material has been applied to the metal sheet, the latter is subjected to high temperature, preferably, in an oven, to evaporate the solvent of the cementing material. The sheet may thus be handled without danger of removing the cementing material therefrom.

The sheet is then placed into a press and the caps shaped and formed, one of the same being indicated by the numeral 14 (Figs. 2 and 3). This cap comprises a head 12, as above stated, and a corrugated flange 15, the latter being applied to and locked to the exterior of the bottle neck to be closed. On top of the cementing material is placed within the cap a packing disk 16 of cork or the like, and thereafter heat is applied to the assembled elements of the closure. Any suitable source of heat may be used, for instance a gas burner 17, from which issues a jet 18, preferably striking the outer face of the head of the cap. The cementing material is thus fused. The assembled closure is thereupon placed on a support 19, and the

elements thereof placed under compression, for instance by a plunger 20 bearing against the exposed face of the packing disk 16, and the closure cooled in any suitable manner, to harden the cementing material, whereby the elements of the closure are firmly united.

This type of bottle closures is usually produced on automatic machines, all of which must, of necessity, contain a mechanism for depositing into the metal caps of the closures a cementing material, either in liquid or viscous form, or in the form of paper collet, treated with the cementing medium. It is obvious that the machines for carrying out the method herein described do not need the cement feeding and depositing means, and, therefore, they are not only simplified in construction but permit of a faster turning out of the closures. In the present method the cementing material is applied to the metal sheets, of which the closures are to be formed, simultaneously with the steps necessary for treating the same, preparatory to the cutting and shaping operations. These steps include shellacking of the sheets and decorating the same, that is to say printing thereon trade-marks or other information, which is to appear on the outer faces of the heads of the caps.

It is obvious that, while in the method herein described heat is applied to the assembled closures previous to the elements thereof being placed under compression, heat may be applied, to fuse the cementing material, before the packing disks are placed into the caps, or after the elements of the closure have been put under compression without departing from the invention, which lies mainly in applying the cementing medium to the sheet, of which the caps of the closures are to be shaped and formed. It is entirely immaterial, as far as the method, forming the subject matter of the present application for Letters Patent is concerned, at which stage of manufacture the said cementing medium is fused or softened.

It is also obvious that, instead of a fusible cementing medium, a cement may be employed which is coagulated by heat. In such case the closures, after the elements thereof have been assembled, are placed under compression and heated to coagulate the cement, whereby an almost instantaneous union is formed between the caps and the packing disks therein.

What I claim is:—

1. The method of manufacturing bottle closures of the cap variety which consists in, first, applying to one face of the metal sheet of which the caps of the closures are to be formed a fusible cementing material in spots, each spot being of a size corresponding substantially to the area of the inner face of the head only of a cap to be formed, second, cutting the sheet around the said spots and shaping the caps, so that the inner face of the head of each cap is substantially covered with cementing material, third, inserting into a cap a packing disk of cork or the like, fourth, fusing the cementing material, and, fifth placing the cap and the packing disk therein under pressure and cooling the assembled closure so as to harden the cementing material.

2. Those steps of manufacturing bottle closures of the cap variety which consist in, first, applying to one face of the metal sheet of which the caps of the closures are to be formed a cementing material in spots, each spot being of a size corresponding substantially to the area of the inner face of the head only of a cap to be formed, and, second, cutting the sheet around the said spot and shaping the caps, so that the inner face of the head of each cap is substantially covered with cementing material.

3. The method of manufacturing bottle closures of the cap variety which consists in applying to one face of the metal sheet of which the caps of the closures are to be formed a fusible cementing material in spots, each spot being of a size corresponding substantially to the area of the inner face of the head of a cap to be formed, cutting the sheet around the said spots and shaping the caps, so that the inner face of the head only of each cap is substantially covered with cementing material, inserting into a cap a packing disk of cork or the like, fusing the cementing material either before or after the insertion of the packing disk, and cooling the assembled closure under pressure so as to harden the cementing material.

4. The method of manufacturing bottle closures of the cap variety which consists in applying to one face of the metal sheet of which the caps of the closures are to be formed a cementing material in spots, each spot being of a size corresponding substantially to the area of the inner face of the head only of a cap to be formed, cutting the sheet around the said spots and shaping the caps, so that the inner face of the head of each cap is substantially covered with cementing material, inserting into a cap a packing disk of cork or the like, and thereafter subjecting the assembled closure to further treatment to unite the elements thereof.

Signed at New York, in the county of Kings and State of New York, this 8th day of May, A. D. 1925.

UNITED STATES PATENT OFFICE.

EMILIO ALBERTI AND JOHN ALBERTI, OF NEW YORK, N. Y., ASSIGNORS TO INTERNATIONAL CORK COMPANY, OF BROOKLYN, NEW YORK, A CORPORATION OF NEW YORK.

MACHINE FOR MANUFACTURING CLOSURES FOR BOTTLES AND OTHER RECEPTACLES.

1,401,300. Specification of Letters Patent. Patented Dec. 27, 1921.

Application filed June 19, 1916. Serial No. 104,550.

To all whom it may concern:

Be it known that we, EMILIO ALBERTI and JOHN ALBERTI, citizens of the United States, and residents of the city of New York, in the county of Kings and State of New York, have invented certain new and useful Improvements in Machines for Manufacturing Closures for Bottles and other Receptacles, of which the following is a specification.

The present invention relates to a machine for manufacturing closures or stoppers for bottles and other receptacles; more particularly it pertains to closures of the cap variety, including those termed "crown corks."

Closures of this type usually comprise a metallic cap or crown to be locked to the neck of the bottle, etc., and a sealing disk or packing of cork or the like, that is held within the cap, for instance by means of a suitable cementing medium. It has been found in practice that in many cases it is impracticable to permit the liquid contents of the bottle or other receptacle to come into contact with the sealing disk of cork or like material, as some liquids, such as pure water, mineral water, or beverages of delicate flavors, are apt to acquire "a corky taste." The commercial value of such liquids is thus greatly impaired. In order to obviate these and similar defects of the crown corks and like closures, it has been found convenient to cement or otherwise attach a thin protecting disk of ductile metal or other material to the exposed face of the sealing disk of the closure, which protecting disk should preferably be of a diameter that is substantially smaller than that of the sealing disk, but slightly larger than the inner diameter of the neck of the receptacle to which the closure is to be applied.

The main object of the present invention is to provide a simple and efficient machine for applying the protecting disks to the closures.

With this and other objects in view, which will more fully appear as the nature of the invention is better understood, the same consists in the combination, arrangement and construction of parts hereinafter fully described, pointed out in the appended claims and illustrated in the accompanying drawings, it being understood that many changes may be made in the size and proportion of the several parts and details of construction within the scope of the appended claims without departing from the spirit or sacrificing any of the advantages of the invention.

The machine constructed in accordance with this invention comprises, broadly speaking, an intermittently moving closure transporting mechanism, in combination with means for applying a cementing medium to the exposed face of the sealing disks, means for cutting from a strip of metal or other material protecting disks and placing the same into the closures, and heating means for the cementing medium.

One of the many possible embodiments of the invention is illustrated in the accompanying drawings, in which:—

Figure 1 is a side elevation of a machine constructed in accordance with this invention; Fig. 2 is a top plan view of the same; Fig. 3 is a section taken on line 3—3 of Fig. 1; Fig. 4 is a side elevation, partly in section, of the means for actuating the moving parts of the machine; Fig. 5 is a section taken on line 5—5 of Fig. 4; Fig. 6 is a side elevation of the mechanism which applies the cementing means to the exposed faces of the sealing disks of the closures; Fig. 7 is a top plan view thereof; Fig. 8 is a section taken on line 8—8 of Fig. 6; Fig. 9 is a development of a cam shown in Figs. 6 and 8; Fig. 10 is a side elevation of the means for feeding a strip from which the protecting disks are to be cut and the cutting and depositing means coöperating therewith; Fig. 11 is a section taken on line 11—11 of Fig. 10; Fig. 12 is a section taken on line 12—12 of Fig. 10; Fig. 13 is a rear elevation of the heating means of the apparatus; Fig. 14 is a central vertical section taken through a finished closure; and Fig. 15 is a bottom plan view of said closure.

Before describing the machine constructed in accordance with the present invention, the product manufactured thereon will be disclosed in connection with Figs. 14 and 15 of the drawings. In these figures a bottle closure of the crown cork type has been shown for purposes of illustration, it being, however, obvious that the machine may be used for manufacturing generally closures of the cap variety. In Figs. 14 and 15 the numeral 10 indicates a cap, comprising a

substantially cylindrical head 11 and a corrugated flange 12, which is adapted to be locked in the well known manner to the exterior of the bottle neck. In the cap is disposed a sealing disk or packing 13 of cork or like material, which is united with the cap, for instance, by an interposed cementing material 14, or in any other suitable manner. To the outer, or in other words to the exposed face of the sealing disk is attached concentrically with the latter a thin layer of material, such as, for instance chemically pure block tin, aluminum, an alloy of tin, or suitably prepared paper. This layer is made in the form of a disk, denoted by the numeral 15, its diameter being smaller than the diameter of the sealing disk and being stuck to the latter by an interposed cementing medium, shown at 16. This cementing medium should, preferably be of a type that is insoluble in liquids after it has set and formed a union between the packing and the protecting disk 15; it should be insoluble at normal temperatures and at temperatures above normal. It has been found in practice that albumen is particularly adapted for use in connection with these caps, it being inodorous, tasteless, soluble in water and thus readily preparable for use. Moreover albumen coagulates easily and is rendered insoluble at about 140° Fahrenheit, the coagulation resulting in a firm union between the packing of cork or the like and the protecting disk, such union being brought about almost instantaneously.

The machine for applying these protecting disks to the closures comprises a frame 17, including a horizontal table portion 18, above the plane of which is arranged a star wheel 19, having recesses or pockets 19′, into which are seated crown corks in their inverted positions. This star wheel is attached to a vertical shaft 20, which is suitably journaled in bearings 21 and 22 upon the frame and receives intermittent rotary motion, to rotate in a like manner the star wheel 19 in the direction of the arrow shown in Fig. 2 of the drawings. Any suitable means may be provided for this purpose, the one described herein being disclosed only for purposes of illustration. This means comprises a driving shaft 23, journaled in bearings upon the frame and driven in any suitable manner, for instance it may carry a fixed pulley 24 and a loose pulley 25, over which runs a belt (not shown in the drawings). To the driving shaft is keyed an eccentric 26, to the strap 27 of which is attached a rod 28, that is pivoted at 29 to a lever 30, the latter being fulcrumed at 31 to the frame of the machine. To the rod 28 is fixedly secured an upwardly projecting finger 32, that is adapted to coact with projections 33 upon the underface of a disk 34, the latter being rigidly attached, for instance by a screw 35, to the shaft 20. As the eccentric actuates the rod 28, the path described by the finger 32 thereon during each revolution of said eccentric will be an ellipse, as clearly shown in dotted lines in Fig. 4 of the drawings, the result being that said finger is brought into engagement with one of the projections 33 upon the disk 34 and causes the said disk to move in the direction of the arrow shown in Figs. 3 and 5 of the drawings a predetermined portion of a complete turn, after which the said finger is disengaged from the said projection to be brought into engagement with the next projection in the series, and so on. In order to maintain the disk 34 stationary while the finger 32 is disengaged from a projection and brought into engagement with the next in the series, there is a centering lug 36 provided. This lug is slidably disposed in a bracket 37, its lower free end carrying a roller 38, that is adapted to coöperate with a cam 39, the latter being keyed to the driving shaft. The lug coacts with a row of apertures 40 in the disk 34, the cam and the eccentric being keyed to the shaft in such relation that immediately before the finger 32 is disengaged from a projection 33 on the disk 34, the said centering lug is forced into one of the apertures 40 and held therein until the said finger is about to be brought into engagement with the next projection in the series, when a spring 41 coiled upon the centering lug, unseats the latter. There is provided an additional means for disengaging the centering lug 36 from the disk. This means comprises an extension 42 upon the centering lug in the path of a projection 43 upon the cam 39. This projection forces the extension 42 at the proper moment downward, thereby disengaging the center lug from an aperture 40. This additional means is provided in order to prevent breakage of the moving parts of the machine in case the spring 41 should fail to act.

Above the star wheel 19 is mounted upon the table portion 18 a guide 44 for the purpose of holding the crown corks upon the said star wheel. The crown corks are fed in their inverted positions one after the other to the recesses 19′ of the star wheel by any suitable means, for instance the said crown corks may be placed into a hopper and brought by suitable feeding means in proper position into a chute 45, that leads to an aperture 46 in the guide 44. Through this aperture the crown corks are caused to move by means (not shown in the drawings) one after the other into the recesses 19′ in the star wheel. A device of this type is disclosed in application for U. S. Letters Patent, filed by Alexander Bogdanffy and John Alberti, on Oct. 16, 1913, under Serial #795,481. Obviously a crown cork is fed to a recess when the star wheel is at rest, the

latter being mounted in such a manner upon the shaft 20 that, whenever the star wheel is at rest, one of its recesses will be in alinement with the aperture 46 in the guide 44.

The crown corks are preferably assembled on a separate machine and brought into the hopper communicating with the chute 45, although the machine herein described may be combined with and form part of the assembling machine.

The star wheel conveys the crown corks step by step to a mechanism which applies adhesive material to the exposed faces of their sealing disks. The adhesive material is obviously applied to that area of a sealing disk which is to be covered by a protecting disk 15. The mechanism comprises a container 47, holding a cementing medium in liquid form of the type above described. This container is provided with a spout 48, through which the adhesive material flows drop by drop into a, preferably, cylindrical open receptacle 49, that is rotatably mounted upon a spindle 50, the latter being fixedly secured to the table portion 18. Upon this receptacle is formed a gear 51, in mesh with a gear 52, that is keyed or otherwise fixedly attached to a shaft 53, the latter being rotatably mounted in a bearing 54, and carrying upon its lower end a cam 55, that is shown in its developed form in Fig. 9 of the drawings. This cam comprises a cylindrical member, having a peripheral groove 56, said groove comprising three vertical portions 57, which are connected by curved portions 58. In the groove is seated a lug 59, formed upon a standard 60, that is attached to or made integral with a guide 61, into which extends shiftably a rod 62, the upper reduced end 63 of which projects into the cam 55, while its lower end carries a pin 64, that is seated in a slot 65 of a lever 66. This lever is fulcrumed at 67 to a bridge 68 upon the frame 17, and carries upon its free end an anti-friction roller 69, that is in engagement with a cam 70, the latter being keyed to the driving shaft 23. The reduced portion 63 of the rod 62 is connected with the shaft 53 to cause the latter to reciprocate with the rod 62, but allowing the said shaft to rotate upon the said rod. The cam 70 elevates the rod 62, and for lowering the latter there is loosely mounted upon the same a collar 71, against which bears one end of a spring 72, that is coiled upon the said rod, its other end bearing against a shoulder 73 thereon. As the rod 62 is elevated, its collar 71 will abut against the guide 61, whereby the spring 72 is compressed. After the rod has completed its upward stroke and the cam 70 allows it to descend, the spring 72 expands, thereby forcing the rod 62 and the parts connected therewith downward, keeping continuously the anti-friction roller 69 in contact with the cam 70. As the rod 62 is reciprocated, the lug 59 coöperating with the groove 56, causes the shaft 53 to be rotated step by step. When the shaft 53 is in its uppermost position (Fig. 6), the lug 59 is in one of the curved portions 58 of said groove, as shown in dotted lines in Fig. 9 of the drawings (position I). As now the rod 62 descends, the cam 55 is given a partial turn until the lug is brought into the position indicated by the numeral II in Fig. 9 of the drawings. During the further descent of the rod, the shaft 53 is held against rotary motion, owing to the fact that the lug 59 travels in one of the straight portions 57 of the groove. During the upward motion of the rod 62, for some time the shaft 53 is held against rotary motion, but will be given a partial turn when the lug 59 reaches again one of the curved portions 58 of the cam. The purpose of this arrangement will be explained hereinafter.

To the upper end of the shaft 53 is attached a star-like bracket 74, comprising in the case illustrated three arms, in each of which is shiftably mounted a spindle 75. The lower free end of each spindle carries a cylindrical block 76 of rubber or like material. A spring 77, wound upon each spindle, causes the same to descend, its downward movement being limited by a stop 78, which is adapted to abut against the upper face of the respective arm of the bracket 74. The upper face of the bottom of the receptacle 49 is disposed a considerable distance above the upper face of the star wheel, as clearly appears from Fig. 6 of the drawings. The three spindles 75 are located in relation to the star wheel and the receptacle 49 in such a manner that one of the same is, when the shaft 53 is held against rotation, in alinement with the said receptacle and another one is adapted to move through an aperture 79 in the guide 44 into contact with the exposed face of a crown cork on said star wheel. The diameter of the aperture 79 is somewhat larger than that of the head portion of a crown cork, as appears from Fig. 6 of the drawings.

The operation of the cementing material applying device is as follows: When the rod 62 is caused to move downward, one of the rubber blocks 76 contacts with the inner face of the receptacle 49 before another one of said blocks is brought into contact with the exposed area of the crown cork in alinement with the aperture 79 in the guide 44. It is to be noted that the star wheel moves while the rod 62 and the parts carried thereby move upward, and is caused to come to a stop when the said rod moves downward or at least during that period of the downward motion when one of the rubber blocks 76 is caused to contact with the exposed face of the sealing disk of a crown cork. The rubber block coming into con-

tact with the bottom of the receptacle 49 is coated upon its plane underface with adhesive material, and is then moved, upon the next partial turn of the shaft 53, into registering position with the aperture 79 when, in moving downward, it applies the adhesive to a portion of the exposed face of the sealing disk of the crown cork resting therebelow. The springs 77 and the spindles 75 permit a rubber block to contact with a sealing disk for some time, the stroke of the rod 62 being greater than the distance between the sealing disk and the lower face of a block 76, considering the highest position of a block. Inasmuch as the upper face of the bottom of the receptacle 49 is disposed a considerable distance above the star wheel, a rubber block will be in contact with the bottom of the receptacle 49 for a longer period of time than the block is in contact with a sealing disk. There will be ample time thus to coat the underface of a block with adhesive. Inasmuch as the receptacle 49 is rotated, the rubber blocks will contact always with other spots of the receptacle 49, and inasmuch as a rubber block, when in the receptacle, is dragged along the bottom thereof, a proper coating of a block therein will take place.

The crown corks to which adhesive has been applied are conveyed by the star wheel to the means which cuts the protecting disks from a strip and places the same into the crown corks. The strip of metal or other material, from which the protecting disks are to be cut, is wound upon a reel 80, which is suitably journaled in a bracket 81. From this reel the strip is conducted into a guide 82, to pass between feeding rollers 83 and 84. The feeding roller 83 is journaled in the table portion of the machine frame, while the roller 84 is journaled in bearings 85, which project above the table portion and are under the tension of springs 86, forcing the roller 84 toward the roller 83. To the spindle of the roller 84 is fixedly attached a gear 87, in mesh with a pinion 88, that is keyed to the spindle of the roller 83. The roller 84 is actuated by a pawl and ratchet-wheel mechanism. For this purpose a ratchet wheel 89 is fixedly attached to the spindle of the roller 84, in mesh with a pawl 90, that is pivoted at 91 to a frame 92, the latter being oscillatably mounted upon the spindle of the roller 84. To this frame is pivoted at 93 a connecting bar 94, the other end of which is pivoted at 95 to the lever 30 above described. The lever is actuated, as above described, by the eccentric 26. When this eccentric moves the connecting bar in the direction of the arrow indicated in Fig. 10, the frame 92 is shifted so as to bring the pawl 90, which is under the tension of a spring 96, into engagement with one of the teeth of the ratchet wheel, and as the said connecting bar moves in the opposite direction, the feeding rollers are caused to rotate and to advance the strip 97, from which the protecting disks are to be cut, to the cutting means of the machine. The cutting means comprises a tubular punch 98, secured in any suitable manner to a slide 99, that is adapted to reciprocate in a vertical guide 100, the latter being attached to the table portion of the machine frame. The slide is actuated from the driving shaft 23 in the following manner: Upon the said driving shaft is mounted an eccentric 101, its strap 102 having an eccentric rod 103, that is pivoted at 104 to the said slide. The eccentrics 101 and 26 are timed in such a manner that whenever the star wheel is in motion, the slide 99 is caused to move upward and, whenever the star wheel is at rest, the said slide moves downward, whereby the punch 98 cuts a protecting disk from the strip 97, which disk is automatically forced through an opening 105 in the guide 44 into a crown cork, that is held stationary in alinement with the said opening. The means for forcing the disk into the crown cork comprises a stem 106, part of which is disposed within the tubular punch 98, its upper end projecting above the said punch and being provided with a head 107. A spring 108, coiled upon the said stem, rests against the said head and the slide. With the head coöperates a lever 109, that is fulcrumed at 110 and 111 to the guide 100 and slide 99, respectively. This lever is disposed above the head of the stem 106. When, therefore, the slide moves downward and cuts a protecting disk, the lever 109 will be brought into contact with the head 107 after the cutting operation is performed, but before the downward stroke of the slide is completed. After engagement, the stem will be forced downward by the lever 109 and the protecting disk into the crown cork. Upon the upward stroke the spring 108 expands and returns the stem to the position shown in Fig. 10 of the drawings.

The protecting disk having been deposited in the crown cork, the latter is transported by the star wheel within the reach of heating means, which coagulates the cementing medium so as to form a firm union between the protecting and sealing disks, said heating means serving at the same time to flatten the protecting disk to prevent the formation of wrinkles which would materially decrease the value of the product obtained. For this purpose one or more plungers may be used, which may be heated in any suitable manner. In the case illustrated in the drawings there are three plungers made use of, denoted in their order by the numerals 112, 113 and 114. These plungers are carried by and fixedly attached to a bracket 115, that is secured to a recipro-

cable rod 116, mounted in guides 117. Upon the lower end of this rod is formed a pin 118, seated in a slot 119 of a lever 120, that is fulcrumed at 121 to the frame of the machine, and provided upon its free end with an anti-friction roller 122, coöperating with the cam 39 above described. A spring 123, coiled upon the rod 116 and bearing against a head 124 upon the lower portion thereof and against one of the guides 117, holds continuously the anti-friction roller 122 in contact with the cam 39 and causes a downward movement of the plungers. These plungers are heated in the case illustrated in the drawings electrically, the electric conductors being shown at 125, but the means which translate the electric energy into heat has not been shown, as the same is well known and does not form part of this invention. The rod 116 is caused to move on its upward stroke when the star wheel is moving, and to descend when the said star wheel is at rest, whereby the heated plungers move through apertures 126 in the guide 44 into contact with the protecting disks in three neighboring crown corks, the apertures 126 being obviously in alinement with recesses in the star wheel when the latter is at rest. Heat is thus transmitted by the protecting disks, which are in contact with the plungers, to the cementing medium, which is thereby coagulated, and forms a firm union between the protecting and sealing disks. The underface of the plunger 112, which is the first in order to contact with a sealing disk, is convex, so that it comes into contact with the central portion only of a protecting disk. The underface of the next plunger in the series, towit: plunger 113, is less convex so that it will contact with a larger area of a protecting disk, and the underface of the plunger 114 is flat, thus making contact throughout the area of a protecting disk. The purpose of this arrangement is to expel air between the protecting and sealing disks, which air would prevent a proper union between the same. Another purpose of this arrangement is to gradually and effectively flatten the protecting disks, or in other words to prevent the formation of wrinkles in the said disks, which greatly impair the commercial value of crown corks of this type.

After this operation, the crown corks are advanced to a chute 127, into which they are caused to move by an abutment 128 upon the machine frame. In this chute the crown corks slide into a collecting receptacle (not shown).

What we claim is:—

1. In a machine for applying protecting disks to closures of the cap variety, the combination with means for applying a cementing material to the exposed face of the sealing disk of the complete closure, means for placing a protecting disk on top of and in contact with the cementing material, and means for applying pressure to the closure for maintaining said contact.

2. In a machine for applying protecting disks to closures of the cap variety, the combination with means for applying a cementing material to the exposed face of the sealing disk of the complete closure, means for placing a protecting disk on top of and in contact with the cementing material, and means for applying pressure to the closure for maintaining said contact and flattening the protecting disk.

3. In a machine for applying protecting disks to closures of the cap variety, the combination with means for applying a cementing material to the exposed face of the sealing disk of the closure, means for placing a protecting disk on top of and in contact with the cementing material, and a plurality of plungers acting in succession for applying pressure to the closure for maintaining said contact, the acting underface of the last plunger in the series being plane and those of the others convex, whereby they flatten gradually the protecting disk.

4. In a machine for applying protecting disks to closures of the cap variety, the combination with means for applying to the exposed face of the sealing disk of the complete closure a suitable cementing medium adapted to be coagulated by heat, means for placing a protecting disk on top of and in contact with the cementing medium, and means for placing the parts of the closure under pressure and coagulating the cementing medium while the pressure is maintained.

5. In a machine for applying protecting disks to closures of the cap variety, the combination with means for applying to the exposed face of the sealing disk of the complete closure a suitable cementing medium adapted to be coagulated by heat, means for placing a protecting disk on top of and in contact with the cementing medium, and a heating plunger for placing the parts of the closure under pressure and coagulating the cementing medium while the pressure is maintained.

6. In a machine for applying protecting disks to closures of the cap variety, the combination with means for applying to the exposed face of the sealing disk of the closure a suitable cementing medium adapted to be coagulated by heat, means for placing a protecting disk on top of and in contact with the cementing medium, and a plurality of heated plungers acting in succession for placing the parts of the closure under pressure and coagulating the cementing medium while the pressure is maintained, the acting underface of the last plunger in the series

being plane and those of the others convex, whereby they flatten gradually the protecting disk.

7. In a machine for applying protecting disks to closures of the cap variety, the combination with means for applying a cementing material to the exposed face of the sealing disk of the complete closure, means for cutting a protecting disk from a strip and placing the same on top of and in contact with the cementing material, and means for applying pressure to the closure for maintaining said contact.

8. In a machine for applying protecting disks to closures of the cap variety, the combination with means for applying a cementing material to the exposed face of the sealing disk of the complete closure, means for cutting a protecting disk from a strip and placing the same on top of and in contact with the cementing material, and means for applying pressure to the closure for maintaining said contact and flattening the protecting disk.

9. In a machine for applying protecting disks to closures of the cap variety, the combination with means for applying a cementing material to the exposed face of the sealing disk of the closure, means for cutting a protecting disk from a strip and placing the same on top of and in contact with the cementing material, and a plurality of plungers acting in succession for applying pressure to the closure for maintaining said contact, the acting underface of the last plunger in the series being plane and those of the others convex, whereby they flatten gradually the protecting disk.

10. In a machine for applying protecting disks to closures of the cap variety, the combination with means for applying to the exposed face of the sealing disk of the complete closure a suitable cementing medium adapted to be coagulated by heat, means for cutting a protecting disk from a strip and placing the same on top of and in contact with the cementing medium, and means for placing the parts of the closure under pressure and coagulating the cementing medium while the pressure is maintained.

11. In a machine for applying protecting disks to closures of the cap variety, the combination with means for applying to the exposed face of the sealing disk of the complete closure a suitable cementing medium adapted to be coagulated by heat, means for cutting a protecting disk from a strip and placing the same on top of and in contact with the cementing medium, and a heating plunger for placing the parts of the closure under pressure and coagulating the cementing medium while the pressure is maintained.

12. In a machine for applying protecting disks to closures of the cap variety, the combination with means for applying to the exposed face of the sealing disk of the closure a suitable cementing medium adapted to be coagulated by heat, means for cutting a protecting disk from a strip and placing the same on top of and in contact with the cementing medium, a plurality of heated plungers acting in succession for placing the parts of the closure under pressure and coagulating the cementing medium while the pressure is maintained the acting underface of the last plunger in the series being plane and those of the others convex, whereby they flatten gradually the protecting disk.

13. In a machine for applying protecting disks to closures of the cap variety, the combination with means for applying a cementing medium to a portion of the exposed face of the sealing disk of the closure, means for cutting from a strip of material a protecting disk of a diameter smaller than that of the sealing disk and placing the same concentrically with the sealing disk on top of and in contact with the cementing medium, and means for applying pressure to the closure for maintaining said contact.

14. In a machine for applying protecting disks to closures of the cap variety, a pressure applying means comprising a plurality of plungers, the acting surface of at least one of said plungers being plane and those of the others convex.

Signed at New York, in the county of Kings and State of New York, this 7th day of June, A. D. 1916.

UNITED STATES PATENT OFFICE.

WILLIAM H. WHEELER, OF BALTIMORE, MARYLAND, ASSIGNOR TO THE CROWN CORK AND SEAL CO., OF BALTIMORE, MARYLAND, A CORPORATION.

APPARATUS FOR THE MANUFACTURE OF BOTTLE-CLOSURES.

No. 887,883. Specification of Letters Patent. Patented May 19, 1908.

Application filed September 20, 1905, Serial No. 279,349. Renewed October 3, 1907. Serial No. 395,760.

To all whom it may concern:

Be it known that I, WILLIAM H. WHEELER, a citizen of the United States, residing at No. 1511 Guilford avenue, Baltimore, Maryland, have invented certain new and useful Improvements in Apparatus for the Manufacture of Bottle-Closures, of which the following is a specification.

My invention relates to the manufacture of bottle closures of the class known as crown cork sealing caps or closures, and it concerns particularly a machine for uniting the compressible or resilient packing material to the metallic cap.

In carrying out my invention I employ heat to soften or fuse the protecting and binding medium located between the packing or sealing gasket and the metal cap and after the parts are thoroughly heated they are allowed to cool or subjected to artificial cooling, and during this time they are subjected to pressure so as to firmly unite the packing or gasket to the cap by the binding and protecting medium. During the heating action of the parts they are not subjected to pressure or to any action which would tend to confine any moisture or air which may be in the material or in the pit holes or crevices thereof or pocketed between the members of the closure, but on the contrary, the assembled parts are left entirely free for the escape of any moisture or for the escape of the air in expanding. The advantages of this mode of procedure and the means for carrying out the same will be set forth hereinafter.

I aim among other things to provide a construction for the uniting of the assembled members of the closure which may be added to existing forms of assembling machines, occupying no more floor space than is necessary to accommodate the existing form of machine. I have sought also to provide a compact arrangement, but at the same time one in which the heating action on the members of any one closure may be continued a sufficiently long time to thoroughly soften the binding material and to drive out any moisture or air in the material or between the members which might interfere with the firm uniting of the parts.

The invention consists in the features, combination and arrangement of parts hereinafter described and particularly pointed out in the claims.

In the accompanying drawings,—Figure 1 is a front view of a machine embodying my invention. Fig. 2 is a plan view of the heating table or steam plate showing also in section the spiral arranged above the plate for controlling the movement of the closures thereover and further, showing the chill ring surrounding the heating plate or steam table upon which the closures, together with their contents, are subjected to compression while being cooled. Fig. 3 is a sectional view through the heating table or steam plate together with the chill ring and compressing device with the parts associated with the elements named. Fig. 4 is a plan view of a portion of the heating plate and table with part of the chill ring also shown. Fig. 5 is a plan view of the housing for the plungers with the cam carried thereby illustrated in dotted lines. Fig. 6 is a sectional detail view of the housing.

The invention is shown in connection with the type of apparatus for making composite closures such as is disclosed in Letters Patent of the United States, granted to me August 29, 1905, #798549. In said apparatus the metallic caps, the collets of paraffin paper and the cork disks are assembled and are subjected to the action of suitable die mechanism which presses the component parts intimately together, compressing the sealing disk and mechanically uniting the parts by slightly contracting the vertical wall of the metallic cap or crown or by slightly reducing the diameter of the crown so as to cause it to grip and hold the cork or sealing disk in place therein. In the machine described in the said patent, after the parts have been assembled and united mechanically, as just described, they are discharged from the apparatus, but my present improvement contemplates uniting the metallic cap with its compressible contents or packing by fusing the interposed material, such for instance as the collet described, and subjecting the parts to pressure while cooling and while the binding or sealing material is hardening.

It is thought to be unnecessary to describe the assembling mechanism and the die mechanism as these parts are fully disclosed

in the patent referred to. After leaving the die mechanism the composite closure is discharged into a chute 1, Fig. 1, which directs the closure onto a heating table or steam plate 2. The cap as discharged upon this table is in inverted position resting with what is actually its top side on the table.

The heating table or steam plate is rotated, as will be hereinafter described, and it is provided with a series of ribs 3 of wedge shape, that is, increasing in width outwardly so as to provide a series of channels or grooves 4, between them which grooves are of equal width throughout their extent and are adapted to receive the closures or caps in inverted position to direct them to the outer edge of the table.

The closures as they are discharged from the end of the chute 1 enter between the ribs 3 and in position to be acted on by the downwardly projecting walls or ribs 5 of a plate 6, which is supported in fixed position as will be hereinafter described.

The walls 5 extend spirally and by acting upon the upturned flanges of the closure as the same is carried around by the movement of the heating plate, they cause the closures to move radially outward through the grooves or channels 4. During this outward movement the closures are subjected to heat from the heating table which being transmitted through the metal of the cap, directly in contact with the heating table, causes the binding and protecting material which is interposed between the compressible packing of cork or other material and the cap to be fused for the purpose of uniting the compressible packing with the cap and for other purposes as fully set forth in the Letters Patent of the United States #792284, granted June 13, 1905, to William Painter.

Surrounding the steam plate or heating table and moving therewith is arranged a chill ring $2^{\times}$, which is ribbed and grooved to form continuations of the ribs and grooves of the steam or heating table, the said chill ring being secured to the heating table by screws 7, Fig. 3, with asbestos packing 8 interposed to prevent the transmission of heat to the chill ring. This ring is subjected to cooling influences, as will be hereinafter described, and it is provided with a series of depressions 9, one in each of the grooves $4^{\times}$ which form continuations of the groove 4 of the heating table. These depressions are adapted to receive the closures and form a centering recess for the same to aid in holding the closure in place during the cooling of the parts and while they are subjected to pressure.

It will be seen that the closures as they traverse the heating table are free, not being subjected to pressure, and they follow each other through the grooves 4 closely, and during this time they are subjected to the heat from the heating table for which the spiral plate acts as a cover and serves to form, in connection with the surface of the heating table, a chamber in which the closures are subjected to the heat while free from pressure.

The spiral of the plate 6 continues to act on the closures until they are discharged at the point *a* Fig. 2 onto the chill ring, the spiral at this point having an abrupt outward bend in its walls and the depending wall having also a concentric portion 10, just beyond the point *a*, which by acting on the closure will move it into the depression 9. As soon as this takes place, and of course as soon as the metal cap of the closure contacts with the chill ring, the parts of the closure are subjected to the cooling action of the said chill ring, and while cooling is subjected to pressure. The pressure is exerted through a plunger, one for each of the depressions in the chill ring, said plungers 11 being guided in a casting of ring shape 12, having an inturned lower flange 13, and an inturned upper flange 14 through which flanges the plunger 11 is guided.

Each plunger is pressed normally downwardly by a spring 15 bearing upon the ring casting at the upper end and upon a collar 16 on the plunger at the lower end. Each plunger has an extension 17, carrying a roller 18, which is adapted to coöperate with a cam 19 supported on a casting or ring 20, which is fixed to brackets 21, which brackets are supported from a stationary portion of the machine as will be hereinafter described.

The plunger carrying ring rotates with the steaming or heating table and the chill ring, being connected to the said ring by screws 22. The said plunger carrying ring or casting has a circular row of teeth 23 on its inner side meshing with a gear wheel 24 which is driven as will be hereinafter set forth.

The stationary cam 19 for controlling the vertical position of the plungers and their action on the closure extends only a short way about the circular casting 20 to which it is attached, and in the revolution of the steaming table, chill ring and plunger-carrying ring the plungers are raised just before they reach the point at which the closures are discharged from the spiral and from the heating table onto the chill ring, and this permits the proper positioning of the closure beneath the elevated plunger, and when this has taken place the roller of the elevated plunger runs off from the stationary cam 19, thus allowing the plunger to fall and engage the packing placing the same together with the other parts of the closure under compression, and in this condition, and while in contact with the chill ring, the closure makes very nearly a full revolution, about the axis of the machine until the roller on the plunger again arrives

at the stationary cam 19 when the said plunger is again lifted and the closure with its parts united by the fusible material which has now been cooled and hardened, is discharged from the chill ring by coming in contact with the outwardly inclined edge 24 of the wing 25 forming a termination of the outer wall of the spiral, this wing with its inclined edge being located close to the point at which the closure is thrust upon the chill ring from the spiral so that nearly a complete revolution of the machine takes place during the time the closure is subjected to the cooling influences of the chill ring and to the pressure acting directly upon the compressible packing so that an effective hardening of the fusible substance will take place before the packing is released from its compressed condition, this being important in order to prevent the packing in resuming its uncompressed condition, from destroying the binding effect of the interposed fusible material.

Having described the general features and operation of the invention, certain details of construction and arrangement will be necessary to be disclosed in order to fully understand the same.

As will be seen from Fig. 1, the heating, cooling and pressure mechanism is arranged beneath the assembling and die mechanism of the machine above referred to and axially in relation thereto occupying no more floor space than is necessary for the said machine.

The heating table turns in a central bearing 26 of a frame or plate 27 which is supported by legs 28 from the floor. The heating table is formed in two parts joined by screws at 29 with interposed packing, the two parts forming a chamber into which steam is admitted by a pipe 30. The exhaust takes place through the hub 31 of the steam table and a pipe 32 extending into the said hub about the steam inlet pipe 30 from a casting 33 suitably supported on the floor and through which also the steam pipe enters. From this casting a discharge opening 35 directs the exhaust steam to any suitable point. A stuffing box is provided at 34 of any suitable construction.

The plate carrying the spiral and constituting a part of the heating chamber for the closures is provided with a covering of asbestos, as at 36, forming between itself and the plate an air space 37. This construction prevents the radiation of heat and asbestos may be applied at all necessary points to confine the heat to the heating chamber. It is also shown at 38 as a lining for the stationary frame or plate 27. This plate or frame has formed therewith an annular channeled portion made up of the inner and outer flanges 39, 40. In this channel is placed means for cooling the chill ring consisting of a pipe 41 for conveying the cooling fluid, such as water or compressed air, the said pipe having jet openings 42 to direct the fluid to the underside of the chill ring at or near the center, on each side of which the chill ring is provided with depending flanges 43 to better control the cooling fluid and cause it to act more thoroughly upon the chill ring. The cooling pipe is carried in a trough 44 held within the annular channel of the plate or frame 27, the said trough receiving the fluid after acting upon the chill ring and conveying it to a suitable discharge, as for instance, the outlet pipe 45, Fig. 1. The annular channel has also located therein a ball bearing arrangement for the steam table. This consists of a ring 46 having a series of openings for anti-friction balls 47, which balls are borne upon by a ring 48 attached by screws 48× to the steam table and said balls rest upon a ring 49 having a raceway therein for the balls, which ring is held adjustably by a screw 50 in a groove 51 of the plate or frame 27.

As before stated, the ring or casting for supporting the cam 19 and which also serves to house the rollers and plungers, is supported upon the brackets 21, and these brackets are secured by screws 52 to the outer side of the stationary plate or frame 27. These brackets 21 also have extensions 53 reaching down within the housing or ring 20, and by means of bolts 54 they support the spiral plate, before mentioned, in a stationary manner.

The housing 20 carrying the cam 19 for operating the plungers 11 is attached to the brackets 21 by the screws 59, 60. Anti-friction bearings are provided at the upper part of the rotating ring or casting 12 consisting of the anti-friction rollers 55 and 56, the latter of which turns on a part of the screw 57.

The connections for driving the heating table comprise besides the circular rack 23 and gear 24, the shaft 63, upon which said gear 24 is fixed, said shaft having its bearings in a bracket 64 secured to the main frame 65 of the table, the gear 66 on said shaft meshing with a pinion 67 on the shaft 68, which forms a part of the transmitting connection of the assembling machine, carrying thereon the bevel gears 69 and 70 meshing respectively with the bevel gears 71, 72, whereby the feed plate 73 of the assembling machine is driven from the main shaft 74 through the gearing 75, 76.

From the above it will be seen that the assembled parts of the closure are subjected to heat while in the condition in which they leave the dies of the assembling machine. In this condition the packing while frictionally held by the walls of the cap, is free from pressure or from contact with any device which might act to prevent the escape of the air or moisture from the crevices or from the

body of the material itself within the cap. It is desirable to allow the air and moisture, if there be any, to escape freely before the parts are subjected to pressure, for if the pressure takes place before or simultaneously with the heating, any air contained in the pit holes or crevices of the packing or between the members of the closure or any moisture present on or about the members, may, by expanding, tend to separate the parts and prevent them from uniting perfectly under continued pressure. Further, it will be observed that as a heating medium, I use steam and this is applied to the table over whose imperforate surface the crowns pass. There is thus no direct contact of the heating medium with the crowns and no damage results thereto. During the application of the pressure the cap rests firmly upon the chill ring and the plunger engages the packing without requiring or causing any change in the shape of the flange of the cap, said plunger being free to rise from the cap at any time.

The heating table occupies the space within the standards or supporting legs of the apparatus and by reason of the spiral course over which the closures are made to pass, the heat continues to act on the closures for a long time so as to thoroughly soften the interposed binding material and prepare the parts for the cooling and pressing action.

It will be understood that the fundamental principle underlying the organization of elements above described may be embodied in apparatus of different form from that disclosed herein without departing from the broad scope of my invention.

The rotary table serves both as a heating means and also as a means for imparting movement to the closures, which movement is controlled by the spiral so that they traverse the table radially outward.

The assembling mechanism may be the same as that disclosed in the patent above referred to or any other desired form may be employed.

I do not limit myself to the precise form of the elements herein described.

I claim:—

1. In an organization for uniting the metallic member of a bottle or like closure with its compressible packing having a fusible material interposed between it and said metallic member, means for heating the assembled members of the closures while free to allow the expanding air to escape, and means for pressing the parts together while cooling, substantially as described.

2. In an organization for uniting the metallic member of a bottle or like closure with its compressible packing having a fusible material interposed between it and said metallic member, means for heating the assembled members of the closures while free to allow the expanding air to escape, means for cooling the parts, and means for pressing the parts together while cooling, substantially as described.

3. In an organization for uniting the metallic member of a bottle or like closure with its compressible packing having a fusible material interposed between it and said metallic member, means for heating the assembled members of the closures while free from pressure to allow the expanding air to escape, and means for pressing the parts together while cooling, substantially as described.

4. In an organization for uniting the metallic member of a bottle or like closure with its compressible packing having a fusible material interposed between it and said metallic member, a plunger, a support on which the closure rests and between which and the plunger the closure is pressed, and means for heating the assembled parts of the closure for fusing the interposed material before the compression takes place said compression taking place during the cooling of the parts and the hardening of the interposed binding material, substantially as described.

5. In an organization for uniting the metallic member of a bottle or like closure with its compressible packing having a fusible material interposed between it and said metallic member, means for supporting the closure in inverted position, means engaging the packing and the cap or metallic member to press them towards each other, and means for applying heat to fuse the said interposed binding material before the inverted closure is subjected to pressure and while it is free to allow the escape of the expanding air, substantially as described.

6. In an organization for uniting the metallic member of a bottle or like closure with its compressible packing having a fusible material interposed between it and said metallic member, means for supporting the closure in inverted position, means engaging the packing and the cap or metallic member to press them towards each other, means for cooling the closure while subjected to pressure, and means for applying heat to fuse the said interposed binding material before the inverted closure is subjected to pressure and while it is free to allow the escape of the expanding air, substantially as described.

7. In an organization of the class described, means for pressing the parts of the closures together and means for heating the closures with their interposed fusible binding material, said heating means serving to move the closures to the pressing means, substantially as described.

8. In combination in apparatus of the character described, means for heating the closures with their interposed binding mate-

rial comprising a table, means for moving the closures outwardly over the said table while being heated, and means for receiving the outwardly moving closures and subjecting them to pressure to unite the parts, substantially as described.

9. In combination in apparatus of the character described, means for heating the closures with their interposed binding material comprising a table, means for moving the closures radially outwardly over the said table while being heated, and means for receiving the outwardly moving closures and subjecting them to pressure to unite the parts, substantially as described.

10. In combination in apparatus of the character described, means for heating the closures with their interposed binding material comprising a table, means for rotating said table, means for effecting the movement of the closures outwardly over the said table while being heated, and means for receiving the outwardly moving closures and subjecting them to pressure to unite the parts, substantially as described.

11. In combination, in apparatus of the character described, a table for supporting the closures, a guiding device over the table, one of said parts being movable to cause an outward movement of the closures in respect to the table, means for applying heat and means for receiving the closures when moved outward adapted to press the parts of the closure together, substantially as described.

12. In combination in an apparatus of the class described, a rotary table for supporting the closures, means over the said table for effecting in connection with the movement of the said table an outward passage of the closures over the table, means for applying heat, and means at the outer edge of the table for receiving and pressing the parts of the closures together, substantially as described.

13. In combination in an apparatus of the class described, a rotary table for supporting the closures, means over the said table for effecting in connection with the movement of the said table an outward passage of the closures over the table, means for applying heat and means adjacent the outer edge of the table for receiving and pressing the parts of the closures together, said pressing means revolving in unison with the table, substantially as described.

14. In combination in an apparatus of the class described, a rotary table for supporting the closures, means over the said table for effecting in connection with the movement of the said table an outward passage of the closures over the table, means for applying heat and means adjacent the outer edge of the table for receiving and pressing the parts of the closures together, said pressing means revolving in unison with the table and consisting of a circular series of plungers, substantially as described.

15. In apparatus of the class described, means for pressing the parts of the closures together, an imperforate table on which the closures rest, and means for applying heat to the said table, said pressing means being adapted to receive the closures from the said plate, substantially as described.

16. In apparatus of the class described, means for pressing the parts of the closures together, an imperforate table upon which the closures rest, means for applying heat to said table, and means for causing the closures to move over the said table outwardly to the pressing means, substantially as described.

17. In combination, in apparatus of the class described, means for pressing the parts of the closure together, a table having outwardly extending ways to direct the closures to the pressing means, means for causing the closures to pass outwardly through said ways, and means for applying heat, substantially as described.

18. In combination in apparatus of the class described, means for pressing the parts of the closure together, a table upon which the closures rest in inverted position, means for applying heat and a plate over the table forming between itself and the table a heating chamber, said pressing means receiving the closures from the table, substantially as described.

19. In combination in apparatus of the class described, means for pressing the parts of the closure together, a table upon which the closures rest in inverted position, means for applying heat and a plate over the table forming between itself and the table a heating chamber, and a spiral guide depending from said plate to engage the closures, said pressing means receiving the closures from the table, substantially as described.

20. In combination in apparatus of the class described, means for pressing the parts of the closures together, an imperforate table upon which the closures rest, a steam chamber beneath the said table for heating the same, said pressing means receiving the closures from said table, substantially as described.

21. In combination in apparatus of the class described, a rotary table having outwardly extending grooves or ways, a guide for causing the movement of the closures outwardly, and a series of plungers revolving in unison with the rotary table and receiving the closures from the rotary table, substantially as described.

22. In combination in apparatus of the class described, a series of plungers, means for previously heating and then delivering

the closures thereto, and means for positively discharging the closures from in front of the plungers, substantially as described.

23. In apparatus of the class described, a revolving series of plungers, means for previously heating and then delivering the closures thereto and means for discharging the closures from beneath the plungers at one point, substantially as described.

24. In apparatus of the class described, a revolving series of plungers, means for previously heating and then delivering the closures thereto and means for discharging the closures from beneath the plungers at one point, said means consisting of the incline in the path of movement of the closures, substantially as described.

25. In combination in apparatus of the class described, means for heating the closures while free from pressure, chilling and pressing means, and means whereby the closures are delivered from the heating means to the chilling and pressing means, substantially as described.

26. In combination in apparatus of the class described, means for heating the closures while free from pressure, chilling and pressing means for receiving the heated closures from the heating means, said pressing means acting to press the parts of the closure together between itself and the chilling means, substantially as described.

27. In combination in apparatus of the class described, means for heating the closures while free from pressure, a chill plate and plunger for receiving the heated closures for cooling and uniting the parts thereof, said plunger pressing the closures between itself and the chill plate, substantially as described.

28. In combination in apparatus of the class described, a table, means for applying heat, a chill ring surrounding the table to receive the heated closures therefrom and means for pressing the closures to unite the parts thereof while cooling on the chill ring, substantially as described.

29. In combination, in apparatus of the class described, a plate having outwardly extending ways or grooves, a chill ring surrounding the plate and having ways forming continuations of those of the heating plate, and plungers for pressing the closures while on the chill ring to unite the parts while cooling and during the hardening of the binding material, substantially as described.

30. In combination in apparatus of the class described, a rotary table, means for applying heat, means for causing the closures to move over the surface of said table outwardly, a chill ring surrounding and revolving with the said table and receiving the heated closures therefrom, and means for pressing the closures to unite the parts thereof while cooling upon the chill ring, substantially as described.

31. In combination in apparatus of the class described, a rotary table, a concentric chill ring, said table and ring having their surfaces in the same plane, means for delivering the closures from the table onto the chill ring, and means for pressing the closures on said chill ring, substantially as described.

32. In combination in apparatus of the class described, a rotary table, a concentric chill ring, means below the table and ring for heating and chilling the same respectively, means whereby the closures are delivered from the heated table to the chill ring and means for pressing the closures while on the chill ring to unite the parts thereof, substantially as described.

33. In combination in apparatus of the class described, means for heating the closures while free from pressure, a chill support having a depression to receive the closures, means for moving the closures into said depressions, and means for pressing the closures while in said depressions, substantially as described.

34. In combination in apparatus of the class described, a heating table, a chill ring surrounding the same, a series of plungers over the chill ring, means over the table for moving the closures outwardly onto the chill ring and for centering the same beneath the plungers, substantially as described.

35. In combination in apparatus of the class described, a heating table, a chill ring surrounding the same, a series of plungers over the chill ring, means over the table for moving the closures outwardly onto the chill ring and for centering the same beneath the plungers, said heating table, chill ring and series of plungers having revolving movement and means at one point for discharging the closure from the chill ring after being pressed to unite the parts of said closure, substantially as described.

36. In combination in apparatus of the class described, a rotary heating table, a chill ring surrounding the same and rotating therewith, a series of plungers rotating with the chill ring, means for delivering the closures from the heating table onto the chill ring, means for discharging the closures after being pressed to unite their parts, said discharge taking place at a point adjacent the delivery point of the closures onto the chill ring, means for lifting the plungers at the discharge point, and means for lowering them at the delivery point and holding them lowered during the greater portion of the revolution of the parts, substantially as described.

37. In combination with the assembling machine, apparatus for uniting the parts of the closures and means for directing the

closures from the assembling machine to the said uniting apparatus, said assembling machine being superimposed in relation to the uniting apparatus, substantially as described.

38. In combination in apparatus of the class described, the table for supporting the closures, heating means, a spiral guide over said table and means for receiving the closures from the said table to press them and unite the parts, substantially as described.

In testimony whereof, I affix my signature in presence of two witnesses.

WILLIAM H. WHEELER.

UNITED STATES PATENT OFFICE.

WILLIAM PAINTER, OF BALTIMORE, MARYLAND, ASSIGNOR TO CROWN CORK AND SEAL COMPANY OF BALTIMORE CITY, OF BALTIMORE, MARYLAND.

MACHINE FOR MAKING CLOSURES FOR BOTTLES AND THE LIKE.

No. 887,838. Specification of Letters Patent. Patented May 19, 1908.

Application filed May 24, 1905, Serial No. 262,048. Renewed October 3, 1907. Serial No. 395,758.

To all whom it may concern:

Be it known that I, WILLIAM PAINTER, a citizen of the United States, residing at Baltimore, Maryland, have invented certain new and useful Improvements in Machines for Making Closures for Bottles and the Like, of which the following is a specification.

In certain applications for patent filed by me June 6, 1902, (Serial No. 110,535) and September 29, 1902, (Serial No. 125,180) I disclosed certain novel methods or processes of manufacturing bottle closures, wherein a special feature involves the interposition of a suitable fusible protecting amd binding medium between a suitable metallic cap and a suitable sealing gasket or packing; then properly heating the cap, gasket and said medium, and meantime subjecting the whole to appropriate pressure, and while still under such pressure, cooling the completed closure.

My present application discloses certain novel mechanism, both in detail and in organization, as devised by me for the manufacture of bottle closures in harmony with my said novel method, and with special view to economically producing closures involving sundry novel characteristics of substantial value. A reliably firm union of the metal with the packing is assured, which contributes to substantial economy, because the packing, whether in the form of rings or disks, can be not only thinner, but of less diameter than heretofore, and such open pits or holes as are common to cork are well closed next to the metal, and the cork itself, although quite well condensed has highly effective resiliency. Liquid can seldom if ever reach back of the packing when the closure is in use on a bottle, and the central portion of a disk packing is so firmly held as to prevent undue inward bulging.

After a detailed description of my present invention in connection with the accompanying two sheets of drawings, the several features deemed novel will be duly specified in the several clauses of claim hereunto annexed, it being understood that the machine here illustrated is adapted to operate in connection with closures of the well known "Crown cork system."

Referring to the drawings, Figure 1 illustrates, mainly in plan view but partially in section an organization embodying my present invention. Fig. 2 is a vertical section of the parts shown in Fig. 1 on the irregular line *x*—*x* (but on a somewhat reduced scale) and also certain overlying parts, some in side or edge view, and others in section. Figs. 3 and 4, on an enlarged scale, and in two successive positions, illustrate an appropriate pressure block with a plunger and a die, which coöperate in effecting a temporary mechanical union of each presser block with a cap and its packing, and also the desired compression of the contents of the cap. Fig. 5 is a side view of a presser block and the end of the arm on which it is carried. Fig. 6, in section on line *y*—*y* Fig. 1, illustrates a cork carrier and its hub or journal, an underlying portion of the frame of the machine, and an overlying plate or cover, not shown in Figs. 1 or 2. Fig. 7 illustrates in elevation and vertical cross section a heating apparatus, and also in side view an overlying presser block holding a filled closure in proper position to be heated. Fig. 8 illustrates in side view, a cam wheel and a bell crank lever carrying a clearer for detaching finished closures from the presser blocks. Fig. 9 is a detail view of the clearer for releasing caps from the presser blocks.

Believing it will be conducive to a prompt comprehension, to first indicate in a general way the salient parts of the machine and its mode of operation, I will state, specially referring to Fig. 1, that a fixed table 1 receives metal caps already provided with a suitable interior binding medium; an attendant arranges them open side up and slides them upon an exposed portion of a continuously revolving feed table 2, partially covered, as at 4 and 5, so as to afford near the periphery of the table a curved race-way or channel 3. The caps are frictionally carried through this channel until they reach its end at a circular space occupied by an intermittently operated star wheel 7, overlying a portion of the feed wheel, and having between its arms, semi-circular spaces or pockets 6 adapted to receive the caps one by one from the channel 3 and carry them in a circular path beneath an intermittently operated cork wheel or carrier 10. This carrier receives the packing from above regardless of its form, (*i. e.*, sometimes ring shaped, but generally in disk form,) at 25 and delivers the packing at 9, where a cork plunger forces it downward into an underlying cap still within the custody of the star wheel 7, which then carries the filled caps one by one in a circular path beneath a

vertical presser block plunger 26 to, over, or into, a cooperating stationary die. An intermittingly operated circular table, here termed a "timing" table, carries at its periphery a series of equidistant circular presser blocks 29 on the under sides of spring controlled radial arms 30, so that when a cap with its packing stops at the die and plunger 26, the latter will force the presser block into the cap, upon the packing, and carry the cap into the die until appropriate pressure has been assured. The die being of slightly less diameter than the caps, the flange of each is peripherally reduced and made to tightly engage with a presser block, and when released from the die, it is carried by the presser block with the binding medium and packing more or less heavily compressed, because of the firm (but temporary) mechanical union of the cap and presser block. The timing table by its intermittent movement first presents each presser block and the closure thereon to a heating apparatus at 41, for fusing the binding medium, and from thence, to the cooling apparatus at 43', and after having been properly cooled and the binding medium hardened, the finished closures or "crowns" are automatically released from the presser blocks by a clearer at 49.

Now as to a more specific description, it will be seen in Figs. 1 and 2 that the feed table 1 is continuously rotated by way of a vertical shaft 55, bevel gears 54 and 53, a horizontal shaft 52, bevel gear 51, and an overlying horizontal bevel gear 50 on a spindle pendent from the table and carried in a hanger at a portion 47 of the frame. The central cover 4 of the table, and the curved cover plate 5 with the intervening channel 3 have already been referred to. For working upon plain "crowns" the surface of the table may be of metal, hard paper, or wood, but for decorated crowns it will sometimes be desirable to have a softer covering, such as leather, to avoid scratching the decorations.

The star wheel 7 has multiple functions, and hence it is difficult to specially designate it in harmony with its duties. It not only takes unfilled caps one by one from the feed table and carries them to the cork feeder 10, but it also operates with its teeth 58 as a sprocket or gear in driving said feeder, step by step, and still further in like manner with its pockets 6 delivers filled caps to the die, and drives the timing table. The star wheel shaft 8 is intermittently driven by its worm gear 56, actuated from the adjacent continuously driven shaft 66, by means of a cam 57 having a spline or worm which operatively engages with the worm gear long enough to impart required movement to the star wheel, said spline being so shaped, (*i. e.*, straight and curved,) as to afford the required rest during the remainder of its own rotation in a manner well known. These parts are similar to those described in Letters Patent of the United States granted to Wm. H. Wheeler 798549 August 29, 1905.

The cork wheel, or feeder 10, shown in section in Fig. 6, is horizontally journaled on top of a circular bearing plate 21', having a hub or post 21 mounted upon and doweled, as at 23, to a portion of the frame of the machine and held down by a clamp screw 22 which also controls a cover 61 which is not indicated in Figs. 1 and 2, and may or may not be used. The cork wheel is composed of a heavy bottom plate 19 provided with a rabbeted flange, and an attached thin top plate which rests upon the bearing plate 21'. This top plate is provided with an annular series of circular holes 20, which register with corresponding holes 18 in the bottom plate 19 whenever in the course of rotation they register with a similar single hole 24 in the bearing plate 21, at which point the cork plunger 9 performs its duty. Except at this one point, the bearing plate serves as the bottom for all the holes 20, and enables them to serve as pockets for packing disks delivered thereto from the overlying cork tube 25, Fig. 2. This cork tube is vertically slitted at one side and is provided with a weight 25' having a projected finger piece for enabling it to be lifted from the tube when a fresh supply of cork is needed, said weight assuring a proper delivery of corks from the bottom of the pile in the tube, one by one, into each pocket 20 as it passes below.

Adjacent to the tube 25 there is a hinged finger 67 connected with an electric signal (not shown) for announcing any failure of delivery of cork to a pocket, but this constitutes no part of my present invention. At each hole in the bottom plate, there is a pendent boss or flange 59, serving as a gear tooth for engagement by the star wheel as indicated at 60, Fig. 1.

The conveyer or timing table 31 is rotated step by step on its pintle 32 on a hanger 33 and is provided with a series of radial arms 30, strongly hinged, projecting from its periphery, and each normally maintained in an elevated inclined position by a spring 62. Each of said arms carries below its outer end a pendent presser block 29, frusto-conical in form, larger at its face than at the arm, and of appropriate size to properly enter a filled cap and bear upon the cork disk or packing and to be itself firmly engaged by the flange of the cap after the packing has been compressed, thus enabling the presser block to maintain desired pressure on the packing until the finished closure is finally released therefrom. As already indicated the presser block arms 30 also serve as teeth engaged by the star wheel in actuating the timing table.

The cork plunger 9 is mounted on a lateral arm 11 projecting from beneath a slide 12 (in guide bearing 13 on cross bar 14), which

also carries the presser block plunger 26, all simultaneously vertically reciprocated by means of a stud 17 in a cam groove 16 in a cam wheel 15 on the shaft 66, said groove being so shaped as to cause the plungers to operate when the cork wheel, the star wheel and the timing table are at rest.

The presser block plunger 26 coöperates with the underlying die 27 (on bed plate 28) containing a die block 34 which serves as a slidable bottom for the die, and has a pendent spindle 37 within a spiral spring having its thrust bearing at the top against a collar, and at the bottom on a tubular screw-threaded support or plug 39 (in a hanger 38,) which contains the lower end of the spindle and also an underlying stop screw 40.

It will now be obvious that the organization of the presser block plunger, the presser blocks with their arms, and the die, is such, that when a filled cap has been delivered to the die, as shown in Fig. 3 beneath a presser block, the plunger will descend, force the block into the cap, and drive it into the die and firmly lock the cap 36 to the block with the packing properly compressed, and that the extent of condensation can be predetermined by an adjustment of the stop screw upon which the block spindle abuts.

The spring in yielding, assures a gradual application of pressure, and in some cases it may be relied upon for limitation, but its prime function is to enable the die block to act as an ejector for promptly releasing a cap and presser block from the die, and it being adjustable its inevitable weakening can be compensated. The extent to which the cap may be forced into the die is also positively controlled by the stop screw 40, thus enabling variations as to the contraction of the flange of a cap and also as to the tenacity of its union with a presser block.

As to the heating apparatus 41, it is to be understood that it may be widely varied without departure from the main feature of my invention. The heat may be derived from electricity, steam, or combustion either within or flaming from the heater; but however heated the organization of the heater with the timing table should be such as to appropriately heat the caps on the loaded presser blocks during their progressive movement, and in each case appropriate to special conditions involved; as for instance, some packing and some form of binding medium, and some materials or compounds thereof, will require more heat than others, or less heat with varied extent of exposure, and plain crowns may be safely exposed to heating conditions which might be ruinous to decorated crowns.

As here shown, specially in Fig. 7, the heater 41 consists of a horizontal flat topped chamber 42 supplied with gas and air (on the Bunsen plan) by way of the vertical pipe 43 provided with a suitable sleeve for controlling the air mixture, and with a suitable cock for graduating the supply of gas or cutting it off. The flat burner top 44 has suitable jet apertures 45. A pilot burner (or ready lighter) 65 with its jets at 63 receives gaseous mixture from a small chamber 64 concentric with the main burner. For maintaining a proper control of the heat and the adjacent air currents induced thereby, the burner has adjacent vertical side walls which, while permitting more or less air to freely rise from below the burner, also guard against undue lateral disturbance as from drafts of air.

As to the cooling operation in the organization, it is to be understood that under some circumstances and with some materials requiring but little heat, it will only be necessary to provide for the transit of the heated closures beyond the heater for a long enough time to enable them to be cooled by the atmosphere at normal temperature before they are released from the presser blocks. For meeting all requirements however, an artificial cooling operation is important. The packing is quite heavily compressed, and air largely excluded from the cap, and hence with a heavy solid binding medium to be fused or softened, or one containing volatile matter, considerable heat would have been needed, and if such heat were not thereafter promptly checked or reduced, the packing or said medium or both, might be injured, and should the release of the closures from the presser blocks precede a proper hardening of the binding factor, and a proper cooling of the packing, the latter in expanding from a condensed condition might largely derange the union of metal and packing. As here shown, the cooler consists of a curved pipe 43′ on an arm 44′ and provided with vertical jet tubes 45′ in the path traversed by the crown laden presser blocks. Air, preferably under considerable pressure, is delivered to the cooler, so that on emerging in small jets it will promptly expand and induce a low temperature while directly impinging against the crowns when at rest, as well as during their movement.

In view of the falling tendency of cold air, it will be found sometimes advisable to provide an additional set of cooling jets located above or at one side of the path for delivering air inwardly or downwardly upon the crowns and blocks, which latter are liable to get unduly heated. To guard against such undue heating, the presser blocks may be provided with cores of wood, or other good non conductor of heat, the rims being of hard metal sufficiently smooth and strong to withstand the heavy grasp of the cap flanges, and admit of ready release.

The releasing of the caps from the presser blocks may be variously effected without de-

parture from my invention. The clearer 49, as indicated in Figs. 8 and 9, is intermittingly actuated from the horizontal shaft 66 by a cam wheel 48, and a bell crank lever 46 pivoted at 47, the lever at its upper end having a roller stud within an appropriate cam groove, (shown in dotted lines,) assuring the proper vertical reciprocation of the clearer, which overlies the edge of a crown on any presser block standing at rest at the point of clearance.

Having thus described my invention I claim,

1. In an organization for uniting the metallic member of a bottle or like closure with its compressible packing having a fusible material interposed between it and said metallic member, means for engaging the packing to press the same against the metallic member with the fusible material interposed, and means for subjecting said parts to a change in temperature, said change in temperature being maintained while the said packing is maintained under compression, substantially as described.

2. In an organization for uniting the metallic member of a bottle or like closure with its compressible packing with fusible material interposed, heating means and means for engaging the packing to hold it under compression while the closure is cooling, substantially as described.

3. In an organization for uniting the compressible packing with the metal caps of bottle closures, means for heating the metal caps with the contained packing and interposed fusible material, and means for subjecting the packing to compression, and during said compression subjecting the metal cap to a cooling action, substantially as described.

4. In an organization for making bottle closures of the cap variety, the combination, substantially as hereinbefore described, of means for automatically assembling the metal caps and packing, means for heating the caps, and means for subjecting the packing to pressure to hold it in proper position against the cap and the interposed fusible material while cooling, substantially as described.

5. In an organization for making bottle closures of the cap variety, the construction substantially as hereindescribed, consisting in means for automatically assembling the caps, the packing and the interposed material, means for heating the parts to fuse the binding material, and means for holding the packing under pressure within the cap while the parts are cooling and the binding material is hardening, substantially as described.

6. In combination, means for heating the assembled closure members and means for pressing the said members together and holding the said members under this pressure and while cooling, the said means of compression being movable to convey the closure while its members are maintained under pressure, substantially as described.

7. In an organization for making bottle closures of the cap variety, the combination substantially as hereinbefore described, of means for heating caps containing a compressible packing and an interposed binding medium, means for maintaining pressure thereon during the heating operation, said means entering the cap and engaging the compressible packing, and means for automatically controlling the caps during and after the heating operation.

8. In an organization of the character indicated, the combination substantially as hereinbefore described, of means for heating caps having compressible material therein, means for artificially cooling them, and means for maintaining the contents of the caps under compression during the heating and cooling operations.

9. In an organization for uniting the metallic member of a bottle or like closure with its packing, means for pressing the packing into said metallic member, and means for subjecting the said parts to heat while maintained under pressure, substantially as described.

10. In combination, means for pressing together the members of a bottle or like closure, means for first subjecting said members to heat while maintained under pressure and then to cooling influences while maintained under pressure, substantially as described.

11. In combination, means for pressing the members of a bottle or like closure together and for holding the said members under this pressure, means for heating the members while under said pressure, the said means for compression being movable to convey the closure while its members are maintained under pressure, substantially as described.

12. In combination, a heating apparatus, a conveyer having means for holding the members of a bottle closure together under pressure, said conveyer being arranged to carry the closure while its members are maintained under pressure to said heating apparatus and to carry the said members maintained under pressure away therefrom, substantially as described.

13. In combination, heating apparatus, a conveyer having means for holding the members of the closure together under pressure, said conveyer being arranged to carry the closure while its members are maintained under pressure to said heating apparatus and to carry the said members maintained under pressure away therefrom, and means for discharging the closure from the said conveyer, substantially as described.

14. In combination, a pressure plunger,

means for feeding the closures beneath the same to be pressed, and a movable pressure maintaining conveyer to carry the compressed closure from beneath the plunger while maintaining it under pressure, substantially as described.

15. In combination, a pressure plunger, means for feeding the closures beneath the same to be pressed, a conveying device movable beneath the plunger and a die for attaching the closures under pressure to said conveying device, substantially as described.

16. In combination, a pressure plunger, a conveying device provided with presser blocks arranged to move over the closure to be pressed and under the pressure plunger, and a die for crimping the flange of the closure to the presser blocks for attaching the same thereto and maintaining the members of the closure under pressure, substantially as described.

17. In combination, a pressure plunger, a conveying device movable beneath the same and over the closure to be pressed, said conveying device carrying the closure under pressure from beneath the pressure plunger, and a heating device to which the closure is conveyed while maintained under pressure, substantially as described.

18. In combination, a pressure plunger, a conveying device provided with frusto-conical presser blocks arranged to move beneath the pressure plunger and over the closures to be pressed and a die for crimping the flange of each closure on to a presser block, substantially as described.

19. In combination, a pressure plunger, a cooperating die having a spring controlled die block therein and a conveying device provided with a presser block, whereby said pressure block with a closure under pressure will be released from the die and carried away therefrom, substantially as described.

20. In combination, a pressure plunger, a star wheel having pockets or spaces between its arms for carrying crowns beneath the pressure plunger, a conveyer and presser blocks carried thereby to receive the crowns under pressure, the said conveyer being operated by the movements of the star wheel, substantially as described.

21. In combination, a pressure plunger, a star wheel, a conveyer having pressure maintaining means, arms on the conveyer for holding said pressure maintaining means, said arms meshing with the pockets of the star wheel, substantially as described.

22. In combination, a die on which the closures are placed, and pressure maintaining means on to which the closure is pressed by the action of the die, to be held under pressure, substantially as described.

23. In combination, a presser block for holding a crown closure with its packing disk under pressure, and means for placing the crown under pressure thereon.

24. In combination, a presser block for holding a crown with its packing disk under pressure, and means for placing the crown thereon under pressure, consisting of a plunger and a die, substantially as described.

25. In combination, a presser block for holding a crown with its packing disk under pressure, a die and a plunger, said plunger and presser block being movable towards and from the die, substantially as described.

26. In combination, a presser block having a peripheral surface adapted to enable a crown to be gripped thereon under pressure, and means for connecting the crown with the presser block.

27. In combination, a device for holding a crown with its packing disk under pressure, and means for placing the crown with its disk carried by said holding device and maintaining the contents of the crown under pressure while uniting them, substantially as described.

28. A machine for making closures for bottles and the like, comprising means for uniting the crowns with their disks and for holding them under pressure during that operation.

29. A machine for making closures for bottles and the like comprising means for uniting the crowns with their packing disks and for conveying and holding them under pressure during the uniting operation.

In testimony whereof, I affix my signature in presence of two witnesses.

UNITED STATES PATENT OFFICE.

WILLIAM PAINTER, OF BALTIMORE, MARYLAND, ASSIGNOR TO THE CROWN CORK AND SEAL COMPANY, OF BALTIMORE, MARYLAND, A CORPORATION OF MARYLAND.

METHOD OF MANUFACTURING BOTTLE-CLOSURES.

SPECIFICATION forming part of Letters Patent No. 792,284, dated June 13, 1905.

Application filed June 6, 1902. Serial No. 110,535.

To all whom it may concern:

Be it known that I, WILLIAM PAINTER, of the city of Baltimore, in the State of Maryland, have invented a certain new and useful Method or Process of Manufacturing Bottle-Closures, of which the following is a specification, taking in connection therewith the accompanying drawings, intended to contribute to a proper disclosure of my invention.

My present invention specially relates to the manufacture of such "bottle-closures" as are semimetallic and are accurately described (and classed) as "crown cork sealing-caps" or "closures," the same having been devised by me and originally disclosed in United States Letters Patent Nos. 468,226, 468,258, and 468,259, issued to me February 2, 1892.

While I am well aware that my invention, broadly considered, will afford substantial value in all operations wherein it is now or hereafter may prove to be specially desirable to adhesively unite any compressible and semi-resilient material to metallic surfaces, I have developed said invention only in the manufacture of said semimetallic gas-tight bottle-closures, and hence I will confine this specification to a description of operations in that special art and duly restrict my claims thereto.

The principal objects sought through my present invention are to enable the production of bottle-closures of the aforesaid class in such a manner as will practically assure reliable results in bottling under gaseous pressure; also, to prevent bottled liquids from taint by contact with the metal of the cap and the incident corrosion of the metal; also, to assure a reliable union of the caps with the coöperating sealing or packing disks or gaskets therein, whether said packings or gaskets be in the form of disks or annular and whether composed of cork or any suitable substitute therefor, and also to enable the production of such closures with uniformity in greater perfection and with greater facility and at a cost substantially below that involved in any prior method practiced by or known to me.

Broadly stated, my novel method or process consists, first, in interposing a suitable fusible protecting and binding medium between the packing or sealing disks or gaskets and the coincident inner surfaces of the metal coöperating therewith and of which the crown-caps are composed; secondly, while the caps, disks, and fusible binding medium are properly heated for fusing said medium subjecting the whole to appropriate pressure, and, thirdly, while still heated and the packing held under controlling pressure hardening the binding medium or permitting it to harden by cooling it, the disk, and cap. Inasmuch as the slow cooling of these parts precludes many of the valuable economic advantages accruing from hardening the fused medium as promptly as possible, one feature of my invention consists (in this final step) in subjecting the cap, disk, and fused binding medium to artificial cooling influences for promptly cooling them while under controlling pressure.

Referring to the drawings, Figure 1 illustrates the surface of a piece of sheet metal, to one portion of which the binding and protecting medium has been applied as a surface coating, another portion having said medium applied thereto in circular spots. Fig. 2, in side and edge views, illustrates a paper collet charged with said binding and protecting medium. Fig. 3, in side and edge views, illustrates a packing-disk. Fig. 4, in side view, illustrates a raceway in which the caps, disks, and binding medium are suitably compacted, maintained under pressure, heated, and cooled, all during a progressive movement. Fig. 5 is a cross-section of the compressing end or part of the raceway on line $x\ x$ with a cap, disk, and presser-block in section, as when entering the raceway. Fig. 6 is a similar cross-section of the pressure-maintaining portion of the raceway on line $y\ y$ and showing a cap and disk in section over the heater. Fig. 7 is a side view of one of the presser-blocks; and Fig. 8 illustrates in edge view, partly in section, a finished bottle-sealing closure.

In the clause broadly describing the first step in my method or process I have employed the word "interposing," meaning thereby

that it is immaterial for the purposes of this invention in what manner the fusible protecting and adhesive medium is or may be applied or interposed between the packing-disks and the metallic surfaces where it is to perform its intended functions—as, for instance, I have applied said medium to the sheets of tin from which metal is initially cut and formed into caps, so that their interior surfaces are thereby well and properly coated. I have also applied the medium to such sheets in circular spots at those points at which the initial cuts are to be made; also applied the said medium to the interior of formed caps; also interposed paper collets well charged with the medium; also applied said medium to the inner or rear surfaces of the cork disks, gaskets, or packing. In these so far recited interpositions said medium has been in the form of solution well dried after application. Outside of solutions I have further applied said medium in a pulverulent form, dusted upon the interior surfaces of the caps, which are then ready to receive their sealing-gaskets, and, still further, said medium in the form of a film cut in circular or other shapes and interposed between the metal surfaces and the gaskets. It will now be evident that whether the caps are "born" (as indicated) with the fusible protecting and adhesive medium therein or said medium be afterward applied and so that it may perform its complex functions the first step in my method or process will be involved in the appropriate assemblage of the caps, fusible medium, and sealing disks or gaskets. The best results thus far attained by me have accrued from the use of gum-shellac in alcoholic solution, it being understood that one, two, or more of the stated interpositions may be employed, according to the exigencies involved—as, for instance, the greater the corrosive tendency of a bottled liquid the greater the need for extra protection of the interior surface of the cap as against possible contact of such liquid, and the same or similar extra protection should be provided for liquids containing a high percentage of alcohol, which is a solvent of the preferred protecting medium. Special protection will be effective, for instance, by a direct coating on the metal, and in addition by way of the collet, and even still further with the coating on the disk or packing. The variations in quantity of the protecting medium thus interposed call for proportionate care in the application of the fusing heat during the second step of the process, as will be hereinafter more fully indicated.

Referring now to the drawings, in Fig. 1 a piece of sheet metal A is shown with one portion *a* thereof having its surface wholly coated with the protecting medium, and at another portion thereof, as at *b*, said medium is applied (as shown on a small scale) only in circular spots *b' b'*, &c., these being of proper size and appropriately located to enable the desired metallic caps (such as shown in Fig. 8) to be cut and formed from the metal so coated. As between these two applications of such medium there is involved an economy in favor of the "spots" in avoidance of waste in the coating which goes with the waste metal when the sheet is wholly coated; but in both cases not only is the inner top surface of the cap coated, but also the inner surface of its flange. The paper collet B of Fig. 2 is not only usually filled or charged with said medium, but it may be and is sometimes coated on both of its faces b^2 b^2. The packing-disk C of Fig. 3 has when needed its inner face b^3 coated with said medium.

I am aware that for the technical requirements of this specification there need be mentioned only a single type of suitable fusible protecting and binding medium; but with a view to an appropriate guidance to persons skilled in gas-tight bottle-closures and in the art of bottling I deem it proper to state that during my extended experience in this art I have used such gums as copal, sandarac, dammar, kauri, &c. I have, however, found no gum so reliably free from objectionable odor and taste and so safely worked in fusing as gum-shellac applied in alcoholic solution, although I find a close rival therewith in the best forms of Egyptian asphaltum in aromatic benzol solution.

Having proceeded as thus far described the assembled disks, caps, and binding medium, with or without the collets, are compressed and heat applied to the exterior surface of each cap in accordance with the second step in my process. The degree of compression may be varied according to specific requirements—as, for instance, pressure being always applied against the exposed or working face of the disk it should always be sufficient to cause the disk to closely conform to the sectional contour of the top of the cap and usually caused to lie snugly against the flange thereof. If the disks be of sliced cork (as distinguished from cork compound) and previously compressed for crushing hard spots therein, the pressure of this step need only be as already indicated; but if said disks should require "crushing" after the assemblage described then a heavier pressure would be appropriate. Such heavy pressure having been applied, it might or might not be further maintained, provided enough compression be continued to secure the effect of the lighter pressure, as hereinbefore indicated. The so assembled and compressed parts being then exposed to heat, it is immaterial in this step how the heat may be afforded or applied, provided a fairly perfect control of temperature is involved or an equivalent control of the time of exposure thereto. If unduly heated or for too long a time, the fusible medium may be caused to boil and to

exude toward the working face of the disk, as when much of said medium is employed, or with lesser quantity thereof to burn or coke it, and so render it useless, with a further liability of injury to the disks, and especially if the latter be of a composite type containing fusible material. I have employed with good results an electric heating-table which can be quite evenly maintained at a given temperature and upon which the closures may rest and be moved, the time or duration of exposure being relied upon for gaging as to safety. The simplest, safest, and most effective heating has, however, been attained by me by the use of suitable smokeless gas-flames, which being readily gaged as to volume enable an accurate and safe determination as to required time for exposure appropriate to the fusible medium, as well as the packing-disk, according to kind and quantity of fusible matter and variety of disk in each lot of closures. It will be obvious that in proceeding with this second step of my process it will be immaterial as to whether or not the heating and compression be initially simultaneous—as, for instance, the heating could be (and has been by me) begun before pressure was applied to the disks without materially affecting the results sought—although I deem it preferable to have pressure slightly precede the heating for better enabling the proper seating of the disks in the caps. During the compression of the disk the flange of the cap may be simultaneously slightly forced inwardly against the edge of the disk, as has been practiced by me; but it is to be understood that my present invention does not depend upon any accompanying mechanical action upon the cap-flange.

As hereinbefore indicated, the third or final step in my process involves, essentially, the hardening of the fusible medium while it, the packing-disk, and the cap are maintained under the appropriate pressure of the second step, and I will now refer to the drawings and describe the simple appliances selected for illustrating the operations involved in said second and third steps.

In Fig. 4 that which I have herein termed a "raceway" embodies two foot-rails D and D′ in the same horizontal plane and separated by a space somewhat less than the least diameter of the caps to be supported thereon with tops downward. Above said rails is an overlying head-plate E, symmetrically grooved at its under side centrally and longitudinally and in line with the center line of the space between the foot-rails. The rails are coupled and braced at intervals by underlying bow-shaped tie-braces d, and the head-plate is supported by and coupled to the foot-rails by vertical outwardly-curved posts or ties d' d'. This head-plate E is horizontal and parallel with the rails except at its ends, both of which are inclined upwardly, the end at e being the entrance to the raceway. The groove e' in the under side of the head-plate is concave in cross-section, as clearly indicated in Figs. 5 and 6. Beneath a portion of the raceway, near its entrance, is a suitable gas-burner F, controlled by a suitable cock f, and beneath another portion, beyond the gas-burner, is an air-chamber G, provided with a series of small vertical jet-pipes g, through which air is delivered upwardly after having been previously compressed and cooled by well-known means, which it is deemed unnecessary for the purposes of this specification to show or particularly describe. The delivery of the air through the jet-pipes is controlled by a cock g'. With this raceway a set of press-blocks H (in a desirable form) are employed, each having a globular head h, (for properly occupying and sliding in the groove e',) a circular base h', (about as large as a packing-disk,) an enlarged contact-rim h^2, and a groove h^3 between said rim and base, as shown in Figs. 5, 6, and 7. The height of each of these blocks H is so proportioned that when placed upon a disk packing C, within a metal cap I, the whole will freely enter the raceway at the entrance e, as shown in section in Fig. 5, and so that when the block, cap, and disk are moved together inwardly (as by pushing pressure at or near the groove h^3) the inclined plane of the head-plate will cause the compression of the packing to a desired or proper degree upon the entrance of the parts to the straight or pressure-maintaining portion of the raceway, as indicated in the sectional view Fig. 6, where the heat from the burner is applied to the adjacent surface of the top of the cap. If, then, a second block, disk, and cap be entered and forced along into the raceway, the first will be moved before it, as by contact of the rims of the blocks (or be separately pushed along, as by a forked rod applied at the groove) until said first cap will overlie the cooling-jets g, at which the escaping air, by prompt expansion, will afford a low temperature, and so on, it being understood that after passing the air-jets the finished closures and blocks drop freely from the raceway because of its vertically-enlarged exit. It should be also understood that in proportion to the speed at which the raceway is supplied with caps, &c., either the longitudinal areas of the heating and cooling appliances or their respective capacities should be varied, so that however rapid the movement of the caps may be the heating and the cooling capacities should be such as to surely and safely heat and then to effectually cool the heated parts and harden the fusible medium before release from pressure occurs, and as those capacities are controllable they may be gaged to the limits which experience in working would show to be needed with each lot of caps. Now, referring back to the second step, it will be seen that it terminates with the release of the cap, &c., from the fusing operation at the heater

and that if the raceway was long enough (and there were no air-jets) the caps and blocks could be moved along (as others entered) and so kept under pressure until sufficient time had elapsed for the prevailing temperature of an average factory to assist in cooling of the cap and disk and hardening the fused medium. It will, however, be obvious that with the variable temperature of a room, as well as of the variations in exterior normal temperature, there would be corresponding variations in time required for perfecting the operation and also that with the long raceway suggested a large number of press-blocks would be required. However slowly the hardening of the fused medium may be accomplished, if it be done under the controlling pressure indicated valuable results will accrue; but many of the important objects of my invention can only be secured by hardening the fusible medium by the exposure of the assembled heated parts under pressure to artificial cooling influences, and hence an appropriate clause of claim will be presented for securing that portion of my invention. The packing-disks necessarily become heated and being slow to absorb heat are equally slow in releasing it, and the disks are liable to be injured from undue heating. As heat can only be applied to the fusible material and the disk by way of the metal cap, it follows that radiation of heat in cooling the medium, the disk, and cap must be mainly backward through the metal. The compressed disk and the imposed press-block afford little or no path for the escape of heat in that direction, and if the disk be released from pressure while still hot the controlling effect of the binding medium could not be assured, and a hot disk in seeking to assert its natural resiliency after compression could not be so thoroughly under control as when the disk, cap, and the interposed medium are all well cooled under appropriate pressure.

Various artificial cooling influences may be employed without departure from my invention—as, for instance, a cooling-table containing a refrigerant, as the opposite of the electric heating-table hereinbefore referred to, or by inclosing a considerable portion of a raceway within a conduit jacketed for the circulation of a refrigerant or cooling medium; but the most convenient, reliable, and readily-controllable cooling influence known to me is afforded by the jets of compressed air. The objects sought by me by the employment of artificial means for cooling the assembled parts and hardening the fusible medium are to accelerate production; to secure practical uniformity in the finished product; a complete "fixing" or setting of the packing-disk in the form or condition induced by heat and pressure; to enable heat to be applied safely up to the last second of requirement, and then to end it abruptly, thus obviating liability of injury to the disk and of boiling, overheating, and ruining the fusible medium; to assure a prompt contraction of the metal cap (after expansion by heat) before the packing is cooled and the fusible medium hardened; to reduce the number of press-blocks or equivalent pressing factors to a minimum, and to render it possible for the second and third steps of the process (including also the assemblage of disks and caps) to be rapidly and perfectly executed by compact automatic mechanical organizations, because the heating and the cooling operations being each accurately controllable as to time each can be readily gaged for coöperation with mechanism which can be operated at any given speed consistent with the various requirements.

For indicating the status of my present invention as to novelty I will state that so far as my knowledge extends the nearest approaches thereto are to be found in disclosures made by me in my hereinbefore-mentioned Letters Patent No. 468,226, dated February 2, 1892. In my present operations the packing-disks are thicker than those indicated in said patent, as a precautionary measure of safety, and I employ therewith as a rule a paper collet as a suitable substitute reinforce for the thin fabric reinforce disclosed in my Letters Patent No. 468,259, the same having also been used by me as an effective form of the protecting-film described in said Patent No. 468,226, when said collet is charged with the fusible medium, as hereinbefore indicated. In said Patent No. 468,226 I also disclosed the use of the fusible protecting adhesive medium, such as shellac and Egyptian asphaltum, and also the compression of cork disks after application of heat for fusing said medium. Up to the time of making my present invention, however, the pressure has been promptly removed from the disks after they were compressed in the cap upon the shellac, and thereafter heated, and hence during the cooling of the cap and disk and the hardening of the shellac, even with thin disks, there was no such full control of the mass as would or could insure those desirable and valuable results in the finished product as are secured by maintaining the parts under pressure while heated and until they are cooled as in accordance with my present invention.

Having thus described my invention, I claim as new and desire to secure by Letters Patent—

1. In the manufacture of gas-tight bottle-closures composed in part of metal, the method or process which consists; first, in interposing a suitable fusible protecting and binding medium between the packing or sealing gasket and the coincident surfaces of the metal coöperating therewith; secondly, heating the metal, the gasket and the binding medium for properly fusing the latter, and in the meantime subjecting the whole to appropriate pressure; and thirdly, cooling the metal and avoiding injury to the gasket from undue heating

and hardening the fusible medium while maintaining said appropriate pressure, substantially as and for the purposes specified.

2. In the manufacture of semimetallic gas-tight bottle-closures, the method or process which consists: first, in interposing a suitable fusible medium between the packing or sealing gasket and the coincident surfaces of the metal coöperating therewith; secondly, heating the whole and properly fusing said medium, and in the meantime subjecting the whole to appropriate pressure; and thirdly, while still maintaining said pressure, promptly cooling the metal and avoiding injury to the gasket and hardening the fusible medium by artificial cooling influences, substantially as and for the purposes specified.

3. In the manufacture of semimetallic gas-tight bottle-closures, the method or process which consists: first, in interposing a suitable fusible medium between the packing or sealing gasket and the coincident surface of the metal coöperating therewith; secondly, heating the whole and properly fusing said medium, and in the meantime subjecting the whole to compression; and thirdly, cooling the metal and avoiding undue heating of the gasket and hardening the fusible medium while said compression is maintained, substantially as described.

In testimony whereof I have hereunto signed my name in the presence of two subscribing witnesses.

WILLIAM PAINTER.

PETITION.

The Honorable Commissioner of Patents:

Your petitioner, Albin H. Warth, a citizen of the United States, residing at Baltimore, in the ~~County~~ and State of Maryland, (whose Post-Office address is c/o Crown Cork & Seal Co., Baltimore, Md.) prays that Letters Patent of the United States be granted to him for the invention in a Process of Producing Closures

set forth in the annexed specification, and he hereby appoints Cleon J. Sawyer, James Q. Rice, James J. Kennedy and Philip B. Philipp (of the firm of Philipp, Sawyer, Rice & Kennedy, St. Paul Building, 220 Broadway, New York, P. O. Box 164, City Hall Station), his attorneys, with full power of substitution and revocation, to prosecute this application, to make alterations and amendments therein, to receive the Patent, and to transact all business in the Patent Office connected therewith.

Albin H. Warth

SPECIFICATION.

To all whom it may concern:

Be it known that I, Albin H. Warth, a citizen of the United States, residing at Baltimore, ~~County~~ of ~~and~~ State of Maryland, have invented certain new and useful improvements in a Process of Producing Closures fully described and represented in the following specification and the accompanying drawings forming a part of the same.

7.

This invention relates to a method of producing closures of the type in which a sealing disk has a metal foil facing.

Closures of the well known crown cork type comprise a metal shell having a skirt and a resilient sealing disk usually made of cork. For some uses, the sealing disks are given a facing of metal foil, e.g. tin foil, or aluminum foil. Ordinarily this facing is of smaller diameter than the cork disks and such crowns are known in the trade as spot center crowns.

These spot center crowns have been produced in various ways. According to one method a slot or groove is cut in the cork disk and the ~~tin foil~~ spot is given an inturned rim which is inserted in the slot. This method is objectionable because of its expense and because the ~~tin foil~~ spots are apt to drop out. According to another method the ~~tin foil~~ spots are pasted to the cork disks by a casein paste or a glue. In crowns so made the spots tend to loosen as the paste or glue is attacked by the packaged liquids. Furthermore, such method involves difficulties in handling and in applying the paste or glue. According to still another method the spots are secured by an underlying tissue of gutta percha or coated paper. In crowns so made, like objections are met with.

It is an object of the present invention to provide a method of producing spot center crowns such that the ~~metal foil~~ spots are easily and economically secured to the sealing disks and such that they are firmly secured and not liable to become loosened in use.

With these general objects in view the invention consists in the method which will be first described and then more particularly pointed out in the claims.

According to the method of the present invention, the metal foil, is coated with a substance that is devoid of tackiness when dry and has adhesive qualities when soft. In carrying out the method according to what is considered the best practice the adhesive substance is such that it can be applied cold, i.e. at room temperatures, and is waterproof or insoluble in cold water. While various materials may be used I have found a suitable adhesive in a solution of damar gum and rosin in mineral spirit or turpentine to which is added 5% or less of a vegetable oil such as soya bean or china-wood oil. The damar gum and rosin may be in the proportion of 35% to the whole. The adhesive may have a drier of lead resinate or the like in a proportion of 2% or less.

While the coating may be applied to the ~~metal foil~~ material in various ways, it is conveniently applied in fluid form and cold to a strip of foil from which the spots are to be cut. In this connection it is noted that the ~~metal foil~~ spots may be conveniently assembled by feeding a strip of ~~metal foil~~ material over successive crown corks and cutting out a ~~metal foil~~ disk which is deposited on a cork, such assembling machinery being known in the art.

After the coating is applied to the metal foil it is dried. While this may be effected by air drying at room temperatures it is more rapidly accomplished at a temperature of about 300° F. maintained for about 30 minutes. When dried the coating is devoid of tackiness so that the metal foil may be handled without difficulty or trouble. This is particularly advantageous when the metal foil is to be fed in strips because the application of the adhesive is carried out independently of the assembling steps. Moreover, the coating gives the thin metal foil more or less body which facilitates feeding and cutting.

After the coating is dry, the metal foil spots are assembled, coated side down, with the sealing disks. It

case the metal foil is fed in a strip, spots may be cut out and deposited on the sealing disk, as above set forth.

At the time of assembly the coating material is softened to render it adhesive and the assembled unit is subjected to pressure. In carrying out the invention according to what is now considered the best practice the coating will be softened by heat after the crown is assembled. This may be accomplished in any suitable manner, as by a heated plunger or a plunger and heated table. The heat softens the coating and renders it adhesive and the pressure serves to unite the metal foil spot to the cork.

The assembled unit is then cooled and the cooling may advantageously be coupled with pressure, for example, by a plunger. Cooling may be effected in any suitable manner, being carried out to the congealing point of the coating material.

It may be desirable to secure the metal foil spot in position, prior to the heat and pressure steps, sufficiently to prevent dislodgement of the spot during any interval between assembling and final sticking. This may be accomplished, for example, by preheating the assembled crown, to soften the coating, as soon as the metal foil spot is deposited. Or the coating may be softened by moistening slightly with a solvent, such as benzol. In either case the coating becomes tacky enough to hold the metal foil spot from getting out of position during ordinary massage through assembling apparatus.

The resulting crown has a firmly secured metal foil spot which is not liable to become loose in use owing to the fact that the adhesive substance is not soluble in liquids more commonly sealed by crown corks. Moreover, when the metal foil is assembled with the sealing disk it is already prepared for being stuck in place, the sticking being accomplished by the simple application of heat and pressure. The coating operation is a simple one and the coated metal foil is easily handled because the dry coating is not tacky.

1247

1491

I. c.

WHAT IS CLAIMED IS: (C"-cl. 1)

1. The method of producing closures of the type in which a sealing disk has a metal foil facing, which comprises coating metal foil with a substance which is adhesive when soft and substantially devoid of tackiness when dry, drying the coating, softening the coating, and pressing the coated metal foil against a sealing disk.

2. The method of producing closures of the type in which a sealing disk has a metal foil facing, which comprises coating metal foil with an adhesive substance, cutting a facing spot from the metal foil, assembling the coated spot with a sealing disk, and applying heat and pressure to the assembled unit.

3. The method of producing closures of the type in which a sealing disk has a metal foil facing, which comprises coating metal foil with a substance which is adhesive when soft and substantially devoid of tackiness when dry, drying the coating, cutting a facing spot from the coated metal foil, assembling the metal foil spot with a sealing disk, heating the assembled unit to soften the coating, and applying pressure to the assembled unit while so heated.

4. The method of producing closures of the type in which a sealing disk has a metal foil facing, which comprises coating metal foil with a substance which is adhesive when soft and substantially devoid of tackiness when dry, drying the coating, assembling the coated metal foil with a sealing disk, heating the assembled unit to soften the coating, and applying pressure to the assembled unit while so heated.

5. The method of producing closures of the type in which a sealing disk has a metal foil facing, which com-

prises coating metal foil with a liquid substance at room temperatures, which substance is adhesive when soft and substantially devoid of tackiness when dry, drying the coating, assembling the ~~coated metal~~ metal spot foil with a sealing disk, heating the assembled unit to soften the coating, and applying pressure to the assembled unit while so heated.

6. The method of producing closures of the type in which a sealing disk has a metal foil facing, which comprises coating metal foil with a substance which is adhesive when soft and substantially devoid of tackiness when dry, drying the coating, assembling the coated metal foil with a cork sealing disk, heating the assembled unit to soften the coating, applying pressure to the assembled unit while so heated, and cooling the softened adhesive, under pressure, to the congealing point thereof.

7. A substance for use in uniting metal foil spots to cork disks characterized by being substantially devoid of tackiness when dry and by adhesive qualities when soft and being rendered soft by heat.

8. A substance for use in uniting metal foil spots to cork disks characterized by being substantially devoid of tackiness when dry and by adhesive qualities when soft and being rendered soft by heat and being insoluble in cold water.

9. A substance for use in uniting metal foil spots to cork disks, comprising a solution of damar gum and rosin in mineral spirit having a small amount of a vegetable oil.

1249

MAIL DIVISION
JUN 27 29
U.S. PATENT OFFICE

U. S. PATENT OFFICE
JUN 28 1929
DIVISION 56

IN THE UNITED STATES PATENT OFFICE

In re application of
Albin H. Warth,
PROCESS OF PRODUCING CLOSURES,
Serial No. 159,743,
Filed Jan. 7, 1927.

Div. 56 - Room 311

New York, June 26, 1929.

Hon. Commissioner of Patents,
Washington, D. C.

S i r :

In response to Official action of Jan. 11, 1929, amendment is hereby made as follows:

Erase claims 1, 4 and 6.

In claim 5, at the end of line 5, insert: cutting a facing spot from the coated foil,

Same claim, line 6, for "coated metal foil" substitute - metal foil spot

R E M A R K S

By this amendment applicant has endeavored to reduce the number of claims. Reconsideration is requested as to the remaining claims.

Applicant has provided an efficient and beneficial method of producing spot center crowns, not disclosed or suggested in the references. In carrying out the invention, as defined by the claims, tin foil - either in strip or sheet form - is coated with a substance that is adhesive when soft and substantially devoid of tackiness when dry. The coating is dried, a "spot" is cut from the coated foil and assembled with a sealing disk. The assembled unit is then subjected to heat to soften the coating and to pressure to

1255
1499

With the method described, the adhesive may be applied cold, i.e. at room temperatures. By coating a sheet or strip of foil and then cutting out spots, the necessity of applying an adhesive to individual crowns during assembly is avoided. The coated strip or sheet can be handled in assembly machines without difficulty because the coating when dried is devoid of tackiness. Moreover, the coating gives the foil a certain amount of body which facilitates handling.

The Examiner states that any of the references discloses the use of an adhesive rendered soft by heat and applying under pressure. But applicant is not claiming anything so broad as that. None of the references discloses coating foil with a substance of the characteristics mentioned, drying the coating to render it non-tacky, cutting a spot from the coated foil and assembling by heat and pressure.

Allowance is requested.

Respectfully submitted,

Albin Horvath

GPO 11—3223

February 4, 1930

Applicant: Albin H. Werth

Philipp, Sawyer, Rice & Kennedy, 220 Broadway, New York, N.Y.

Ser. No. 159,743
Filed Jan. 7, 1927
For Process of Producing Closures

FEB 4 1930

Responsive to amendment filed June 27, 1929.

Claims 2, 3 and 5 are again rejected on the reference to Marsa who fully discloses applicant's process. Marsa discloses the application of adhesive in spots to a metallic sheet, cutting 'spots' from the sheet and then drying the adhesive. See page 1, lines 83-89. A sealing disk is then applied to the coated spot, heat is applied to fuse the cement (page 1, lines 100-105) and then pressure is applied.

Claims 2 reads directly on this reference and claims 3 and 5 differ only in sequence of the drying step. The applicant dries first, then cuts, whereas, the patentee cuts and dries. This mere change in sequence is a non-patentable variation and devoid of invention.

As an issue has been reached, this rejection is now made final.

Examiner.

July 24, 1930

In re: Application of
Albin H. Warth
Baltimore, Md
For: Process of Producing
Closures
Filed: Jan. 7, 1927
Serial No. 159,743

Before the
Board of Appeals
On Appeal

EXAMINER'S STATEMENT

Applicant has appealed from a final rejection of claims 2, 3 and 5, all in paper No. 1.

The reference relied upon is:

Masa 1,603,786 Oct. 19, 1926

The invention claimed consists of a method of producing sealing disks for bottle caps in which metal foil is coated with a cement which is sticky when soft or wet and devoid of tackiness when dry, drying this coating, cutting a disk from the metal foil, assembling the metal foil spot with a sealing disk, heating the unit so as to soften the cement and applying pressure to the unit while so heated.

This method has the advantage of providing a facing spot which is free from tackiness and, therefore, easy to handle. The method, however, is completely anticipated by Masa. This patent coats a metal sheet with a fusible cementing material and then subjects the sheet to heat in an oven so as to evaporate the solvent material of the cement. Disks suitable for crown cork

1259

1503

Ser. No. 159,743. Sheet #2.

caps are then cut from this metal sheet, bent into the shape of a crown cap, a sealing disk of cork inserted andthe unit heated in order to fuse the cementing material, the metal and the sealing disk then being united under pressure. The patentee states that the cement may be heated either before ot after assembling the unit andthe steps of the process are, therefore, substantially the same.

While the patentee applies cement to the crown cap itself and applicant applies cement to a facing disk to be inserted in a crown cap this is not believed to be a patentable difference since the result is the same and the patentees process could just as readily be applied to the production of the closures shown by applicant, the steps being identicaland the materials substantially the same

Respectfully submitted.

Paper No.

DEPARTMENT OF COMMERCE
UNITED STATES PATENT OFFICE
WASHINGTON

November 17, 1930

Sir:

The case of Albin H. Barth

Serial No. 159,745, will be heard by the Board of ~~Interference~~

Appeals on the 23rd day of December, 1930

The hearings will commence at ~~9:30 A.M.~~ 1:30 P.M. and as soon as the argument in one case is concluded the succeeding case will be taken up.

If any party, or his attorney, shall not appear when the case is called, his right to an oral hearing will be regarded as waived.

The time allowed for arguments is as follows:

Ex parte cases, thirty minutes;
Inter partes appeals: Interlocutory and final hearings when no testimony has been taken, thirty minutes each side; final hearing when testimony has been taken, one hour each side.

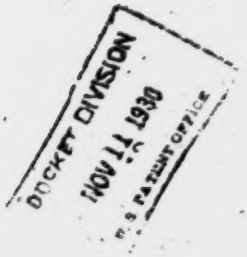
By special leave, obtained before the argument is commenced, the time may be extended.

The appellant shall have the right to open and conclude in inter partes cases, and in such cases a full and fair opening must be made.

Briefs in inter partes appeals must be filed in accordance with the provisions of Rules 144 and 163.

Respectfully,

Thomas E. Robertson



Commissioner of Patents.

Div 56 - #13
Now on appeal to Board of Appeals

IN THE UNITED STATES PATENT OFFICE.

Inventor: Albin H. Warth,
Invention: Process of Producing Closures,
Serial No. 159,743,
Filed January 7, 1927.

POWER OF ATTORNEY.

Hon. Commissioner of Patents,
Washington, D. C.

Sir:-

The Crown Cork & Seal Company, Inc., assignee of the entire interest in the above entitled application, hereby appoints, as its attorneys, with the usual powers, Cushman, Bryant & Darby, a firm composed of Arlon V. Cushman, Arthur L. Bryant and John J. Darby, (Reg. No. 7196), Washington Loan & Trust Building, Washington, D. C.

All existing powers are hereby revoked.

Appeal No. 135 Paper No. 14

IN THE UNITED STATES PATENT OFFICE.

Albin H. Warth,
PROCESS OF PRODUCING CLOSURES,
Filed January 7, 1927,
Serial No. 159,743.

U.S. PATENT OFFICE
DIVISION 56

BEFORE THE BOARD OF APPEALS.

In view of the recent conferences with the Primary Examiner, from whom this case was appealed (Div. 56), appellant has submitted an amendment which is thought to place the case in condition for allowance.

This amendment bears the endorsement of the Examiner to the effect that it places the case, in his opinion, in condition for allowance. The single claim presented in the amendment has also been approved by the Primary Examiner in Division 15.

BOARD OF APPEALS
U.S. PATENT OFFICE

In view of the Examiner's endorsement of the proposed amendment, appellant consents to and requests (1) dismissal of the appeal, and (2) a recommendation by the Board that the Examiner enter the attached amendment and allow the application.

Respectfully,
Albin H. Warth.

By [signature]
Attorneys.

U. S. PATENT OFFICE
DEC 3 1930

Hon. Commissioner of Patents,
Washington, D. C.

Sir:

We hereby authorize and request entry of the following amendments in the above entitled application.

IN THE SPECIFICATION

Page 1

Line 3 after the period insert --This type of closure is characterized by the provision, upon the interior cushion or sealing disc, of a facing or spot having a surface which protects the cushion material from the liquids and gases.--

Line 7 before "facing" insert --non-absorbent, gas impervious and acid resistant--.

Line 8 after the period insert --Aluminum foil is characterized by the fact that it is substantially non-absorbent and gas impervious, and for this reason the same and other materials having similar characteristics are used to form facing discs or spots upon the cushion material of crown caps.--

Line 13 cancel "tin foil".

Line 15 cancel "tin foil".

Line 17 cancel "tin foil".

Line 24 after the period insert the following:

For example, one difficulty in applying discs made from separate strips, such as gas and acid resistant material and the adhesive tissue strips, has arisen from the neces sity for feeding the two strips to the punching and assembly machine. There is not only difficulty in feeding the strips, but in cutting the separate tissue strip with a clean, sharp edge so as to insure the binding stratum of adhesive being coextensive in area with the disc of liquid resistant material. As will be understood, the adhesive stratum is intended to act not only as a cement, but also as a waterproof, non-absorbent, gas impervious C-3 medium for avoiding the possibility of the contents of a bottle getting between the facing disc and the material of the cap, either the metal shell itself or a cushion disc of cork or composition cork.

Furthermore, when using superimposed strips of the facing material and of adhesive tissue, it was essential, to bond the adhesive tissue to both the material of the cushion disc in the cap and the facing material.

In preparing the rolls of facing material and adhesive tissue, the practice usually followed was to form a roll of the tissue in strips of the desired width, and to unwind this roll and a roll of the facing material while feeding the two strips one over the other into the disc forming and assembling machine. This is a troublesome and expensive operation, because of the frequent breakage of the adhesive tissue and the necessity for using fairly heavy tissue to minimize this tendency. This is due partly to the fact that the facing material was substantially non-elastic, while the adhesive tissue possessed a certain degree of elasticity, thus introducing a factor of difficulty in securing a uniform paying of both the facing strip and the gutta percha tissue strip.

It is desirable, in the use of facing disks of the character above referred to, that the adhesive stratum be as thin as possible, and yet be continuous throughout the entire area of the facing disk, and particularly that it be uninterrupted about the edge of this disk, since at this point the disk should be firmly bonded so as to effectively seal the joint about the edge of the facing disk. When cutting and applying the disks of material and adhesive, there is no means of ascertaining whether the desired conditions are present in the completed cap. Consequently, there is always likelihood of imperfectly faced caps being produced.

With the above conditions in mind, I have provided material, in strip form, for facing bottle caps, in which one surface of the strip is provided with a firmly adherent, continuous thin facing of adhesive, thus avoiding all necessity for assembling strips of facing material and of adhesive tissue preparatory to their use in the bottle cap facing machine, and all of the disadvantages growing out of this practice.

In the strip material of my invention, a very thin stratum of adhesive is evenly distributed upon one face of a strip of facing material. The adhesive is not only firmly bonded to this material, but has a smooth surface finish of sufficient thickness to form the desired firm bond between a disk cut from the strip and the material of the cap to which such disk is cemented.

Furthermore, adhesive tissue must be of a thickness to have sufficient inherent strength to permit of its being stripped from a roll in a mill for working same, and to admit of its being cut to the desired width and to be handled in the winding and the disk applying machines, and during the process of its production it has more or less of a longitudinally extending grain, as distinguished from its normal granular formation.

C 3

In the application o heat, when bonding the facing material to the cap, when utilizing adhesive tissue, a tendency of the adhesive is to break up into slightly isolated, small globules, thus interrupting the continuity of the bonding stratum. Whether this is due to irregularities in the surface of the facing strip, or to a shrinkage of the adhesive tissue when fused, I have been unable to determine. In the strip of my invention, however, the adhesive is thoroughly distributed throughout one face of the facing material, and the above conditions do not develop in the subsequent handling of the strips.

Line 27 cancel "metal foil".

Page 2

Line 2 before "metal" insert --strip material having a surface which is substantially non-absorbent and gas impervious, such as--

Same line (2) after "foil" insert a comma.

Line 6 before "insoluble" insert --waterproof or--

Line 13 after the period insert --This adhesive is waterproof and is not weakened by gases or acids, such

as are present in the bottle contents with which crown caps are usually employed.

Line 15 cancel "metal foil" and substitute --material--

Line 17 after the period insert —So far as the method of producing the strip is concerned, it is such that the effective distribution of the adhesive throughout the entire area of the facing material is assured, and this condition cannot be distrubed as a result of the cutting of discs from this material when in strip form. Furthermore, the adhesive surface may be thoroughly inspected while producing the strip material, so that any imperfect product may be discarded before it reaches the disc applying machine.—

Line 17 cancel "metal foil".

Line 19 cancel "metal foil" and substitute --material--

Line 20 cancel "metal foil".

Line 32 after the period insert —Since the adhesive is applied directly to the surface of the facing or spot material and firmly bonded thereto, there is no likelihood of difficulties arising as a result of separation of the adhesive from the facing strip during the spot forming operation, either as a result of poor adherence or from suction or otherwise, such as frequently occurs when using superimposed strips of facing material and of adhesive tissue. Moreover, in handling this material the adhesive stratum is incapable of stretch or distortion relative to the spot strip as frequently occurs in the handling of separate strips of adhesive tissue and facing material where any stretch or distortion of the adhesive stratum results in a defective cap and when the stretch is extreme, tearing of the adhesive

tissue makes necessary the stoppage of the cap machine until the strip can be repaired.

Page 3

Line 8 after the period insert:

In cutting discs from this improved laminated strip having an adhesive stratum bonded thereto, there is no tendency toward mutilation of the adhesive layer by reason of possible drag of the cutting dies, and each disc, as delivered from the die to within a cap, will present a continuous uninterrupted adhesive surface upon the disc so as to insure, by the subsequent application of heat and pressure, a bond between the disc and the cap cushion layer coextensive in area with the disc.

This possibility of securing a clean cut by the dies for forming the discs, both as to the non-absorptive and gas impervious, and as to the adhesive stratum, insures an effective bond entirely about the edge of the spot or disc, thereby presenting a continuous barrier of non-absorptive and gas impervious material at the space between the disc and the cap which will effectively prevent the seepage of gas or fluid in a bottle between the disc and the portion of the cap to which it is applied.

Although the adhesive facing is sufficiently thick to provide an adhesive stratum or layer, it is sufficiently thin to avoid any tendency toward the expression during the application of pressure of any of the adhesive from between the facing material and the portion of the cap to which it is applied.

Line 11 after the paragraph insert the following:

Referring to the accompanying drawings, there is shown suitable mechanism for coating the strip and for

cutting discs therefrom and adhesively uniting the disc to caps at the time of the assembly of the discs with the caps. In the drawings,

Figure 1 is a diagrammatical view showing the coating of the strip.

Figure 2 is a longitudinal sectional view of a fragment of the strip.

Figure 3 is a side elevational view partly in section showing one step in the assembly operation.

Figure 4 is a view similar to Figure 3 showing the spot as it is cut and adhesively united to the cap at the time of assembly.

Figure 5 is an interior face view of the completed cap, and

Figure 6 is a cross sectional view of the cap shown in Figure 5.

The strip of facing material should have the characteristic of aluminum foil. That is to say, it should present one surface which is non-absorbent and gas impervious. This strip may be fed from a reel 10 to a reel 11, suitably separated so that the adhesive coating may be applied and hardened between the time any portion of the strip leaves the reel 10 and is wound upon the reel 11. For the purpose of applying the adhesive, the same may be maintained in a trough 12, positioned beneath an adhesive applying roll 13, between which and a roll 14, the strip passes, so that as the rolls are rotated the adhesive is applied to the undersurface thereof. As will be understood, the adhesive hardens between the time it is applied and the winding of the laminated strip upon the reel 11.

The completed spot material or liner is illustrated in

Figure 2, and comprises the layer 15 of non-absorbent and gas impervious material, such as aluminum foil having on one surface the coating 16 of adhesive, which is preferably of the character hereinbefore described. This adhesive is waterproof or liquid resistant, and will be normally hard, i. e. non-tacky, at room temperature so that the material may be conveniently handled in strip form, but quickly softens under the application of heat, becoming tacky, so that upon the application of pressure, the laminated disc will be adhesively retained in the cap. The preferred method of applying the material to the cap is to utilize, at the time of assembly, both heat and pressure to unite the spot to the cork or cushion material insert or facing of the cap.

In Figures 3 and 4, there is shown a suitable mechanism for applying the disc and adhesively uniting it to the cork insert at the time the strip is punched from the disc and assembled with the cap.

The cap 17 is of the conventional crown type having an interior facing 18 of cushion material, such as composition cork retained in the cap as by an adhesive layer 17'; the cushion disc and adhesive may be applied to the cap in any suitable manner, for example as described in the patent to Marsa, No. 1,603,786, granted Oct. 19, 1926. The caps, with the cushion discs inserted therein, may be positioned beneath the cutting dies 19, 20, by means of a traveling bed 21 having suitable sockets for receiving the cap so as to position the same accurately beneath the cutting dies. The strip material for forming the spot is fed beneath the die 20 with the adhesive coating 16 facing the cap, and when the die descends it will cut from the strip, which is fed by any suitable means (not shown), a spot or facing 22

of the character illustrated in Figures 5 and 6. The spot or disc is preferably of smaller diameter than the cap facing so as to form a substantially centrally disposed spot which leaves around its edge an exposed portion of the cushion material adapted to engage the edge of a bottle neck, the spot being of sufficient size to close the bottle mouth and prevent contact of the contents with the cushion material.

As will be observed (Figures 3 and 4) as the punch 20 deseends, it cuts from the strip a spot of the size shown in Figure 5, and continued downward movement presses this disc upon the cushion layer 18.

The punch 20 may be maintained at an elevated temperature, as by means of a burner 26, and the temperature should be sufficient to fuse or soften the adhesive coating and make it tacky so that, at the time the disc is assembled with the cap, the heat and pressure will cause the disc to be adhesively united to the surface of the cushion material with sufficient permanency to insure that the position will be retained and avoid likelihood of displacement of the disc thereafter.

Page 3

Line 12 cancel "cooled" and substitute --permitted to cool--

Line 17 cancel the paragraph beginning "It may be desirable".

Page 4

After the last line insert the following:

A cap made in accordance with this method possesses the advantage of a substantially uniform and complete distribution of the adhesive layer throughout each spot or facing disc. The method has the advantage of eliminating the

1274

1518

labor of associating a separate adhesive strip and a strip of facing material, and the further advantage of enabling higher speeds to be maintained in the facing spot applying machine. The elimination of the danger of breakage of a separate adhesive tissue strip avoids the frequent stoppage of the machine, which was unavoidable due to the handling of the somewhat fragile and elastic adhesive tissue.

IN THE CLAIMS:

Cancel the claims and substitute:

1275

1519

hwd

07a

The improved method of manufacturing caps of the type having an interior disc of cushion material provided on its exposed face with a center spot, which comprises providing spot material in strip form having one surface formed of an exposed continuous coating of water resistant adhesive which is normally hard at room temperature but becomes tacky upon the application of heat and having another surface to be exposed to the contents of a capped container, cutting from said strip a facing spot having one surface completely coated with said adhesive with a cap disposed beneath the portion of the strip from which the spot is cut, whereby the cutting operation positions the spot upon the cushion material with the coating between the spot and the cushion material, and upon assembly applying simultaneously to the spot pressure and sufficient heat to render the adhesive tacky, thereby causing the spot to adhere to the cushion material, and thereafter permitting the adhesive to cool and harden.

~~claim~~ D'

D) Please enter the accompanying sheet of drawings.

D'-6.2

REMARKS

It is believed that the foregoing amendments place this case in condition for allowance, and that the Examiner will feel warranted in recommending to the Board of Appeals, that the amendment be entered and the new claims allowed.

To the best of my knowledge and belief, the claim submitted by this amendment is patentable. The balance of the amendment can be entered and the case passed then be passed for issue.

J.J. Porter
Examiner
Dec 56.

With respect to the delay in presenting this amendment, a recent conference between present attorneys and the applicant made it apparent that the real problem which applicant has solved and the definite advance he has made over the prior art, are not set forth in the specification

with sufficient distinctness to cause the Examiner to appreciate the precise problem the applicant has solved and the importance of his contribution to the art. Immediately upon discovering this fact, applicant's attorneys took steps to obtain a conference with the Examiner and to present to him the additional information which, as now embodied in the specification, is thought to justify the allowance of protection. It is thought that these conclusions are borne out by the interview kindly granted the applicant and his counsel, and that in view of these facts the delay in presenting the amendment and claims may be properly excused. If the Examiner desires an affidavit explaining the reason for the delay in presenting claims of the character now submitted, it will be furnished.

The Examiner's attention is particularly directed to the additional matter inserted in the specification. This matter simply explains the relation of the present invention to the prior art and defines the characteristics of the material involved in the use of the method which make the method a very valuable advance over former practices.

The applicant does not claim to be the first to have used metallic foil; this material is simply one of numerous materials which have been used for years in the spotting or facing of caps. These cap facings or spots are employed in order to afford a non-absorbent, gas impervious and acid resistant surfacing for the cushion material which is used in crown caps. As the Examiner will, of course, appreciate, other materials have been used, such as paper suitably finished to impart these characteristics to the same.

At the time the applicant made the present invention, it was customary to "spot" by feeding the acid and gas resistant material in strip form, and also the adhesive tissue in strip form, and to simultaneously punch from the strips discs of the acid resistant material and of the adhesive tissue. Another practice was to deposit on the cushion material of the cap the cement or liquid adhesive, and then to apply the disc of acid resistant material. The use of this liquid made the process slow in view of the difficulties in applying the glue or paste. Moreover, the use of a separate strip of adhesive in tissue form was objectionable for various reasons, which are now fully explained in the specification. Briefly stated, these objections were:

FIRST - it was difficult to handle the adhesive in tissue form and breakage of the same made necessary the stopping of the cap machine.

SECOND - stretching or distortion of the tissue adhesive made it difficult to obtain exact registry of the tissue disc and acid-resistant material disc when the two were applied to a cap.

THIRD - due to drag in the cutting dies, it was not always possible to obtain exactly corresponding sizes of tissue and material discs, with the result that the entire bottom surface of the material disc was not always backed with adhesive and the material disc was not always united to the cushion throughout its entire edge.

FOURTH - the necessary thickness of the adhesive tissue resulted in expression of the same from beneath the facing when pressure is applied to the spot.

FIFTH - the handling of two strips of material retarded operation of the cap assembling machine.

SIXTH - the necessary thickness of the adhesive tissue made it difficult to obtain a firm bonding of the tissue and facing material throughout the face of the disc.

SEVENTH - after the punching operation the separate discs moved out of registration and resulted in a large proportion of deffective caps.

These and other objections to the previously used processes have been overcome by the applicant. His invention involved, as a primary concept, the elimination of the use of separate strips in the cap assembly operation. As a secondary concept, it involved the provision of a unitary multi-layer strip with the layers bonded, one surface of this strip being a waterproof adhesive which will soften under the application of heat and pressure, and the other surface being acid resistant, gas impervious and non-absorbent. It has frequently been pointed out by the Courts that invention often consists in discovering what is the difficulty with existing structures or methods, and that this constitutes invention, although the means for overcoming these objections are comparatively simple. For example, Judge Hough said in the case of Kurtz et al, v. Belle Hat Lining Co., Inc., (C. C. A. 2nd Cir.) 280 Fed. 277 (at 281):

> "Patentability has often been found 'in discovering what is the difficulty with an existing structure' and correcting the same, even though 'the means' are old and their mere 'adaptation to the new purposes involves no patentable novelty.' Miehle, etc., Co. v. Whitlock, 223 Fed. 647, 650, 139 C. C. A. 201. Hindsight, or wisdom after the fact, has always been looked upon with disfavor; e. g. Parlee Co. v. Brown, 121 Fed. 547, 550, 57 C. C. A. 609."

The same Circuit Court of Appeals in the earlier case of Miehle Printing Press & Mfg. Co. v. Whitlock Printing Press Co., 223 F. R. 647, said:

> "Patentable novelty is sometimes found in discovering what is the difficulty with an existing structure and what change in

> its elements will correct the difficulty, even though the means for introducing that element into the combination are old and their adaptation to the new apparatus involves no patentable novelty".

In these decisions the Courts simply followed other decisions to the same effect, such as Patents Selling v. Dunn 204 Fed. 99; General Electric v. Hartman 187 Fed. 131; General Electric Co. v. Sangamo Electric Company (C. C. A. 7th) 174 Fed. 246. In the last case, the Court pointed out that there are two steps involved in an inventive act, namely (a) discerning in existing machines or processes some deficiency, and (b) pointing out the means to overcome the same. The Court said this in the following language:

> "Invention, in the nature of improvements, is the double mental act of discerning in existing machines, processes, or articles, some deficiency and pointing out the means of overcoming it."

The applicant's invention, from the standpoint of conception, consisted in three steps. First, he perceived that the former practices of using (a) paste or glue, or (b) a separate strip of adhesive tissue, were cumbersome and objectionable. He saw the objections and set out to overcome them. The second step in his invention was to supply the medium and method by which these objections might be eliminated. In connection with the second step, he supplied a material of laminated character having (a) one exposed surface which is acid resistant and gas impervious, and (b) another exposed surface with a thin coating of waterproof adhesive which softens under the application of heat, but is normally hard, so that the material may be conveniently handled. Thirdly, he went a step further and provided a complete method which involves the use of this material in such a way that caps might be more economically

produced and without the defects of caps produced according to the earlier methods. The applicant's method has numerous advantages, including the following:

1. The cost of product of spot crowns is very materially decreased; in fact this invention alone was the main factor in reducing the cost of production of spot crowns sufficiently to make possible commercial production.

2. There is but a single strip to handle, instead of the two separate strips of the former method.

3. There is no need of applying paste or glue to the cushion material of each cap.

4. The simultaneous cutting of the adhesive and material discs from a single strip insures that the adhesive is coextensive in area with the material with the result that there is no possibility of gas or moisture entering between the spot material and the cushion layer around the edges of the spot.

5. The thinness of the adhesive layer avoids expressi the adhesive when pressure is applied to the spot.

6. There is no tendency for distortion or stretching of the adhesive layer relative to the material strip.

7. There is no possibility of breakage of a fragile adhesive tissue which results in stoppage of the machine.

8. It is possible to inspect the facing material as it is fed into the assembly machine to insure that the entire surface is coated with adhesive, which cannot be done when the separate strips are fed or when paste or glue is first applied to the cushion material. In other words, imperfectly faced caps are virtually eliminated. There is absolute registration of the edges of the material disc and adhesive disc which is difficult to obtain in the manufacture from separate strips.

9. The discs in united form may be fed into the cap in absolute registry and assembled by the cutting punch, due to the bonded relation of the two layers.

10. The heat and pressure necessary for uniting the facing to the cap may be applied substantially simultaneously with the punching and assembly operations without waiting for inspection, since there is no danger of the adhesive and material discs moving out of registry with one another; this permits an operation in which the punch used to cut the discs may also be employed to apply the pressure.

These and other advantages of applicant's invention

make the same, from a practical standpoint, a radical advance in the art. The Examiner will appreciate this from the fact that this method has been adopted by the Crown Cork & Seal Company, in lieu of formerly used methods of the nature disclosed in the references cited. This Company, as the Examiner is probably aware, is the largest manufacturer in the world of crown caps.

THE PRIOR ART.

In view of the amplified description of the invention now embodied in the specification, the Examiner will undoubtedly appreciate that the disclosure in the patent to Marsa (1,603,786) has nothing whatsoever to do with this invention. The patentee is dealing with the formation of the cap and the application of the cushion layer thereto. The amended specification points out that this step takes place before the application of the facing spot, and that in the manufacture of the cap with which applicant's method is employed, the Marsa method may also be utilized. But the method described in the patent applies to an altogether different step in the manufacture of the cap. The Examiner's attention is called to the fact that applicant's assignee controls the Marsa patent, since the assignee of that patent, New Process Cork Company has been consolidated with the assignee of the present case.

The Marsa patent is the only one of the references of record which has in any way been advanced by the Examiner as pertinent to applicant's disclosure, and, therefore, it seems unnecessary to discuss the other prior art in detail. McManus (1,213,926) does not show a strip having an exposed adhesive surface. It would be impossible to practice applicant's method with this material.

The patent to Okie (1,565,097) obviously has no bearing upon the invention, since it relates to an adhesive composition.

The patents to Alberti (1,854,711) and Koch (1,858,156) contain no suggestion whatsoever of a method at all similar to that claimed by the applicant.

The French patent (557,791) shows a method of manufacturing a laminated disc in which an absorbent or porous layer 2 is united to a moisture resistant layer 8 by means of glue. The exposed layer 8 is not an adhesive layer. It is a moisture resistant layer, and may be applied as indicated at B in Figure 3 to only one side of the disc, or to both sides as shown in Figure 7. This moisture resistant layer is rubber treated with sulphur, and hence the construction has nothing whatsoever in common with either the material employed by applicant or the method of manufacture which applicant claims.

In addition to the foregoing art of record, the Examiner's additional search has recently developed certain references which it is thought should be made of record, and to these references we will refer briefly.

The patent to Alberti (1,941,300) does not show the method claimed, since the adhesive is applied to the cushion disc before the application of the disc.

The patent to Anderson (1,982,516) is from a non-analogous and unrelated art; it has nothing to do with cap manufacture or the application of spots to cushion material. The material employed and to which the coating is applied is not of the character which would resist the action of liquid and, therefore, is not spot material. Moreover, there is nothing in this patent suggestive of applying the method claimed to the art of cap manufacture.

Another distinction of importance is the fact that the adhesive employed is not water resistant, and this is of great importance, as pointed out in the specification and claims.

The patent to Burgard (835,176) discloses a machine for applyings tags or labels, and although an adhesive is applied to the strip material used, there is no suggestion that the strip material is of a nature which will resist the action of liquids or, in other words, constitute spot material. As a matter of fact, it is a material "capable of being marked or written upon " (spec. p. 5, l. 42) and, therefore, is gas penetrable and is not impervious to liquid.

The patent to Landfear (303,391) does not anticipate the claims for the same reasons as the other references. It shows a machine for applying discs to the ends of spools and obviously the material employed is not spot material, i. e. of a character adapted to protect the cushion of a cap. Furthermore, the adhesive is not water resistant.

DEC - 2 1930
MAILED

Appeal No. 135 MCV

IN THE UNITED STATES PATENT OFFICE

BEFORE THE BOARD OF APPEALS

Ex parte Albin H. Warth

Application for Patent filed January 7, 1927, Serial No. 159,743. Process of Producing Closures.

Messrs. Cushman, Bryant & Darby for applicant.

In view of the examiner's written endorsement that a proposed substitute claim is in his opinion patentable and that the accompanying amendment, filed November 25, 1930, would place the case in condition for allowance, the appeal is dismissed and the case remanded to the examiner for consideration of the amendment and for such action as he deems proper.

APPLICATION DIV. DEC 11 30 PATENT OFFICE

U. S. PATENT OFFICE
DEC 11 1930
DIVISION 14

- - -

Hon. Commissioner of Patents,
Washington, D. C.

Sir:

We hereby authorize and request entry of the following amendment in the above entitled application.

IN THE CLAIM

Apply the numeral "10" to the claim of record, and add the following claim:

10. The improved method of manufacturing caps of the type having an interior disc of cushion material provided on its exposed face with a center spot, which comprises providing metal foil spot material in strip form having one surface formed of an exposed continuous coating of water resistant adhesive which is normally hard at room temperature but becomes tacky upon the application of heat and having another surface to be exposed to the contents of a capped container, cutting from said metal foil strip a facing spot having one surface completely coated with said adhesive with a cap disposed beneath the portion of the strip from which the spot is cut, whereby the cutting operation positions the spot upon the cushion material with the coating between the spot and the cushion material, and upon assembly applying simultaneously to the spot pressure and sufficient heat to render the adhesive tacky, thereby causing the spot to adhere to the cushion material, and thereafter permitting the adhesive to cool and harden.

(sig.)

1287.

1531

_R_E_M_A_R_K_S_

The foregoing claim contains all of the limitations of the claim allowed, but is somewhat more specific, in that it is limited to the use of metal foil spot material and the production of a metal foil spot. In other words, this claim is limited to a production of one species of the center spot type of cap. In view of the fact that the claim is in no sense broader of the allowed claim, but is obviously more specific, it is thought that it may be entered without further search.

Respectfully,

Cushman Darby & Cushman
Attorneys.

WASHINGTON

December 11, 1930

Albin H. Warth, Assor. etc.

Your APPLICATION for a patent for an IMPROVEMENT in

PROCESS OF PRODUCING CLOSURES

filed Jan. 7, 1927 has been examined and ALLOWED with 2 claims.

The final fee, TWENTY-FIVE DOLLARS, WITH $1 ADDITIONAL FOR EACH CLAIM ALLOWED IN EXCESS OF 20, must be paid not later than SIX MONTHS from the date of this present notice of allowance. If the final fee be not paid within that period, the patent will be withheld, but the application may be renewed within one year after the date of the original notice with a renewal fee of $25 and $1 additional for each claim in excess of 20.

The office delivers patents upon the day of their date, on which date their term begins to run. The preparation of the patent for final signing and sealing will require about four weeks, and such work will not be begun until after payment of the necessary final fee.

When the final fee is paid, there should also be sent, DISTINCTLY AND PLAINLY WRITTEN, the name of the INVENTOR, TITLE OF THE INVENTION, AND SERIAL NUMBER AS ABOVE GIVEN, DATE OF ALLOWANCE (which is the date of this circular), DATE OF FILING, and, if assigned, the NAMES OF THE ASSIGNEES.

If it is desired to have the patent issue to an ASSIGNEE OR ASSIGNEES, an assignment containing a REQUEST to that effect, together with the FEE for recording the same, must be filed in this office on or before the date of payment of the final fee.

After issue of the patent, uncertified copies of the drawings and specifications may be purchased at the price of TEN CENTS EACH. The money should accompany the order. Postage stamps will not be received.

The final fee will NOT be received from other than the applicant, his assignee or attorney, or a party in interest as shown by the records of the Patent Office.

NOTICE.—WHEN THE NUMBER OF CLAIMS ALLOWED IS IN EXCESS OF 20, NO SUM LESS THAN $25 PLUS $1 ADDITIONAL FOR EACH CLAIM IN EXCESS OF TWENTY CAN BE ACCEPTED AS THE FINAL FEE.

Respectfully,

Thomas E. Robertson
Commissioner of Patents.

UNITED STATES PATENT OFFICE

ALBIN H. WARTH, OF BALTIMORE, MARYLAND, ASSIGNOR, BY MESNE ASSIGNMENTS, TO CROWN CORK & SEAL COMPANY, INC., OF NEW YORK, N. Y., A CORPORATION OF NEW YORK

PROCESS OF PRODUCING CLOSURES

REISSUED

Application filed January 7, 1927. Serial No. 159,743.

This invention relates to a method of producing closures of the type in which a sealing disk has a metal foil facing. This type of closure is characterized by the provision, upon the interior cushion or sealing disc, of a facing or spot having a surface which protects the cushion material from the liquids and gases.

Closures of the well known crown cork type comprise a metal shell having a skirt and a resilient sealing disk usually made of cork. For some uses, the sealing disks are given a non-absorbent, gas impervious and acid resistant facing of metal foil, e. g. tin foil, or aluminum foil. Aluminum foil is characterized by the fact that it is substantially non-absorbent and gas impervious, and for this reason the same and other materials having similar characteristics are used to form facing disc or spots upon the cushion material of crown caps. Ordinarily this facing is of smaller diameter than the cork disks and such crowns are known in the trade as spot center crowns.

These spot center crowns have been produced in various ways. According to one method a slot or groove is cut in the cork disk and the spot is given an inturned rim which is inserted in the slot. This method is objectionable because of its expense and because the spots are apt to drop out. According to another method the spots are pasted to the cork disks by a casein paste or a glue. In crowns so made the spots tend to loosen as the paste or glue is attacked by the packaged liquids. Furthermore, such method involves difficulties in handling and in applying the paste or glue. According to still another method the spots are secured by an underlying tissue of gutta percha or coated paper. In crowns so made, like objections are met with. For example, one difficulty in applying discs made from separate strips, such as gas and acid resistant material and the adhesive tissue strips, has arisen from the necessity for feeding the two strips to the punching and assembly machine. There is not only difficulty in feeding the strips, but in cutting the separate tissue strip with a clean, sharp edge so as to insure the binding stratum of adhesive being coextensive in area with the disc of liquid resistant material. As will be understood, the adhesive stratum is intended to act not only as a cement, but also as a waterproof, non-absorbent, gas impervious medium for avoiding the possibility of the contents of a bottle getting between the facing disc and the material of the cap, either the metal shelf itself or a cushion disc of cork or composition cork.

Furthermore, when using superimposed strips of the facing material and of adhesive tissue, it was essential, to bond the adhesive tissue to both the material of the cushion disc in the cap and the facing material.

In preparing the rolls of facing material and adhesive tissue, the practice usually followed was to form a roll of the tissue in strips of the desired width, and to unwind this roll and a roll of the facing material while feeding the two strips one over the other into the disc forming and assembling machine. This is a troublesome and expensive operation, because of the frequent breakage of the adhesive tissue and the necessity for using fairly heavy tissue to minimize this tendency. This is due partly to the fact that the facing material was substantially non-elastic, while the adhesive tissue possessed a certain degree of elasticity, thus introducing a factor of difficulty in securing a uniform paying of both the facing strip and the gutta percha tissue strip.

It is desirable, in the use of facing disks of the character above referred to, that the adhesive stratum be as thin as possible, and yet be continuous throughout the entire area of the facing disk, and particularly that it be uninterrupted about the edge of this disk, since at this point the disk should be firmly bonded so as to effectively seal the joint about the edge of the facing disk. When cutting and applying the disks of material and adhesive, there is no means of ascertaining whether the desired conditions are present in the completed cap. Consequently, there is always likelihood of imperfectly faced caps being produced.

With the above conditions in mind, I have provided material, in strip form, for facing

bottle caps, in which one surface of the strip is provided with a firmly adherent, continuous thin facing of adhesive, thus avoiding all necessity for assembling strips of facing material and of adhesive tissue preparatory to their use in the bottle cap facing machine, and all of the disadvantages growing out of this practice.

In the strip material of my invention, a very thin stratum of adhesive is evenly distributed upon one face of a strip of facing material. The adhesive is not only firmly bonded to this material, but has a smooth surface finish of sufficient thickness to form the desired firm bond between a disk cut from the strip and the material of the cap to which such disk is cemented.

Furthermore, adhesive tissue must be of a thickness to have sufficient inherent strength to permit of its being stripped from a roll in a mill for working same, and to admit of its being cut to the desired width and to be handled in the winding and the disk applying machines, and during the process of its production it has more or less of a longitudinally extending grain, as distinguished from its normal granular formation.

In the application of heat, when bonding the facing material to the cap, when utilizing adhesive tissue, a tendency of the adhesive is to break up into slightly isolated, small globules, thus interrupting the continuity of the bonding stratum. Whether this is due to irregularities in the surface of the facing strip, or to a shrinkage of the adhesive tissue when fused, I have been unable to determine. In the strip of my invention, however, the adhesive is thoroughly distributed throughout one face of the facing material, and the above conditions do not develop in the subsequent handling of the strips.

It is an object of the present invention to provide a method of producing spot center crowns such that the spots are easily and economically secured to the sealing disks and such that they are firmly secured and not liable to become loosened in use.

With these general objects in view the invention consists in the method which will be first described and then more particularly pointed out in the claims.

According to the method of the present invention, the strip material having a surface which is substantially non-absorbent and gas impervious, such as metal foil, is coated with a substance that is devoid of tackiness when dry and has adhesive qualities when soft. In carrying out the method according to what is considered the best practice the adhesive substance is such that it can be applied cold, i. e. at room temperatures, and is waterproof or insoluble in cold water. While various materials may be used I have found a suitable adhesive in a solution of damar gum and rosin in mineral spirit or turpentine, to which is added 5% or less of a vegetable oil such as soya bean or China-wood oil. The damar gum and rosin may be in the proportion of 35% to the whole. The adhesive may have a drier of lead resinate or the like in a proportion of 2% or less. This adhesive is waterproof and is not weakened by gases or acids, such as are present in the bottle contents with which crown caps are usually employed.

While the coating may be applied to the material in various ways, it is conveniently applied in fluid form and cold to a strip of foil from which the spots are to be cut. So far as the method of producing the strip is concerned, it is such that the effective distribution of the adhesive throughout the entire area of the facing material is assured, and this condition cannot be disturbed as a result of the cutting of discs from this material when in strip form. Furthermore, the adhesive surface may be thoroughly inspected while producing the strip material, so that any imperfect product may be discarded before it reaches the disc applying machine. In this connection it is noted that the spots may be conveniently assembled by feeding a strip of material over successive crown corks and cutting out a disk which is deposited on a cork, such assembling machinery being known in the art.

After the coating is applied to the metal foil it is dried. While this may be effected by air drying at room temperature it is more rapidly accomplished at a temperature of about 300° F. maintained for about 30 minutes. When dried the coating is devoid of tackiness so that the metal foil may be handled without difficulty or trouble. This is particularly advantageous when the metal foil is to be fed in strips because the application of the adhesive is carried out independently of the assembling steps. Moreover, the coating gives the thin metal foil more or less body which facilitates feeding and cutting. Since the adhesive is applied directly to the surface of the facing or spot material and firmly bonded thereto, there is no likelihood of difficulties arising as a result of separation of the adhesive from the facing strip during the spot forming operation, either as a result of poor adherence or from suction or otherwise, such as frequently occurs when using superimposed strips of facing material and of adhesive tissue. Moreover, in handling this material the adhesive stratum is incapable of stretch or distortion relative to the spot strip as frequently occurs in the handling of separate strips of adhesive tissue and facing material where any stretch or distortion of the adhesive stratum results in a defective cap and when the stretch is extreme, tearing of the adhesive tissue makes necessary the stoppage of the cap machine until the strip can be repaired.

After the coating is dry, the metal foil spots

are assembled, coated side down, with the sealing disks. In case the metal foil is fed in a strip, spots may be cut out and deposited on the sealing disk, as above set forth.

At the time of assembly the coating material is softened to render it adhesive and the assembled unit is subjected to pressure. In carrying out the invention according to what is now considered the best practice the coating will be softened by heat after the crown is assembled. In cutting discs from this improved laminated strip having an adhesive stratum bonded thereto, there is no tendency toward mutilation of the adhesive layer by reason of possible drag of the cutting dies, and each disc, as delivered from the die to within a cap, will present a continuous uninterrupted adhesive surface upon the disc so as to insure, by the subsequent application of heat and pressure, a bond between the disc and the cap cushion layer coextensive in area with the disc.

This possibility of securing a clean cut by the dies for forming the discs, both as to the non-absorptive and gas impervious, and as to the adhesive stratum, insures an effective bond entirely about the edge of the spot or disc, thereby presenting a continuous barrier of non-absorptive and gas impervious material at the space between the disc and the cap which will effectively prevent the seepage of gas or fluid in a bottle between the disc and the portion of the cap to which it is applied.

Although the adhesive facing is sufficiently thick to provide an adhesive stratum or layer, it is sufficiently thin to avoid any tendency toward the expression during the application of pressure of any of the adhesive from between the facing material and the portion of the cap to which it is applied. This may be accomplished in any suitable manner, as by a heated plunger or a plunger and heated table. The heat softens the coating and renders it adhesive and the pressure serves to unite the metal foil spot to the cork.

Referring to the accompanying drawings, there is shown suitable mechanism for coating the strip and for cutting discs therefrom and adhesively uniting the disc to caps at the time of the assembly of the discs with the caps. In the drawings,

Figure 1 is a diagrammatical view showing the coating of the strip.

Figure 2 is a longitudinal sectional view of a fragment of the strip.

Figure 3 is a side elevational view partly in section showing one step in the assembly operation.

Figure 4 is a view similar to Figure 3 showing the spot as it is cut and adhesively united to the cap at the time of assembly.

Figure 5 is an interior face view of the completed cap, and

Figure 6 is a cross sectional view of the cap shown in Figure 5.

The strip of facing material should have the characteristic of aluminum foil. That is to say, it should present one surface which is non-absorbent and gas impervious. This strip may be fed from a reel 10 to a reel 11, suitably separated so that the adhesive coating may be applied and hardened between the time any portion of the strip leaves the reel 10 and is wound upon the reel 11. For the purpose of applying the adhesive, the same may be maintained in a trough 12, positioned beneath an adhesive applying roll 13, between which and a roll 14, the strip passes, so that as the rolls are rotated the adhesive is applied to the undersurface thereof. As will be understood, the adhesive hardens between the time it is applied and the winding of the laminated strip upon the reel 11.

The completed spot material or liner is illustrated in Figure 2, and comprises the layer 15 of non-absorbent and gas impervious material, such as aluminum foil having on one surface the coating 16 of adhesive, which is preferably of the character hereinbefore described. This adhesive is waterproof or liquid resistant, and will be normally hard, i. e. non-tacky, at room temperature so that the material may be conveniently handled in strip form, but quickly softens under the application of heat, becoming tacky, so that upon the application of pressure, the laminated disc will be adhesively retained in the cap. The preferred method of applying the material to the cap is to utilize, at the time of assembly, both heat and pressure to unite the spot to the cork or cushion material insert or facing of the cap.

In Figures 3 and 4, there is shown a suitable mechanism for applying the disc and adhesively uniting it to the cork insert at the time the strip is punched from the disc and assembled with the cap.

The cap 17 is of the conventional crown type having an interior facing 18 of cushion material, such as composition cork retained in the cap as by an adhesive layer 17′; the cushion disc and adhesive may be applied to the cap in any suitable manner, for example as described in the patent to Marsa, No. 1,603,786, granted Oct. 19, 1926. The caps, with the cushion discs inserted therein, may be positioned beneath the cutting dies 19, 20, by means of a traveling bed 21 having suitable sockets for receiving the cap so as to position the same accurately beneath the cutting dies. The strip material for forming the spot is fed beneath the die 20 with the adhesive coating 16 facing the cap, and when the die descends it will cut from the strip, which is fed by any suitable means (not shown), a spot or facing 22 of the character illustrated in Figures 5 and 6. The spot or disc is preferably of smaller diameter than the cap facing so as to form a substantially centrally

disposed spot which leaves around its edge an exposed portion of the cushion material adapted to engage the edge of a bottle neck, the spot being of sufficient size to close the bottle mouth and prevent contact of the contents with the cushion material.

As will be observed (Figures 3 and 4) as the punch 20 descends, it cuts from the strip a spot of the size shown in Figure 5, and continued downward movement presses this disc upon the cushion layer 18.

The punch 20 may be maintained at an elevated temperature, as by means of a burner 23, and the temperature should be sufficient to fuse or soften the adhesive coating and make it tacky so that, at the time the disc is assembled with the cap, the heat and pressure will cause the disc to be adhesively united to the surface of the cushion material with sufficient permanency to insure that the position will be retained and avoid likelihood of displacement of the disc thereafter.

The assembled unit is then permitted to cool and the cooling may advantageously be coupled with pressure, for example, by a plunger. Cooling may be effected in any suitable manner, being carried out to the congealing point of the coating material.

The resulting crown has a firmly secured metal foil spot which is not liable to become loose in use owing to the fact that the adhesive substance is not soluble in liquids more commonly sealed by crown corks. Moreover, when the metal foil is assembled with the sealing disk it is already prepared for being stuck in place, the sticking being accomplished by the simple application of heat and pressure. The coating operation is a simple one and the coated metal foil is easily handled because the dry coating is not tacky.

A cap made in accordance with this method possesses the advantage of a substantially uniform and complete distribution of the adhesive layer throughout each spot or facing disc. The method has the advantage of eliminating the labor of associating a separate adhesive strip and a strip of facing material, and the further advantage of enabling higher speeds to be maintained in the facing spot applying machine. The elimination of the danger of breakage of a separate adhesive tissue strip avoids the frequent stoppage of the machine, which was unavoidable due to the handling of the somewhat fragile and elastic adhesive tissue.

What is claimed is:

1. The improved method of manufacturing caps of the type having an interior disc of cushion material provided on its exposed face with a center spot, which comprises providing spot material in strip form having one surface formed of an exposed continuous coating of water resistant adhesive which is normally hard at room temperature but becomes tacky upon the application of heat and having another surface to be exposed to the contents of a capped container, cutting from said strip a facing spot having one surface completely coated with said adhesive with a cap disposed beneath the portion of the strip from which the spot is cut, whereby the cutting operation positions the spot upon the cushion material with the coating between the spot and the cushion material, and upon assembly applying simultaneously to the spot pressure and sufficient heat to render the adhesive tacky, thereby causing the spot to adhere to the cushion material, and thereafter permitting the adhesive to cool and harden.

2. The improved method of manufacturing caps of the type having an interior disc of cushion material provided on its exposed face with a center spot, which comprises providing metal foil spot material in strip form having one surface formed of an exposed continuous coating of water resistant adhesive which is normally hard at room temperature but becomes tacky upon the application of heat and having another surface to be exposed to the contents of a capped container, cutting from said metal foil strip a facing spot having one surface completely coated with said adhesive with a cap disposed beneath the portion of the strip from which the spot is cut, whereby the cutting operation positions the spot upon the cushion material with the coating between the spot and the cushion material, and upon assembly applying simultaneously to the spot pressure and sufficient heat to render the adhesive tacky, thereby causing the spot to adhere to the cushion material, and thereafter permitting the adhesive to cool and harden.

In testimony whereof, I have hereunto set my hand.

ALBIN H. WARTH.

TO THE COMMISSIONER OF PATENTS:-

Your petitioner, Albin H. Warth, a citizen of the United States, residing at Baltimore, in the County of Baltimore and State of Maryland, (whose Post Office address is 38 York Court, Baltimore, Md.) prays that Letters Patent may be granted to him for the new and useful Improvements in Bottle Caps and the Method of Making Same, set forth in the annexed specification; and he hereby appoints Frank T. Wentworth, of 41 Park Row, in the Borough of Manhattan, City, County and State of New York, his attorney with full power of substitution and revocation, to prosecute this application, to make alterations and amendments therein, to sign the drawings, to receive the patent, and to transact all business in the Patent Office connected therewith.

Signed at the County of Baltimore and State of Maryland, this 1st day of May 1929.

Albin H. Warth

TO ALL WHOM IT MAY CONCERN

Be it known that I, Albin H. Warth, a citizen of the United States, residing at Baltimore, in the County of Baltimore and State of Maryland, have invented certain new and useful Improvements in Bottle Caps and the Method of Making Same, of which the following is a specification, reference being had therein to the accompanying drawings, which form a part thereof.

My invention relates to bottle caps and the method of making same, and more particularly to a cap consisting of a metallic shell containing a cushion disk having what is known as a protecting center disk, and to the method of applying this center disk.

Bottle caps of the type to which my invention relates have heretofore been extensively used for sealing bottles containing mineral waters and other fluids having a deleterious action upon the cushion disk within the cap, particularly when this disk is made of composition cork. Ordinarily the facing disk has been made of tin foil cemented or otherwise attached directly to the cushion disk, or secured thereto by means of a fibrous backing having applied thereto a dry adhesive made tacky by means of a thin film of moisture applied to the cushion disk.

It has been attempted to secure the facing disk upon the cushion disk by means of a liquid cement, but this has proven impracticable because, in order to secure a satisfactory bond, it was necessary to apply the adhesive in a quantity having such thickness that, upon the application of pressure to secure the desired intimate relation between the facing disk and the cushion disk, there was a tendency of the disk to slide into an eccentric position in relation to the disk. In order

to permit the effective sealing of a bottle with a cap having a tin center or other protective facing, it is essential that the facing disk be accurately centered in relation to the cushion disk so as to avoid any possibility of the neck of the bottle sealing against the facing disk, since this would result in the presence of minute channels or voids at the point of contact of the facing disk with the neck of the bottle. Furthermore, at the points where the line of contact crossed the periphery of the disk, there would be exposure of a small area of the cushion disk to the contents of the bottle.

With the above conditions in mind, the object of my present invention is to provide a bottle cap having a protecting center disk secured in position by a fusible medium devoid of moisture, and thus avoid any possibility of slippage of the disk while pressing it into the necessary intimate relation with the cushion disk.

The medium used for securing the facing disk in place is of itself insoluble and acid resisting and, being fusible at low temperatures, will form a very thin coating between the facing disk and the cork so as to preclude the possibility, in the event of imperfections in the facing disk, of the cork being attacked by the fluid contents of a bottle.

The cementing medium may be readily handled, is not affected by ordinary changes of temperature or atmospheric conditions, may be readily cut to size simultaneously with the cutting of the facing disk so as to secure a bonding stratum co-extensive with the area of the facing disk, and may be quickly fused to secure the desired bonding action between the facing disk and the cushion disk.

In addition to the foregoing characteristics, I am enabled to effectively use a facing disk of fibrous material,

since the nature of the bonding medium is such as to firmly adhere to hard finished papers as well as to natural cork or composition cork.

In the commercial production of such caps it is essential that the facing disk, during production, be cut from a strip of the material, and since the edges of the disk cannot be protected by the same material used for waterproofing the surface of the disk, I have found it desirable, after the application of the facing disk, to apply, to the entire surface of the cap exposed interiorly of the cap, a very thin protecting surfacing of water repellant material. This not only serves to prevent adherence of the cork to the neck of the bottle, and to exclude atmospheric air from the exposed portions of the cushion disk before the cap has been applied to a bottle so as to prevent darkening of the cork by oxidation, but will at the same time, protect the perimeter of the center facing disk to an extent to minimize likelihood of the absorption of moisture at the edge of the disk.

Bottle caps of the general type to which my invention relates must be produced at a very low cost, and the various materials entering into same and the method of assembling and finishing are matters of great desideratum.

The herein described method of making the bottle cap of my invention relates merely to the manner of applying the center facing disk and finishing the cap, it being understood that the assembling of the metal shell and the mounting of the cushion disk therein are entirely independent operations, preparatory to the practicing of the method of my present invention.

The invention consists primarily in a bottle cap embodying therein a metallic shell, a cushion disk within said

shell, a facing disk of water repellant, gas impervious fibrous material of smaller diameter than, and concentric with, said cushion disk, and a thin stratum of an insoluble, fusible, cementitious material co-extensive in area with said facing disk, between said facing disk and said cushion disk; and in such other novel characteristics as are hereinafter set forth and described, and to the method of making said caps, all as hereinafter set forth and described, and more particularly pointed out in the claims hereto appended.

Referring to the drawings,

Fig. 1 is a bottom plan view upon an enlarged scale of a bottle cap embodying the invention;

Fig. 2 is a section on the line 2-2 of Fig. 1;

Fig. 3 is a vertical section illustrating the first stage of applying the center disk to the cushion disk;

Fig. 4 is a similar view illustrating the final stage; and

Fig. 5 is a view illustrating a stage intermediate those illustrated in Figs. 1 and 2, used when it is desired to apply a wax finish to the cushion disk.

Like letters refer to like parts throughout the several views.

In the accompanying drawings, notwithstanding that the caps themselves are shown upon an enlarged scale, the dimensions of the facing disk and the intermediate bonding stratum are of greatly increased thickness as compared with the actual materials used, even when compared with the enlarged scale of the other parts of the cap.

A bottle cap embodying the invention consists of the usual metallic shell a having a fluted skirt b. Secured within this shell is a cushion disk c which may be either of natu-

ral, or of composition, cork. Composition cork is more extensively used than natural cork, and the employment of a tin or other center facing disk is particularly desirable with composition cork cushion disks, since the contents of a bottle will more readily attack the binder of the composition cork than it will natural cork.

It is essential, to secure a reliable seal, particularly with carbonated beverages, that the neck of the bottle seal directly against the cushion disk, and not against the center facing disk. This is generally understood, and I follow, in the bottle cap of my present invention, the old practice of using a center facing disk d, the diameter of which is relatively less than that of the cushion disk, so that when the cap is applied to a bottle, the lip of the bottle will be positioned between the facing disk and the skirt b, the contacting area being such as to bring the facing disk to a point at the inner edge of such contacting area.

While heretofore tin centers have been extensively used, it has been found impracticable to use paper disks for this purpose, because in order to make them impervious to gas, and non-absorbent, the finish of the paper had to be such as prevented the formation of a sufficiently good bond between the facing disk and the cushion disk to permit the practical commercial production of such caps.

To correct this condition, it has long been the practice to bond a metal foil, such as tin, to a fibrous backing, to which latter the cement would firmly anchor. With this construction of the facing disk it was the practice to apply a dry adhesive to the fibrous backing strip and to make this adhesive tacky by the application of moisture to the cushion disk immediately prior to the coating of the facing strip and the

application of the disk cut therefrom to the cushion disk.

While caps, having a facing disk of the character immediately above described, have been extensively used, their production cost, as compared with the required low cost of such caps, has been very high.

In the cap of my invention, the center disk d is composed of a glazed hard paper, such as is generally known as express paper, sulphite paper or bleached Kraft paper having a waterleaf finish. Such papers are, of themselves, independently of the finish, fairly non-absorbent, and when required for pasting purposes, are usually provided with a dry gummed surface. The process of producing such gummed paper results in a curl in the paper.

While such hard tough papers are extremely desirable because of their inherent non-absorbent, gas impervious qualities, their use in bottle caps of the type to which my invention relates was impracticable, prior to my invention, because of the difficulties of feeding and cutting previously gummed paper, and of cementing same to the cushion disk.

In the cap of my invention, however, to obviate these difficulties, I use ungummed paper of the type above referred to, and secure it to the cushion disk by means of a disk of what is known as gutta-percha tissue, which material, in strip form, may readily be handled in a machine and collated with a facing disk paper strip so as to permit a disk of the paper and a disk of the gutta-percha to be simultaneously cut by the same dies. This not only simplifies the production of the cap, but results in a bonding stratum g between the facing disk and the cushion disk co-extensive in area with the facing disk itself. The strip of paper from which the disk d is cut is indicated at d' while the strip of gutta-percha forming the

stratum g is indicated at g'.

Gutta-percha is particularly desirable as a bonding medium, not only because it ensures the distribution of the bonding stratum throughout the entire area of the facing disk, but because it will readily adhere, when softened to the desired extent, to the cork or composition cork, and to hard paper. Furthermore, it possesses the qualities of being non-absorbent and non-impervious to gases. The tissue itself is very thin, about two thousandths of an inch, and when softened, instantly adheres to the cork and to the paper, and is not subject to side sliding or slippage, such as liquid cements. The gutta-percha is not affected by fruit acids, minerals, CO_2 or other ingredients present in the fluid contents of bottles with which such caps are designed to be used.

The gutta-percha may be fused or melted at temperatures sufficiently low to avoid injury to the other previously assembled portions of the cap, and will return to its former solid form at normal temperatures with considerable rapidity.

In the finished cap, particularly when such caps are desired for use with spring water or mineral waters, it is desirable, after the application of the center disk, to apply a very thin superficial coating f of water repellant material, such as paraffin, Ceresin or other waxes, throughout the exposed faces of the cushion and center disk. This coating serves to prevent adherence of the cushion disk to the neck of the bottle, due to the action of the water upon the cork or upon the binder of composition cork, and also serves to more or less effectively seal the raw edges of the paper of the center disk and prevent possibility of the softening of the paper and its ultimate disintegration as a result of a slow absorption

of moisture through such raw edges.

A cap embodying the invention lends itself to rapid production methods, which will now be described.

Preparatory to the application of the center disk d to the cushion disk c, the latter is completely assembled in relation to the shell a. The caps, completely assembled, may be rapidly fed in relation to cutting dies g and h, and as they are brought under these dies, superimposed strips d' of paper, and c' of gutta-percha tissue are fed between the die plate h and the punch g. With the descent of the punch g, disks are simultaneously cut from the strip d' and c', such disks being pressed by the punch upon the disk d with their centers concentric with each other and with said disk d. The punch g is maintained at an elevated temperature required to melt the gutta-percha of the strip c' and make it tacky, so that substantially simultaneously with the pressing of the disks d and c against the disk c, the disks d and c will be bonded together with sufficient permanency to ensure accurate positioning of the disk c and avoid likelihood of displacement of same thereafter. It is preferable, after the disk c has thus been bonded to the disk d, to thereafter subject them to continuing heat and pressure for a sufficient interval to ensure the complete fusion of the gutta-percha and a close adhesion of every portion of the disk c to the disk d.

For this purpose I have shown a carrier i and a heated spring pressed plunger j.

In the drawings, I have shown the punch g and the plunger j as being heated by gas jets, but this is immaterial to the invention and other heating means may be employed.

It will be noted that by following the methods above specified, the heat necessary for the fusing of the gutta-percha

is applied at the surface of the disk d, and that the time intervals are sufficiently short to avoid any substantial absorption of heat by the cushion disk c. The very thin gutta-percha tissue will melt very rapidly, and after the removal of the punch g or plunger j will solidify with great rapidity and form a substantially imperceptible stratum intermediate the disks c and d.

If it is desired to provide the cap with a superficial wax surfacing throughout the area of the cushion disk c and center disk d, a very small quantity of wax, such as paraffin or Ceresin wax or wax compounds, may be delivered upon said disks within the shell a following the application of the disk d to the disk c, and prior to the application of heat and pressure through the medium of the carrier j and plunger j. Such heat and pressure will spread a drop of wax in a very thin film about the entire exposed face of the two disks, the raw edge of the disk d also being coated with this wax.

The thickness of the disk d will be approximately five thousandths of an inch, while the thickness of the binding stratum s, in the ultimate product, will be relatively less than the thickness of the gutta-percha tissue, or a mere fraction of a thousandth of an inch. The wax surface stratum will also be but a mere fraction of a thousandth of an inch, and is not perceptible to the eye, although sensible to the touch.

The glazed face of the disk d does not require a wax surfacing, and, so far as I have been able to determine, most of the wax is expressed from this surface and forced from the disk to the exposed area of the cushion disk c.

If it is desired to provide the cap with a wax surface as described, it is essential that this surface be applied after the center disk d has been assembled in the cap, since

the presence of wax upon the surface of the cushion disk c, prior to the application of the disk d, would prevent a proper bonding of this disk d to the cushion disk c.

The glazed surface upon the strip g' consists of a waterproof compound consisting of resin, Chinawood oil and a drier, and containing a plasticizer.

Express paper, sulphite paper and bleached Kraft paper are all well known commercial products.

It is not my intention to limit the invention to the precise details herein described, it being apparent that such may be varied without departing from the spirit and scope of the invention.

Having described the invention, what I claim as new and desire to have protected by Letters Patent, is:-

1:- A bottle cap embodying therein a metallic shell, a cushion disk within said shell, a facing disk of water repellant, gas impervious fibrous material of smaller diameter than, and concentric with, said cushion disk, and a thin stratum of an insoluble, fusible, cementitious material co-extensive in area with said facing disk, between said facing disk and said cushion disk.

2:- A bottle cap embodying therein a metallic shell, a cushion disk within said shell, a facing disk of water repellant, gas impervious fibrous material of smaller diameter than, and concentric with, said cushion disk, having a glazed surface exposed inwardly of the shell, and a thin stratum of an insoluble fusible, cementitious material co-extensive in area with said facing disk, between said facing disk and said cushion disk.

3:- A bottle cap embodying therein a metallic shell, a cushion disk within said shell, a facing disk of water repellant, gas impervious fibrous material of smaller diameter than,

and concentric with, said cushion disk, a thin stratum of an insoluble, fusible, cementitious material co-extensive in area with said facing disk, between said facing disk and said cushion disk, and a thin film of wax upon the exposed surface of said cushion disk and about the edge of said facing disk.

4:- A bottle cap embodying therein a metallic shell, a cushion disk within said shell, a facing disk of water repellant, gas impervious fibrous material of smaller diameter than, and concentric with, said cushion disk, and a thin stratum of gutta-percha co-extensive in area with said facing disk, between said facing disk and said cushion disk.

5:- A bottle cap embodying therein a metallic shell, a cushion disk within said shell, a facing disk of water repellant, gas impervious fibrous material of smaller diameter than, and concentric with, said cushion disk, having a glazed surface exposed inwardly of the shell, and a thin stratum of gutta-percha co-extensive in area with said facing disk, between said facing disk and said cushion disk.

6:- A bottle cap embodying therein a metallic shell, a cushion disk within said shell, a facing disk of water repellant, gas impervious fibrous material of smaller diameter than, and concentric with, said cushion disk, a thin stratum of gutta-percha co-extensive in area with said facing disk, between said facing disk and said cushion disk, and a thin film of wax upon the exposed surface of said cushion disk and about the edge of said facing disk.

7:- The method of making the herein described bottle cap, including the steps of simultaneously cutting disks from superimposed strips of fibrous material, and insoluble, fusible cementitious material, depositing said disks upon a cushion disk positioned within a metallic shell, and applying heat

sufficient to fuse said cementitious material while subjecting said disk to pressure.

8:- The method of making the herein described bottle cap, including the steps of simultaneously cutting disks from superimposed strips of fibrous material, and insoluble, fusible cementitious material, depositing said disks upon a cushion disk positioned within a metallic shell, applying heat sufficient to fuse said cementitious material while subjecting said disk to pressure, and thereafter subjecting said disk to a continuing heat and pressure.

9:- The method of making the herein described bottle cap, including the steps of simultaneously cutting disks from superimposed strips of fibrous material, and insoluble, fusible cementitious material, depositing said disks upon a cushion disk positioned within a metallic shell, applying heat sufficient to fuse said cementitious material while subjecting said disk to pressure, delivering a small quantity of wax upon said disks, and thereafter subjecting said disk to a continuing heat and pressure.

10:- The method of making the herein described bottle cap, including the steps of simultaneously cutting disks from superimposed strips of fibrous material, and gutta-percha tissue, depositing said disks upon a cushion disk positioned within a metallic shell, and applying heat sufficient to fuse said gutta-percha tissue while subjecting said disk to pressure.

11:- The method of making the herein described bottle cap, including the steps of simultaneously cutting disks from superimposed strips of fibrous material, and gutta-percha tissue, depositing said disks upon a cushion disk positioned within a metallic shell, applying heat sufficient to fuse said gutta-percha tissue while subjecting said disk to pressure,

and thereafter subjecting said disk to a continuing heat and pressure.

12:- The method of making the herein described bottle cap, including the steps of simultaneously cutting disks from superimposed strips of fibrous material, and gutta-percha tissue, depositing said disks upon a cushion disk positioned within a metallic shell, applying heat sufficient to fuse said gutta-percha tissue while subjecting said disk to pressure, delivering a small quantity of wax upon said disks, and thereafter subjecting said disk to a continuing heat and pressure.

In witness whereof I have hereunto affixed my signature, in the presence of two subscribing witnesses, this 1st day of May 1929.

Thomas E. Robertson
Commissioner of Patents.

January 23, 1930

Applicant: Albin H. Warth

Frank T. Wentworth
41 Park Row
New York, N. Y.

Ser. No. 360,895
Filed May 6, 1929
For BOTTLE CAPS AND THE METHOD OF MAKING SAME.

This case has been examined and the following art is cited:

Alberti et al	1,401,300	Dec. 27, 1921	113-80
Taliaferro	1,486,937	Mar. 18, 1924	" "
Alberti	1,199,026	Sept. 9, 1916	215-39
Stahl	1,215,737	Feb. 13, 1917	" "

This application contains claims to two independent inventions.

Claims 1 to 6 cover the bottle cap classifiable in Class 215-39 in Division 40, while claims 7 to 12 cover the method of making bottle caps, classifiable in Class 113-80 in Division 14. Cancelled July 23

The caps covered by claims 7 to 12 may be made in other ways than by the method of claims 1 to 6.

Division is required between these two groups of claims.

As indicating the state of the art after a cursory examination, attention is called to the above cited patents.

Room 102 Annex. Paper No. 3.

In the matter of the application of
Albin H. Warth, for Bottle Caps and the Method of Making Same,
Filed May 6th 1929, Serial No. 360,895.

Hon. Commissioner of Patents,
Washington, D. C.

Sir:-

In response to the communication of Jan. 23rd 1930, from the Examiner in charge of the above entitled matter, applicant elects to prosecute the present application as to claims 1 to 6. Cancel claims 7 to 12. An early action on the merits is respectfully requested.

In order to expedite the prosecution of the case, it is desired to point out that the patent to Alberti et al, No. 1,401,300 relates to a machine for producing a cap similar to that shown in the Alberti patent No. 1,199,026. Both of these patents are owned by applicant's assignee. The Alberti patent No. 1,199,026 discloses a center spot cap, the facing disk 15 of which is a metal foil secured to the cork cushion disk 13 by means of an albuminous cement. This has nothing to do with the claims of the present application.

The Stahl patent, No. 1,215,737 refers to an air space 14, within the shell of which is a paper cap 12, an annular sealing disk 11, a laminated facing consisting of a layer of jute paper stock, a layer of gutta-percha and a thin layer of paper tissue. This bears no resemblance to the cap of the application.

The patent to Taliaferro relates to a method of forming a bottle cap having an unvulcanized rubber composition cushion. This has nothing to do with the structure of the application.

1317

1561

It is thought, in view of the foregoing, that the claims are clearly allowable over the art referred to by the Examiner.

Respectfully submitted,

Alvin D. Wait

by Frank P. Wentworth

Heil/M

FILED
JUN 28 1930

Please find below a communication from the EXAMINER in charge of this application.

Thomas E. Robertson
Commissioner of Patents.

Applicant: A.H. Warth,

Ser. No. 360,895,
Filed May 6, 1929,
For BOTTLE CAPS AND THE METHOD OF MAKING SAME.

Frank T. Wentworth,
41 Park Row,
New York, N.Y.

Responsive to amendment filed Feb. 26, 1930.

Claims 1, 2, 3, 4, 5 and 6 are novel over Alberti of record in that gutta-percha is used as a sealing means. Stahl in Fig. 2, 18 shows gutta-percha as a sealing means. Also the fibrous facing disc, glazed surface of the shell, and wax film on the cushion disc, are novel over Alberti, but no new results or advantages have been pointed out for these changes. The metallic facing disc of Alberti accomplishes the same work as the fibrous disc in the claim. To improve the Alberti device by adding to it the novel feature of Stahl, together with the novel features for which no advantage is seen, would amount to an aggregation of old ideas. These claims are therefore rejected over the state of the art.

August 29, 1930.

Hon. Commissioner of Patents,
Washington, D. C.

Sir:-

In response to the Official Action of June 28, 1930, kindly amend the above entitled application as follows:

IN THE SPECIFICATION:

Page 10:

Line 6, after "plasticiser" insert --In other words the paper is varnished--.

IN THE CLAIMS:

Add the following:-

--15. A facing for bottle caps of the type employing a cushion layer comprising glazed, hard paper having on one exposed side a coating of varnish, and on the other a backing of gutta-percha adapted to adhesively unite the facing to the cushion layer.

1321

1565

14. In a bottle cap of the type which includes an interior layer of cushion material, a facing overlying said layer and consisting of hard, glazed paper having on one exposed side a coating of varnish, and on the other side facing said layer a backing of gutta-percha adhesively united to both the layer and paper.

15. As a new article of manufacture, paper having a high gloss and having a coating of varnish on one surface of the paper, and a coating of gutta-percha on the other surface.--

Add'l

REMARKS

In response to the last Official action, Counsel desire to point out that the use as a liner of a glazed, hard paper varnished on one surface and having a gutta-percha backing or coating has been recognized as patentable; attention is called to the patent to Lange No 1,758,610. Claim 15, added by this amendment is the claim of the Lange patent with which an interference is requested.

The attention of the Examiner is directed to page 8 of the specification, which describes the method of stamping or punching the discs of gutta-percha and paper by means of a heated plunger, as follows:

> "Preparatory to the application of the center disk d to the cushion disk c, the latter is completely assembled in relation to the shell a. The caps, completely assembled, may be rapidly fed in relation to cutting dies g and h, and as they are brought under these dies, superimposed strips d' of paper, and e' of gutta-percha tissue are fed between the die plate h and the punch g. With the descent of the punch g, disks are simultaneously cut from the strip d' and e', such disks being pressed by the punch upon the disk d with their centers concentric with each other and with said disk d."

In this manner, the paper and gutta-percha are united by the heat and pressure applied by the punch and attention is directed to the statement immediately following:

> "The punch g is maintained at an elevated temperature required to melt the gutta-percha of the strip e' and make it tacky, so that substantially simultaneously with the pressing of the disks d and g against the disk c, the disks d and g will be bonded together with sufficient permanency to insure accurate positioning of the disk g and avoid likelihood of displacement of same thereafter".

In other words, applicant forms a composite liner in this manner by adhesively uniting with the gutta-percha, as set forth, glazed hard paper, as described on page 6, beginning at line 6: -

> "In the cap of my invention, the center disk d is composed of a glazed hard paper, such as is generally known as express paper, sulphite paper or bleached Kraft paper having a waterleaf finish".

This paper has its exposed surface coated with a varnish, as described on page 10 of the specification, line 4, in the sentence reading:-

> "The glazed surface upon the strip e' consists of a waterproof compound consisting of resin, Chinawood oil and a drier and containing a plasticiser".

Lange describes not only the use of varnished glazed paper but also the uniting of the same with gutta-percha tissue. Note the following statement in the patent specification on Page 1, line

> "The cork insert or liner may be protected by a sheet of varnished paper, the unvarnished surface of which is bonded to the cork by a material such as gutta-percha. The gutta-percha in sheet form may be applied to the unvarnished surface of the sheet of varnished paper and blanks may be stamped from this composite material and applied to the cork insert by hot pressing."

Obviously, applicant goes further than Lange and effects, by hot pressing, an adhesive uniting of the gutta-percha sheet

with the paper almost simultaneously with the uniting of gutta-percha with the cushion layer of the cap. This is not, of course, disclosed by Langé and has the advantage of making the entire product, including both the liner and cap, in a single operation.

But it is apparent that, so far as the broad idea is concerned, both parties describe and claim the same steps and produce the same final product to wit: a liner consisting of (a) hard glazed paper, (b) varnish on one surface of the paper, and (c) a coating of gutta-percha on the other surface, the gutta-percha serving to adhesively unite the liner to the cushion layer of a cap.

Respectfully,

Cushman, Byron & Brady
Attorneys.

Thomas E. Robertson
Commissioner of Patents.

Applicant: Albin H. Warth

Cushman, Bryant & Darby,
Washington Loan & Trust Bldg.,
Washington, D. C.

Ser. No. 360,895
Filed May 6, 1929
For Bottle Caps and the Method of Making Same

In response to communication filed Aug. 30, 1930:-

Additional reference made of record:-

Lange 1,758,610 May 13, 1930:- 91-68K

This application has been transferred to this division (Division 50) solely for the purpose of deciding the interference issue raised by applicant by copying the claim of the above cited patent.

Claim 15 is rejected to applicant for the reason that he cannot properly make his claim.

First, the said claims calls for an "article of manufacture"; i. e. the liner exists as such independently of the assembled cap. In applicant's construction, the caps, completely assembled, are fed to the cutting dies g and h, and, as they are brought under these dies, superimposed strips d' of paper, and e' of gutta percha tissue are fed between the die plate h and the punch g. The punch g is mantained at an elevated temperature whereby the gutta percha tissue is rendered tacky and the disc d is bonded to the cork cushion c. The patentee, on the other hand, first produces the liner and then applies it to the cork insert by hot pressing (page 1, lines 40 to 45). Obviously, then, applicant, in view of his disclosure, does not have a structure which responds to the "article of manufacture" of said Claim 15.

Secondly, the claim recites a "coating of gutta percha". Referring to the specification of the patent it is found that the gutta percha is applied in the form of a solution, the solvent being

1327

1571

suitably driven off to leave f thin film of gutta percha. Patentee specifically refers to the objections and disadvantages resulting from the use of gutta percha in thin sheet form (page 3, lines 41 to 56) and seeks to escape these objectionable results by applying the adhesive in liquid form, which is expressed in the claim by the word "coating". Applicant does not apply the gutta percha in liquid form as a coating but rather in thin sheet form. Consequently, this claim does not read upon applicant's disclosure inasmuch as he has disclosed no application of the adhesive in liquid form to provide a coating.

In accordance with the practice enunciated in ex parte Weber and Woodford, C. D. 1919, 65 , applicant is given twenty (20) days from the date of mailing of this letter to respond to this action.

E. Blake

Examiner.

APPLICATION DIV. U.S. PATENT OFFICE OCT 27 30

IN THE UNITED STATES PATENT OFFICE

Albin H. Warth,

BOTTLE CAPS AND METHOD OF MAKING SAME,

Filed May 5, 1929,

Serial No. 360,895.

U. S. PATENT OFFICE
OCT 28 1930
DIVISION 50

Division 50.

October 27, 1930.

Hon. Commissioner of Patents,

Washington, D. C.

Sir:-

In response to the Official action of October 7, 1930, this application is submitted for reconsideration.

The Examiner states that the applicant cannot make claim 15 for two reasons:

First: The applicant does not apply a gutta percha coating in the form of a solution comprising a solvent which dries out to precipitate a thin film of gutta percha; whereas the term "coating", as used in the claim means gutta percha applied in liquid or solution form with a solvent.

Second: Applicant does not disclose an article of manufacture, i. e., a liner existing as such independently of an assembled cap.

It is fundamental that claims presented in an application must be given the broadest interpretation to which they are reasonably susceptible; and this is particularly true when there is involved a question of interference. The Examiner's attention is directed to

the decision of the Court of Appeals in the District of Columbia in In re Levy, 2 Fed. (2d) 939. In this case the applicant, Levy, sought an interference with the Armstrong patent No. 1,342,885, and the Court said:

> "(1) The Assistant Commissioner ruled that Armstrong had in mind the employment of very high frequency, and he therefore read that limitation into the claims. But, over and over again, we have ruled that claims must be given the broadest interpretation which they reasonably will support, and that a party will not be permitted to narrow his claim to suit the exigencies of a particular situation. Miel v. Young, 29 App. D. C. 481; Lindmark v. Hodgkinson, 31 App. D. C. 612; Cox v. Headley, 48 App. D. C. 341, 265 F. 981. The party who states his claims before the Patent Office in broad language is not in a position, when thrown into interference, to read limitations into them. The reason is obvious. If he has asked too much, he may reform his claims in an appropriate proceeding. When he takes claims broader than his invention, however, he thereby is enabled unduly to harass the public."

Not only must the claims presented by the applicant be given the broadest possible interpretation their terms can properly support, but every doubt must be resolved in favor of the applicant's right to make such a claim. In the same case, the Court of Appeals emphasized this in the following language:

> "(2, 3) It appearing that the Assistant Commissioner failed to give these claims the broad interpretation of which they reasonably were capable, and that when so interpreted they probably would have been allowable to the applicant, we follow our usual course and resolve any doubt in applicant's favor."

At this point we desire to make clear that we are not urging that the Examiner broadly interpret the terms in the Lange claim, but merely that he must

broadly interpret the claim which the applicant presents. Since this claim is identical with the claim of the patent, we do not see how the Examiner can properly avoid declaring an interference.

"COATING" IS A GENERIC TERM;
IT APPLIES TO ANY COVERING LAYER.

It being clear that the claim (15) must be interpreted as broadly as its terms will reasonably permit, it seems proper to inquire, first, what is the usual meaning of the word "coating".

We will refer to (A) the dictionary definitions of the term, and (B) the accepted meaning of the term in the bottle cap art.

A. Webster's New International Dictionary defines:

coating: (1) a coat, or covering; a layer of any substance as a cover or protection;

coat: n. (7) a layer of any substance covering another;

coat: v. to cover with a layer of any substance.

Collier's New Dictionary of the English Language (57th Edition) contains the following definition:

coat: a thin layer and integument.

B. It is customary in this art to define as a coating, a stratum of rubber or gutta percha, which is disposed in the identical position disclosed by the applicant and applied in a similar manner. For example, attention is called to the patent to Koch, No. 1,238,156, August 28, 1917. This patent shows a laminated liner comprising (1) a layer C of gutta percha, (2) a layer D

of paper, (3) a layer E of soft vulcanized rubber, and (4) a layer F of metal foil. These various layers are first inserted in the cap, and then, when properly arranged, the cap is heated in an oven, so that the gutta percha and rubber soften. The gutta percha melts and adheres both to the cork disc and to the paper. This is described in the specification, p. 1, lines 64-95.

The claims of the Koch patent define the layer C of gutta percha as a "coating". For example, claim 3 defines it as "a fusible coating or layer of gutta percha applied to the inner side of said sheet". Claim 4 also refers to the gutta percha as a coating.

APPLICANT'S GUTTA PERCHA IS A "COATING".

If the Examiner will now refer to the disclosure in this application, it will be clear to him that this application fully supports the ordinary meaning of the term "coating" as defined in the dictionary, and, furthermore, describes a coating in exactly the sense this term is used in the art, as indicated by the Koch patent.

The specification makes clear that the gutta percha spot is positioned beneath the paper and that the descent of the heated punch melts the gutta percha and makes it tacky. This causes the gutta percha to be bonded or united to the paper. The specification says:

> "simultaneously with the pressing of the discs 1 and 2 - - the discs 1 and 2 will be bonded together with sufficient permanency to ensure accurate positioning of the disc 2 - -".

To emphasize more fully the bonded, adhesive relation of the gutta percha and paper discs, the specification says:

> "It is preferable, after the disc e has thus been bonded to the disc d to thereafter subject them to continuing heat and pressure for a sufficient interval to ensure the complete fusion of the gutta percha and a close adhesion of every portion of the disc d to the disc e."

It is evident from this description that the gutta percha forms a coating or thin film upon the surface of the disc.

The specification and drawing describe and illustrate the gutta percha as a bonded surface upon the paper.

Moreover, the specification makes clear that the stratum of gutta percha is extremely thin, for it says:

> "The very thin gutta percha tissue will melt very rapidly, and after the removal of the punch f or plunger i, will solidify with great rapidity and form a substantially imperceptible stratum intermediate the disks e and d."

Hence it is clear that the stratum of gutta percha provided by the applicant is identical with the stratum described in the Koch patent, and which Koch has, with the approval of the Patent Office, defined as a "coating" upon his paper. Moreover, it fully responds to the dictionary definitions of the term "coating", and, obviously, these definitions indicate the usual and proper significance of the word.

The grant of the Koch patent shows that the term "coating" applies and accurately describes applicant's use of gutta percha. To hold that the applicant's structure

does not support a reasonable interpretation of the term would be inconsistent with the action of the Patent Office in approving the use of the same definition by Koch to describe a corresponding use of a gutta percha film.

The Examiner has stated that the term "coating" in the Lange claim means "coating obtained from a gutta percha solution". Now, the applicant is not concerned with the meaning of this word as used in the claim of the Lange patent. Lange may have intended to obtain a patent upon a solution coating, but the fact remains that he did, in fact, obtain a claim which covers a coating in its broadest sense. That Lange may have intended to use this word in a limited sense seems to be immaterial, at least to applicant's right to a patent containing the claim (15) which he now presents, for the reason that the applicant is not seeking a patent upon the subject matter of the Lange disclosure, but upon the invention which the applicant discloses.

The applicant claims to be the first to produce a cap liner comprising paper of the class described (high gloss) having a varnish surface on one side and a coating or layer of gutta percha on the other side in union with the paper. The application discloses (1) paper of this character, (2) the varnish coating, and (3) the gutta percha coating. Although the gutta percha coating is applied by means of tissue, the specification describes that this tissue is fused or bonded to the paper, and, therefore, it covers or coats the surface of the paper. The fact that this gutta percha constitutes a coating is not altered by the

further fact that, at the same time it is applied to the paper, the entire liner is inserted in the cap. This is merely an incident in the process adopted by the applicant for producing the liner.

It would be impossible to obtain the fusion of the gutta percha to the paper, which the specification describes, unless the gutta percha completely coats or covers the surface of the paper disc. This result is not in any way modified by the fact that simultaneously the applicant utilizes the softened gutta percha to unite the paper to the cork disc. He does this instead of permitting the gutta percha to harden and thereafter softening the same in exactly the same manner to effect the union of the discs with the cork.

"ARTICLE OF MANUFACTURE" IS A GENERIC EXPRESSION - IT MAY BE PROPERLY APPLIED TO A PART OF A MANUFACTURED DEVICE.

Since the Examiner has held that applicant does not disclose an article of manufacture, it is apparent that he is under the impression that a development to constitute an article of manufacture must not be merely a part of a complete article. Now such an interpretation of the expression is not in accord with the settled meaning of the term "manufacture" as used in the Statute, or the customary meaning of the term as employed in issued patents. The Statutory meaning of "manufacture" has been frequently defined by the Courts. It is a very broad term, and Judge Acheson in Johnson V. Johnston, (C. C.) 60 Fed. 618, 620, stated that:

> "The term 'manufacture,' as used in the patent law, has a very comprehensive sense, embracing whatever is made by the

> art or industry of man, not being a machine, a composition of matter, or a design."

Walker on Patents (4th Ed. Sec. 17) states:

> "Whatever is made by the hand of man and is neither of these (i.e., an art, a machine, a composition of matter, or a design), is a 'manufacture,' in the sense in which that word is used in the American patent laws."

In Riter-Conley Mfg. Co. v. Aiken (C. C. A. 3d Cir.), the Court held that either a building or a part of a building is a manufacture and may be patented as such if it involves novelty or invention. In that case Judge Buffington said:

> "To say that a roof falls within the domain of architecture is not to decide the question; for the question is not whether a roof construction is included in architecture, which, of course, it is, but whether the roof section here in question is, in view of its several constituent and co-operating elements, a manufacture. We must not be misled by the factors of size or immobility. The pyramids, by reason of their bulk and solidity, are none the less a manufacture, as distinguished from a natural object."

The Examiner is requested particularly to note this decision, since the Court made clear that a part of a building, e. g., roof, may be claimed as an article of manufacture just as the applicant is here claiming part of the complete cap shown in the drawing.

Furthermore, in the case of International Mausoleum Co. v. Sievert, the Circuit Court of Appeals for the 6th Circuit in referring to the above quoted decision of Judge Buffington, had this to say:

> "That case (as does also the opinion of Judge Orr in the District Court (205 Fed. 531) contains an interesting discussion of the question under consideration. It seems clear that the making of the various

parts of the mausoleum would be manufacture. The subject, in our opinion, does not lose its nature from the mere fact of the bringing of the parts together in a complete whole."

Consequently, it is clear from these decisions of the Circuit Court of Appeals of the 3d and 6th Circuits, as well as from the broad definitions of the invention appearing in the earlier cases, that the Examiner should not construe "article of manufacture" to mean only a complete manufactured article; it may be, and frequently is, a part of a complete article just as applicant's liner is a part of his complete cap.

Now, with reference to the accepted meaning of the term "article of manufacture", in this particular art of caps and cap liners, we again refer the Examiner to the Koch patent, mentioned above, and also to the patent to Weiseenthanner, No. 857,698, June 25, 1907.

The specification of the Koch patent describes clearly that the four (4) layers of liner material are, one after another, inserted in the cap, and that thereafter the cap is subjected to heat. The claims of this patent do not include the cap as an element, but define merely the liner as an article of manufacture. Each claim of this patent is identical in form or character with claim 15 of the present application. For example, claim 3 reads:

"As a new article of manufacture, a cover for bottle cap corks, comprising an outer surface layer of metal foil, an intermediate sheet of flexible material, an adhesive coating of soft rubber connecting the said sheet and metal foil, and a fusible coating or layer of guttapercha applied to the inner side of the said sheet."

This patent, therefore, constitutes a clear precedent for a claim of the form presented, and other patents could readily be called to the Examiner's attention, viz; the patent to Weissenthanner, above mentioned.

The patent to Koch and the patent to Weissenthanner do not disclose a liner or "cover", as an article which exists independently of the cap, i. e., prior to its assembly with the cap. In other words, the inventions which Koch and Weissenthanner have patented, as articles of manufacture, do not exist until assembled with a cap. (See specification of Koch, page 1, lines 65 to 96 and Weissenthanner, page 2, lines 44 to 47).

It will be clear that both of these patents claim articles of manufacture and describe liners which are not completely formed until with a cap.

APPLICANT DISCLOSES A LINER AS AN ARTICLE OF MANUFACTURE.

The above cited decisions and the patents mentioned show that this application fully supports the usual meaning of "article of manufacture" and its accepted meaning in the art to which the present invention relates. It is, therefore, believed that the Examiner will desire to reconsider his holding that the term "article of manufacture" as applied to a lining must mean a liner formed prior to the construction of the cap and existing independently of the cap. To interpret the expression in this way is not in accord with either the past actions of the Patent Office in the grant of earlier patents or with the decisions of the Court bearing on the meaning of "manufacture".

The claim (15) does not state that the liner is formed prior to or independently of its assembly with the cap.

It is clear from applicant's disclosure that he forms the liner at the same time he assembles same with the cap, but the claim makes no reference to the method of its manufacture or to the time of manufacture. The claim defines merely the finished liner and this article as defined in the claim is disclosed in both the specification and drawings.

The liner as an article of manufacture is made by the applicant and in the form defined is present in the finished product.

The Examiner should observe that there is a clear distinction between the question here presented and that considered by the Commissioner in Ex parte Howard 1924 C. D. p. 75. In that case, the applicant was attempting to claim an article which existed only at an intermediate stage of a process and which did not appear as such in the final product. Consequently, it was held that this article was not a "manufacture", as defined by the Statute. The Commissioner said:

> "The article claims are drawn to a freely-falling drop or gob of molten glass. The drop exists as such only while falling to the mold. When it reaches the latter, it assumes a different shape, solidifies immediately, and is transformed into a completed article. In view of the decisions cited, I am of the opinion that it is the finished product that the patent statutes are designed to protect as 'manufactures' and not something which is produced at a particular stage of the manufacturing process and which is evanescent and adapted for use only in so far as it may enter into and be modified by subsequent steps of a method for producing a completed article.

> "In reaching this conclusion I am not unmindful of the fact that products of intermediate steps of a process or method may be inherently useful and new, and therefore may be patented as articles. Thus a roof is a 'manufacture' within the meaning of section 4886, Revised Statutes, and in constructing a roof the builder may also fabricate the clay tiles, beams, bolts, rivets, etc., used in forming the same, each of which would be intermediate products and, if new, patentable as a 'manufacture'. These articles, however, are inherently useful and complete in themselves. Nothing remains to be done to make a finished product. On the other hand, the drop of glass claimed is in its temporary condition while being transformed into something else. The 'manufacture' is not yet made, the process of manufacturing is still incomplete."

In the present case, the liner appears in the final product, and in the precise form defined. Hence, it is a distinct element of the cap and an article of manufacture. Of course, it is associated with a cap, just as a roof may be constructed with a house, but as pointed out in the decisions above cited, this constitutes no reason why it cannot be claimed as an article of manufacture.

In other words, the claim (15) is directed to a sub-combination or sub-element of the complete device, and, so far as this claim is concerned, it is immaterial whether the liner is manufactured prior to its assembly with the cap or simultaneously with the assembly operation, as disclosed by the applicant. As the Examiner will observe, there is no suggestion in the claim that the paper is in sheet or strip form, nor is there any limitation requiring its production prior to assembly with the cap.

It has been repeatedly held that an applicant

may claim as an article of manufacture any part of an article or machine which is useful and constitutes an entity in the final product or machine.

In the case of Roberts v. H. P. Nail Co., 53 Fed. 920, the Court said:-

> "In a combination patent it is permissible for the patentee, after claiming his whole machine, to claim also the combination of fewer parts than the whole, provided the combination of the parts is new, even if, taken along, the combination will not result in any known useful product. This is fully established in the decision of Judges McKennan and Nixon in the case of Wells v. Jaques, 5 O. G. 364. In that case the patent was for a combination of elements making up a hat-body machine. The combination embodied a great many different parts, and the patentee made quite a number of claims, of which one only embodied the whole machine. It was objected that only the claim for the whole machine was valid, because the devices in combination in the other claims could not be employed alone for any useful purpose, and, only being useful when combined into a complete machine, the patent should have been for the unit, and not for the different combinations. To this objection Judge Nixon says:
>
> > 'I cannot yield assent to that proposition. The separate claims of a patent must be construed in reference to the specifications; and, if the specifications point out the arrangements to be made, or the methods to be adopted, in connection with other instrumentalities which the inventor may not claim as new, in order to render his invention practically useful, the test to be applied is not whether the claim alone will produce a useful result, but whether it will do so supplemented by and in connection with such designated devices and instrumentalities.'"

The same question was presented in the case of Chambers-Bering-Quinlan Co. v. Fairas, 75 Fed. 663, and in subsequent cases, such as Thomson-Houston Elec. Co. v. Black River Traction Co., 135 Fed.763, where the

> "Many subcombinations, although new, are not useful, except to perform their appropriate functions in the machine of which they are a part. The description in the patent of the whole machine, and of the means or mode by which the subcombination is brought into co-operative relation with the other parts, usually indicates how the subcombination may effect a useful result. When this is so, the combination need not be operative alone, because (to use the language of Mr. Walker) 'utility is justly ascribed to things which have their use in cooperating with other things to perform a useful work.'".

In the case of National Metal Casting Company v. American Steel Foundries, 182 Fed. 639, a similar ruling was adhered to. In Wright Co. v. Herring-Curtiss Co., 204 Fed. 607, the Court said:

> "In such circumstances, as I read the authorities, the claim is valid as a subcombination. Thomson-Houston Electric Co. v. Black River Traction Co., 135 Fed. 759, 68 C. C. A. 461; Deering v. Winona Harvester Works, 155 U. S. 286, 15 Sup. Ct. 1187, 39 L. Ed. 153; Taylor et al v. Sawyer Spindle Co., 75 Fed. 301, 22 C. C. A. 203. In Railroad Co. v. Dubois, 12 Wall, 47, 20 L. Ed. 265, the Supreme Court of the United States says:
>
> > "Undoubtedly a patentee may claim and obtain a patent for an entire combination, or process, and also for such parts of the combination or process as are new and useful, and he may claim and obtain a patent for both."

CONCLUSION.

It is submitted that this application presents a disclosure which justifies the applicant (1) in defining the invention as an "article of manufacture" and (2) in defining the gutta percha as a "coating" for the paper. And it is submitted that if these

terms are given their proper meaning and the broadest meaning to which they are reasonably susceptible, the Examiner cannot logically reach a contrary conclusion.

Respectfully,

Attorneys for Applicant.

Hon. Commissioner of Patents,

Washington, D. C.

Sir:

Supplementing the amendment of Oct. 27, 1930, we hereby authorize and request entry of the following amendments in the above entitled application.

IN THE SPECIFICATION

No Amendment
See Amendment D

Page 10

Line 6 after the matter inserted by amendment of Aug. 29, 1930, insert the following: --The varnish described provides a film which is insoluble. That is to say, the film is insoluble in acetic acid, citric acid, tartaric acid, and carbonic acid, and it is also insoluble in alcoholic beverages of such alcoholic percentage as may be ordinarily obtained for human consumption. The Chinawood oil is typical of oils which are resistant to alcohol and, therefore, makes the varnish alcohol resisting or insoluble.--

C'

Per E

IN THE CLAIMS

Add the following:

1343
1587

Re E

--16. A composite material of the character described ~~for use in container~~ caps comprising a layer of sheet material, a protecting film of varnish adhering to one surface of said layer of sheet material, a layer of resilient material, and a waterproof adhesive bonding said resilient material to the other surface of said layer of sheet material, whereby the adhesive is protected from the action of contained beverages by the film of varnish and a composite material impervious to moisture is formed.

C

17. A composite material of the character described ~~for use in container caps~~ comprising a layer of sheet material, a protecting film of varnish adhering to one surface of said layer of sheet material, a layer of fibrous material, and a waterproof adhesive bonding said fibrous material to the other surface of said layer of sheet material, whereby the adhesive is protected from the action of contained beverages by the film of varnish and a composite material impervious to moisture is formed.

18. (Claim 1.) A composite material of the character described comprising a layer of sheet material, an insoluble film of varnish adhering to one surface of said layer of sheet material, a layer of resilient material, and a waterproof adhesive bonding said resilient material to the other surface of said layer of sheet material, whereby the adhesive is protected from the action of solvents by the film of varnish and a composite material impervious to moisture is formed.

19. (Claim 2.) A composite material of the character described comprising a layer of sheet material, an alcohol resistant film of varnish adhering to one surface of said layer of sheet material, a layer of resilient material and a waterproof adhesive bonding said resilient material to the other surface of said layer of sheet material.

20. (Claim 3.) A composite material of the character described comprising a layer of sized paper, an insoluble film of varnish adhering to one surface of the paper, a layer of resilient material, and a film of waterproof adhesive bonding said resilient material to the other surface of the paper, whereby the adhesive is protected from the action of solvents by the film of varnish and a composite material impervious to moisture is formed.

21. A composite material of the character described comprising a layer of sheet material, an insoluble film of varnish adhering to one surface of said layer of sheet material, a layer of resilient material and a waterproof adhesive bonding said resilient material to the other surface of said layer of sheet material, said insoluble film of varnish consisting of the dried residue of a varnish comprising a resin and an oil the dried film of which is resistant to alcohol.

111/50

22. A composite material of the character described comprising a layer of sheet material, an insoluble film of varnish adhering to one surface of said layer of sheet material, a layer of resilient material and a waterproof adhesive bonding said resilient material to the other surface of said layer of sheet material, said insoluble film of varnish consisting of the dried residue of a varnish comprising resin and an oil the dried film of which is resistant to alcohol.

23. A composite material of the character described comprising a layer of sheet material, an insoluble film of varnish adhering to one surface of said layer of sheet material, a layer of resilient material and a waterproof adhesive bonding said resilient material to the other surface of said layer of sheet material, said insoluble film of varnish consisting of the dried residue of a varnish comprising resin and Chinawood oil.

24. (Claim 8.) A composite material of the character described comprising a layer of sheet material, an insoluble film of varnish adhering to one surface of said layer of sheet material, a layer of resilient material and a waterproof adhesive comprising gutta percha bonding said layer of resilient material to the other surface of said sheet material, whereby the adhesive is protected from the action of solvents by the film of varnish and a composite material impervious to moisture is formed.

3TT/51

25. (Claim 9.) A composite material of the character described comprising a layer of sheet material, an insoluble film of varnish adhering to one surface of said layer of sheet material, a layer of fibrous material, and a waterproof adhesive bonding said fibrous material to the other surface of said layer of sheet material, whereby the adhesive is protected from the action of solvents by the film of varnish and a composite material impervious to moisture is formed.

C'

26. In a container cap and as a liner therefor, a composite material comprising a layer of sheet material, a protecting film of varnish adhering to one surface of said layer of sheet material and a waterproof adhesive bonded to the other surface of said layer of sheet material, whereby the adhesive is protected from the action of contained beverages by the film of varnish and a composite material impervious to moisture is formed.

27. In a container cap and as a liner therefor, a composite material comprising a layer of sheet material, a protecting film of varnish adhering to one surface of said layer of sheet material and a waterproof adhesive in the form of gutta percha bonded to the other surface of said layer of sheet material, whereby the adhesive is protected from the action of contained beverages by the film of varnish and a composite material impervious to moisture is formed.--

REMARKS

The Examiner's attention is called to the fact that a number of the foregoing claims have been copied from the patent to Lange, No. 1,779,884, granted October 28, 1930. A number of the other claims are slightly broader

than the patent claims, and are submitted at this time so that the record may be clear that applicant is claiming the broad subject matter.

With respect to the broader claims, it will be noted that claims 16 and 17 are based upon claims 1 and 9 of the Lange patent.

Claims 26 and 27 are somewhat similar to claims which were cancelled by the patentee directed to a three layer material, to wit: varnish, paper and gutta percha, and do not refer to the cushioning material. This two layer material is clearly disclosed by the applicant and is formed when assembled with the cushion material. So that the Examiner may readily observe the identity of applicant's claims with those of the patent, we have noted the patent claims in connection with those which have been copied exactly. On other words, it will be observed that applicant has copied in exactly the form appearing in the patent claims 1, 2, 3, 8 and 9.

Claims 4, 5 and 6 of the patent appear in substance in this amendment as claims 21, 22 and 23.

The specification has been amended to set forth the inherent characteristics of the varnish described, and a supplemental oath covering this amendment will be filed.

It is requested that an interference be promptly declared.

Respectfully,

Cushman, Darby & Cushman
Attorneys.

Albin H. Warth

BOTTLE CAPS & METHOD OF MAKING SAME,

Filed May 5, 1929,

Serial No. 360,895 Div. 50.

October 31, 1930

Hon. Commissioner of Patents,

Washington, D. C.

Dup

Sir:

Supplementing the amendment of Oct. 27, 1930, we hereby authorize and request entry of the following amendments in the above entitled application.

IN THE SPECIFICATION

Page 10

Line 8 after the matter inserted by amendment of Aug. 29, 1930, insert the following: ---The varnish described provides a film which is insoluble. That is to say, the film is insoluble in acetic acid, citric acid, tartaric acid, and carbonic acid, and it is also insoluble in alcoholic beverages of such alcoholic percentage as may be ordinarily obtained for human consumption. The Chinawood oil is typical of oils which are resistant to alcohol and, therefore, makes the varnish alcohol resisting or insoluble.--

IN THE CLAIMS

Add the following:

--16. A composite material for use in container caps comprising a layer of sheet material, a protecting film of varnish adhering to one surface of said layer of sheet material, a layer of resilient material, and a waterproof adhesive bonding said resilient material to the other surface of said layer of sheet material, whereby the adhesive is protected from the action of contained beverages by the film of varnish and a composite material impervious to moisture is formed.

17. A composite material for use in container caps comprising a layer of sheet material, a protecting film of varnish adhering to one surface of said layer of sheet material, a layer of fibrous material, and a waterproof adhesive bonding said fibrous material to the other surface of said layer of sheet material, whereby the adhesive is protected from the action of contained beverages by the film of varnish and a composite material impervious to moisture is formed.

18. (Claim 1.) A composite material of the character described comprising a layer of sheet material, an insoluble film of varnish adhering to one surface of said layer of sheet material, a layer of resilient material, and a waterproof adhesive bonding said resilient material to the other surface of said layer of sheet material, whereby the adhesive is protected from the action of solvents by the film of varnish and a composite material impervious to moisture is formed.

19. (Claim 2.) A composite material of the character described comprising a layer of sheet material, an alcohol resistant film of varnish adhering to one surface of said layer of sheet material, a layer of resilient material and a waterproof adhesive bonding said resilient material to the other surface of said layer of sheet material.

20. (Claim 3.) A composite material of the character described comprising a layer of sized paper, an insoluble film of varnish adhering to one surface of the paper, a layer of resilient material, and a film of waterproof adhesive bonding said resilient material to the other surface of the paper, whereby the adhesive is protected from the action of solvents by the film of varnish and a composite material impervious to moisture is formed.

21. A composite material of the character described comprising a layer of sheet material, an insoluble film of varnish adhering to one surface of said layer of sheet material, a layer of resilient material and a waterproof adhesive bonding said resilient material to the other surface of said layer of sheet material, said insoluble film of varnish consisting of the dried residue of a varnish comprising a resin and an oil the dried film of which is resistant to alcohol.

22. A composite material of the character described comprising a layer of sheet material, an insoluble film of varnish adhering to one surface of said layer of sheet material, a layer of resilient material and a waterproof adhesive bonding said resilient material to the other surface of said layer of sheet material, said insoluble film of varnish consisting of the dried residue of a varnish comprising resin and an oil the dried film of which is resistant to alcohol.

23. A composite material of the character described comprising a layer of sheet material, an insoluble film of varnish adhering to one surface of said layer of sheet material, a layer of resilient material and a waterproof adhesive bonding said resilient material to the other surface of said layer of sheet material, said insoluble film of varnish consisting of the dried residue of a varnish comprising resin and Chinawood oil.

24. (Claim 8.) A composite material of the character described comprising a layer of sheet material, an insoluble film of varnish adhering to one surface of said layer of sheet material, a layer of resilient material and a waterproof adhesive comprising gutta percha bonding said layer of resilient material to the other surface of said sheet material, whereby the adhesive is protected from the action of solvents by the film of varnish and a composite material impervious to moisture is formed.

25. (Claim 9.) A composite material of the character described comprising a layer of sheet material, an insoluble film of varnish adhering to one surface of said layer of sheet material, a layer of fibrous material, and a waterproof adhesive bonding said fibrous material to the other surface of said layer of sheet material, whereby the adhesive is protected from the action of solvents by the film of varnish and a composite material impervious to moisture is formed.

26. In a container cap and as a liner therefor, a composite material comprising a layer of sheet material, a protecting film of varnish adhering to one surface of said layer of sheet material and a waterproof adhesive bonded to the other surface of said layer of sheet material, whereby the adhesive is protected from the action of contained beverages by the film of varnish and a composite material impervious to moisture is formed.

27. In a container cap and as a liner therefor, a composite material comprising a layer of sheet material, a protecting film of varnish adhering to one surface of said layer of sheet material and a waterproof adhesive in the form of gutta percha bonded to the other surface of said layer of sheet material, whereby the adhesive is protected from the action of contained beverages by the film of varnish and a composite material impervious to moisture is formed.--

_R_E_M_A_R_K_S_

The Examiner's attention is called to the fact that a number of the foregoing claims have been copied from the patent to Lange, No. 1,779,884, granted October 28, 1930. A number of the other claims is slightly broader

than the patent claims, and are submitted at this time so that the record may be clear that applicant is claiming the broad subject matter.

With respect to the broader claims, it will be noted that claims 16 and 17 are based upon claims 1 and 9 of the Lange patent.

Claims 26 and 27 are somewhat similar to claims which were cancelled by the patentee directed to a three layer material, to wit: varnish, paper and gutta percha, and do not refer to the cushioning material. This two layer material is clearly disclosed by the applicant and is formed when assembled with the cushion material. So that the Examiner may readily observe the identity of applicant's claims with those of the patent, we have noted the patent claims in connection with those which have been copied exactly. In other words, it will be observed that applicant has copied in exactly the form appearing in the patent claims 1, 2, 3, 8 and 9.

Claims 4, 5 and 6 of the patent appear in substance in this amendment as claims 21, 22 and 23.

The specification has been amended to set forth the inherent characteristics of the varnish described, and a supplemental oath covering this amendment will be filed.

It is requested that an interference be promptly declared.

Respectfully,

_____

Attorneys.

Applicant: Albin H. Warth

Ser. No. 360,895
Filed May 6, 1929
For Bottle Caps and The Method of Making Same

NOV 24 1930

Responsive to amendment filed Oct. 31, 1930.

The following additional reference is made of record:

Lange 1,779,884 Oct. 28, 1930 154-45.5

Applicant's argument of Oct. 27, 1930, relative to claim 15 has been considered but the examiner sees no reason for changing his attitude as expressed in the office letter of Oct. 7, 1930.

In this connection, applicant's attention is invited to in re Bijur 398, O.G. 355, from which it will be clear that the terms used by Lange in defining his composite stock material cannot be disregarded.

On reconsideration, claim 13 also is rejected as applicant cannot make this claim. Applicant does not at any time make such a paper as is defined by this claim as a separate identity.

Claim 14 is for a bottle cap examinable in Division 40.

Applicant does not give in his description such a full statement of his glazed surface on page 10 in lines 4-6, as will now support the function attributed to this varnish by the insertion after line 8, page 10, by the amendment of Oct. 31, 1930.

Applicant is, therefore, required to cancel the insertion after line 8, page 10, by the amendment of Oct. 31, 1930.

Applicant is further notified that the directions for this insertion are confusing because they refer to an amendment of Aug. 29, 1930, whereas there is no such amendment, the amendment of the earlier date having been made in line 6, page 10.

Claims 16-27, inclusive, are rejected as applicant has never

5131

disclosed such a composite material as is referred to in these claims whereas the material of Lange is a separate identity or material and so described and claimed by Lange in patent 1,779,884.

Claims 16 and 17 are further rejected as broader than the disclosure as any varnish will not do nor has applicant gone into any detail in his description asto the character of varnish necessary for the purpose whereas the Lange patent 1,779,884 is clear on this point.

Claims 18 and 20 are further rejected as applicant has no basis herein for his reference as to an "insoluble film of varnish".

Claim 19 is further rejected as applicant does not give all the characteristics of his varnish wherefrom it may be stated that the film is alcohol resistant.

Claim 20 is further rejected because applicant does not disclose the use of sized paper.

Claims 21 and 22 are further rejected as there is no basis herein for applicant's reference in this claim to the dried residue of a varnish nor is there any basis in the disclosure for the use of any resin and any oil which is resistant to alcohol.

Claim 23 is rejected also for a reason similar to that last mentioned, i.e., applicant does not disclose how his waterproof glazed surface is made.

Applicant is furthermore required to cancel claims 21-27 as being divisible from the bottle cap claims to which applicant has already elected to restrict this case.

Stock material such as is disclosed and claimed by Lange 1,779,884 is classified and examined in Division 56, class 154-45.5 whereas the bottle cap itself is examinable in Division 40.

Inasmuch as a patent could not possibly issue to applicant

1357

1601

Ser. No. 360,895. Sheet #3.

on this application as to claims 21-27, inclusive, no interference will be declared.

In accordance with the practice set down in ex parte Weber and Woodford, C.D. 1919, page 65, applicant is required to respond to this rejection prior to Dec. 13, 1930, and prepare this case for appeal as indicated in the decision referred to.

This action is taken by the examiner in Division 56 upon transfer of this case from Division 50 because applicant has copied claims from a patent granted in Division 56, i.e., the Lange patent cited above.

The rejection of claim 15 originally made in Div. 50 is here repeated after consideration of applicant's argument and conference with the examiner in charge of Division 50 and in view of the examiner's action herein regarding claims 16-27, inclusive, it was apparent that claim 13 should be rejected for the same reason, this action being taken to expedite the prosecution of the case.

Porter
Examiner.

U.S. APPLICATION DIV. NOV 28 30 U.S. PATENT OFFICE

IN THE UNITED STATES PATENT OFFICE

Albin H. Warth

BOTTLE CAPS AND THE METHOD OF MAKING SAME,

Filed May 6, 1929

Serial No. 360,895. Div. 56.

U. S. PATENT OFFICE NOV 29 1930 DIVISION 56

November 28, 1930

Hon. Commissioner of Patents,

Washington, D. C.

Sir:

We hereby authorize and request entry of the following amendments in the above entitled application.

IN THE SPECIFICATION

It is requested that the amendatory matter submitted in the last amendment be inserted at page 10, line 6, after the amendatory matter previously inserted at that line.

REMARKS

In the light of a recent interview kindly granted applicant's attorneys by the Primary Examiner, reconsideration of the refusal to declare an interference between this application and the Lange patent #1,779,884, is respectfully requested.

Applicant has copied for interference purposes claims 1, 2, 3, 8 and 9 of this patent; these claims of the patent are respectively, 18, 19, 20, 24 and 25 of this application.

The rejection of this group of claims seems to be based upon the following principal grounds, namely:

(A). Applicant does not disclose the composite material as a separate identity or article from a cap.

(B). Applicant does not disclose an insoluble film of varnish.

(C) Applicant does not disclose an alcohol resistant film of varnish(claim 19).

(D) Applicant does not disclose sized paper (Claim 20).

Each of the above grounds of rejection will be separately discussed, and it is believed that the Examiner upon considering the following remarks, which cover the same arguments advanced at the interview, will order that the interference be promptly declared.

(A). APPLICANT DOES NOT DISCLOSE THE COMPOSITE MATERIAL AS A SEPARATE IDENTITY OR ARTICLE FROM A CAP.

This ground of rejection is obviously based upon the premise that the claims of the Lange patent are limited to a material which is formed prior to its assembly with the cap. Plainly, both the patentee and the applicant are concerned with the manufacture of a liner for a cap. The first paragraph of the patent specification states that the invention relates "to a composite material especially adapted for the purpose of providing a liner for bottle caps". Applicant discloses a process for forming a similar liner, but instead of assembling the various layers of the liner outside the cap, he positions the cap,with the cushion layer already inserted,beneath cutting dies (Fig. 3), so that the final steps of the assembly are completed within the cap. Nevertheless, the complete article, as formed by the applicant, corresponds exactly to the complete article produced by the patentee.

Although the patentee shows the material in the drawings removed from a cap, he states distinctly in his specification that this material may be formed in exactly the same manner described by the applicant. Note particularly the first paragraph of the specification, p. 2, l. 6-14, which reads:

> "the material may in a sense be absembled within the container cover. For example, the paper may be coated, or otherwise provided with films of varnish and adhesive. The resilient material may be inserted in the container cover and thereafter the varnished and adhesive coated paper may be applied to the fibrous material within the container cover or cap."

From this statement in the specification, it is apparent that the patentee sought claims which would cover his laminated cap-liner material whether (1) completely assembled outside the cap and then inserted, or (2) partially assembled or formed in the cap.

Furthermore, a reading of the claims shows that they are not limited to a material in sheet or strip form, but cover clearly a material produced in accordance with the above quoted statement in the patent specification. Not a single claim of the patent mentions that the material is in sheet or strip form. Moreover, many of the claims state that the material is "impervious to moisture". Note particularly the last lines of claims 1, 3, 8 and 9, each of which has been copied by the applicant. Obviously, the material would not be impervious to the moisture unless it is inserted in a cap. since one surface of the cushion layer is not protected by a moisture impervious facing or spot. It is true that applicant's spot does not extend over the entire surface of the cushion material, but it does extend over as much of the

333/66

cushion material as is exposed to the bottle contents; hence applicant's composite material is impervious to moisture throughout the entire area exposed to the container contents.

Therefore, in view of the plain language of the specification which distinctly describes a mode of manufacture almost identical with that described in the present application and in view of the broad language of the claims, we submit that it is evident the patentee intended to cover a laminated material of the character specification, regardless of whether this material is produced outside a cap or inside a cap, as described by the applicant.

Aside from this statement in the specification of the patent, the fact that the applicant positions his cushion layer within a cap before he applies the other two layers (adhesive and spot material) thereto, constitutes an additional feature of the applicant's invention. In other words, applicant goes a step further than the patentee specifies in his claim and effects a complete assembly of the several layers with the cap at the same time that he assembles the layers. Manifestly, it does not constitute a patentable variation of the applicant's invention to apply the adhesive and spot layers to the cushion material before the latter is inserted in a cap.

(B). APPLICANT DOES NOT DISCLOSE AN INSOLUBLE FILM OF VARNISH.

Admittedly, the applicant did not state that the surfacing which he applies to the paper is varnish or an insoluble varnish, but the specification (p. 10, l. 5) does contain the following statement:

JJJ 47

"The glazed surface upon the strip d' consists of a waterproof compound consisting of resin, Chinawood oil and a drier, and containing a plasticizer."

The above quoted sentence describes not only a varnish, but an insoluble varnish in the sense of the term insoluble is used in the specification of the Lange patent.

Webster's New International Dictionary (1925 Edition) defines "varnish":

"A more or less viscid liquid (usually a solution of resinous matter in an oil or volatile liquid) which, when spread upon a surface, dries either by evaporation or chemical action, forming a hard lustrous coating capable of resisting more or less the action of air and moisture."

Definitions similar to the above will be found in other dictionaries, and we submit that it is impossible to find a definition of varnish which is not fully answered by the above quoted portion of the specification. The definition quoted specifies as the only essential characteristics of varnish (1) the resinous matter and (2) the oil or drier. Applicant states that his surface consists of (1) resin (2) Chinawood oil, and (3) a drier.

As to whether this composition described by the applicant constitutes an <u>insoluble</u> varnish, we must first understand what the patentee means by the word "insoluble". The patent specification states p. 1. l. 80-84:

"In general it may be stated that by insoluble varnish is meant a varnish which is insoluble or inert to such solvents as alcohol, acetic acid, citric acid, and carbonic acid."

Admittedly, applicant does not explain <u>why he uses a varnish of the character described</u> in the specification, but by the last amendment he did explain this when he said:

"The varnish described provides a film which is insoluble. That is to say, the film is insoluble in acetic acid, citric acid, tartaric acid and carbonic acid etc."

This additional matter inserted in the specification is definitely covered by a supplemental oath which accompanied the amendment and which the Examiner will find in the Official file. The insertion does not constitute new matter, as suggested by the Examiner, for the reason that it merely discloses essential and inherent characteristics of the composition set forth in the original specification. To any one familiar with the resistant action of varnishes and compositions of the nature described, it would be apparent that any composition produced in the manner explained, would be resistent to the various acids mentioned. Whether the applicant's composition is insoluble is, of course, a question of fact; but the applicant states, under oath, that it is insoluble in these acids, and we believe the Examiner will be unable to find anything which would support him in controverting this statement. If the Examiner desires affidavits additional to those of the applicant covering the statement that the composition employed by the applicant is insoluble, we will be pleased to furnish the same. But we submit that such affidavits are unnecessary in view of the applicant's own supplemental oath and the further fact that this question will be fully considered in the interference.

If the Examiner will consider for a moment the reason why applicant provides this surface, he will appreciate that there is every reason to conclude that applicant's composition is insoluble, rather than to conclude to the contrary. Why did the applicant provide this composition surface? Is it not provided for the purpose of protecting the paper from the beverage contents? As the Examiner knows, the

applicant is a highly skilled inventor in this art and for years he has been working upon the problem of protecting the composition layers of caps from the contents of bottles with which these caps are used. The applicant is the Chief Chemist of the Crown Cork & Seal Company, assignee of this application, and for many years has been devoting himself to the problem of protecting the composition cork liners by means of suitable moisture and acid proof facings. Is it natural, therefore, that in producing an improvement having as its primary object to afford this protection, the applicant would provide an exposed varnish surface not adapted to protect the underlayers from the acids which are usually present in the beverages with which these caps are employed? Merely to state the question is to answer it in view of the extended experience of the applicant and his avowed purpose in providing the glazed surface.

(C). APPLICANT DOES NOT DISCLOSE AN ALCOHOL RESISTANT FILM OF VARNISH (CLAIM 19).

This objection relates primarily to claim 19 (claim 2 of the patent) which specifies "an alcohol resistant film of varnish". By reference to the above quoted portion of the specification (p. 10, l. 5-6) it will be observed that applicant states his surface composition includes Chinawood oil. The patentee also uses Chinawood oil, and with reference to this ingredient states (p. 3, l. 75 et seq.):

> "Cumar gum may be compounded largely with certain of the oils which are resistant to alcohol, such as for example Chinawood oil .. -".

Hence it is apparent that the patentee's varnish is resistant to alcohol because of the inclusion of Chinawood oil. Manifestly, the applicant's composition is also resistant to alcohol, since it includes the same alcohol re-

sistant ingredient.

(D). APPLICANT DOES NOT DISCLOSE SIZED PAPER (CLAIM 20).

This objection relates primarily to claim 20, which is claim 3 of the patent. This claim specifies "a layer of sized paper".

The applicant has described that he employs express paper, for he says:

> "In the cap of my invention the center disc d is composed of glazed hard paper, such as is generally known as express paper etc."

Express paper is officially defined as a highly polished calendared or sized paper, and in this connection the Examiner's attention is called to the hand-book of official definitions of paper available in his division. This book is believed to be on the desk of the Assistant Examiner, Mr. Chandler.

CONCLUSION

It is believed that the foregoing remarks will completely satisfy the Examiner as to the applicant's right to make claims 1, 2, 3, 8 and 9 of the patent, which claims are numbered, respectively, 18, 19, 20, 24 and 25 in this application.

Claims 13, 14 and 15 will not be discussed, since it is thought unnecessary to do so in this amendment, for the reason that an interference is being declared involving claim 15 and the earlier issued Lange patent (1,756,610) from which the claim was copied. In regular course, applicant will present a motion to shift the burden of proof in that interference and, consequently, there seems to be no occasion to discuss at this time the applicant's right to

make the claim in this case. For the same reason claim 13 will not be discussed. The requirement of division with respect to claim 14 is noted.

Claims 16 and 17. These claims are not taken from the patent, but are similar to claims of the Lange patent. The rejection upon the ground that the claims are broader than the disclosure is believed improper for the reason that, as pointed out in the above quoted definition of varnish, any varnish is resistant to water. Consequently, if the cap is to be used only for closing water containers, any varnish would be suitable. This holding that the use of the broad term "varnish" is not proper is inconsistent with the allowance of the earlier Lange patent 1,758,610, which covers a paper having one surface coated with varnish; no reference is made in the claim of this patent to any particular characteristics of the varnish. It is submitted that since any varnish would be suitable for some purposes, it is not necessary that the broad claims be restricted to an insoluble varnish.

Claims 21 and 22. The objection to these claims on the ground that applicant does not disclose a "dried residue" of the varnish is improper for the reason that applicant specifically discloses that his varnish contains "a drier". Obviously, therefore, when this drier functions, what remains after the drying period is a varnish residue.

It is submitted that an interference should be declared between this application and claims 1, 2, 3, 8 and 9 of the Lange patent 1,779,884, granted Oct. 28, 1930.

Respectfully,

JJD:U

Attorneys.

Address only "The Commissioner of Patents, Washington, D. C." and not any official by name

DEPARTMENT OF COMMERCE
UNITED STATES PATENT OFFICE
WASHINGTON

All communications regarding this application should give the serial number, date of filing, and name of the applicant

Please find below a communication from the EXAMINER in charge of this application.

Dec. 2, 1930.

Thomas E. Robertson
Commissioner of Patents.

Cushman, Bryant & Darby
Wash. Loan & Trust Bldg.,
Washington, D.C.

Applicant: A.H.Wartn

Ser. No. 360,895
Filed May 6, 1929
For Bottle Caps & the Method of Making Same.

MAILED
DEC 2 1930

Responsive to amendment filed Nov. 28, 1930.

Claims 13 and 15 are properly rejected for reasons of record.

Applicant is again required to cancel the insertion after line 8, page 10, for reasons of record.

Claims 16 and 17 are rejected for reasons of record, since applicant does not disclose a composite material for use in bottle caps.

Claims 18 and 20 are properly rejected as applicant's disclosure is not sufficient to support the "insoluble film of varnish"referred to in these claims.

Claim 19 likewise is rejected as there is no basis herein for applicant's claim for an alcohol resistant film of varnish.

Some resins are entirely soluble in alcohol and some partly, and a few nearly insoluble. It is necessary that the proper resin be selected that will mix with China Wood oil. Lange has disclosed this composition and applicant has not. For this reason applicant will not be allowed claims which refer to the character of the varnish.

Claims 21 and 22 are again rejected because of their reference to a varnish film resistant to alcohol.

As indicated above, applicant will not be allowed claims herein for the function of a varnish where no specific varnish was disclosed.

Claim 23 is rejected for reasons of record, i.e., applicant made no disclosure originally or even now of a specific

varnish which will be insoluble under stated conditions.

The mere fact that the varnish actually used by applicant is actually insoluble in the liquids and solutions mentioned in the insertion in line 8, page 10, has no bearing on the question as to whether applicant has a right to make the claims. The right to make the claims rests with the disclosure.

Claims 24 and 25 are rejected because of the inclusion of an insoluble film of varnish.

The rejection of claims 26 and 27 on the grounds stated in the last office letter, i.e., that they are drawn to a liner material as a separate identity is withdrawn.

Claims 26 and 27 are properly examinable in Division 40.

Claims 15, 18, 19, 20, 24 and 25 are FINALLY REJECTED.

Limit of appeal under ex parte Weber & Woodford C.D. 1919 p. 65 - December 23, 1930.

Examiner.

IN THE UNITED STATES PATENT OFFICE

U.S. APPLICATION DIV. U.S. PATENT OFFICE

DEC - 3 30

[illegible] Warth,

BOTTLE CAPS & METHOD OF MAKING SAME,

Filed May 5, 1929,

Serial No. 360,895. Div. 56.

16/E + aff't not book

December 3, 1930

Hon. Commissioner of Patents,
Washington, D. C.

Sir:

In response to the Official action of Dec. 2, 1930, kindly amend the above entitled application as follows:

IN THE SPECIFICATION

Page 10, line 6 cancel the amendatory matter inserted by the amendment of October 31, 1930, and substitute: --A varnish compound of this character provides a film which is insoluble. By insoluble, I means a film which will resist the action of acetic acid, citric acid, tartaric acid, and carbonic acid, in such proportions as these acids are usually found in beverages ordinarily obtainable for human consumption. It also is resistant to alcohol in such percentages as alcohol is ordinarily found in beverages. As a matter of fact, any such varnish is insoluble in liquids containing an extremely high percentage of citric acid, tartaric acid and carbonic acid. The Chinawood oil is typical of oils which are resistant to alcohol and, therefore, causes the varnish to be alcohol resistant or insoluble.--

E'

IN THE CLAIMS

Claim 16, lines 1 and 2 and claim 17, line 1 cancel "for use in container caps" and substitute --of the character described.--

REMARKS

The Examiner is respectfully requested to reconsider the final rejection of claims 18, 19, 20, 24 and 25. He is also requested to withdraw the action upon claim 15, as well as the limit of appeal, since the question of applicant's right to make this claim in the present case will be

settled by motion in an interference now being declared between another application and the Lange patent 1,758,610.

With respect to claims 18, 19, 20, 24 and 25, the rejection of these claims may be divided into two distinct grounds:

1. Claims 18, 20, 24 and 25 on the ground that applicant does not disclose an insoluble film of varnish, and

2. Claim 19 on the ground that applicant does not disclose an alcohol resistant film of varnish.

These grounds of rejection raise what is primarily a question of fact, namely whether any varnish compounded in the manner described in the specification would be (a) insoluble, or (b) resistant to the action of alcohol. In order that the Examiner may be entirely satisfied as to the propriety of the amendment in the specification (p. 10, l. 6), we present herewith the applicant's affidavit. This affidavit states that any conventional or standard varnish compound of Chinawood oil and a resin, regardless of the character of the resin and the relative proportions of the oil and resin, will be (a) insoluble in acids (acetic acid, tartaric acid and carbonic acid) at least in the percentages these acids are present in the usual beverages, and (b) resistant to alcohol in the percentages alcohol is present in beverages. As a matter of fact, the affidavit shows that any such varnish composition will resist tartaric acid and carbonic acid, regardless of the percentage of acid present.

We believe that in view of the decision of the Court of Appeals in re Colay 401 O. G. p. 4 (Dec. 2, 1930), the Examiner will now concede that applicant may properly describe the composition disclosed in the specification as an insoluble or alcohol resistant varnish. It is re-

1371
1615

quested, therefore, that an interference be promptly declared between this application and the Lange patent 1,779,884, and it is believed that this interference should involve as counts claims 1, 2, 3, 8 and 9 of said patent.

Respectfully,

Attorneys.

APPLICATION DIV. PATENT OFFICE DEC -3 30

U. S. PATENT OFFICE DEC 4 1930 DIVISION 56

IN THE UNITED STATES PATENT OFFICE

Albin H. Warth,

BOTTLE CAPS & THE METHOD OF MAKING SAME,

Filed May 6, 1929,

Serial No. 360,895, Div. 56.

- - -

DISTRICT OF COLUMBIA:SS.

ALBIN H. WARTH, being first duly sworn, deposes and says:

I am the applicant identified in the above entitled application, and am Chemical Director of the Crown Cork & Seal Company, Inc., assignee of said application. For approximately fifteen (15) years I have been associated with this Company in connection with chemical work, and for approximately thirteen (13) years have been directing the chemical activities of this Company. My work, as a chemist during this period, has had to do, among other things, with the development of materials and compounds used in the coating of caps and of interior facings or liners for caps. One of the principal and most generally used compounds in this work is varnish.

I have read the Official Action of December 2, 1930, which questions whether the disclosure originally filed supports a claim directed to (a) an insoluble film of varnish, or (b) an alcohol resistant film of varnish.

The specification, as originally signed by me and filed in the United States Patent Office, in referring to the

finish or glaze upon the paper strip states:

> "The glazed surface upon the strip d' consists of a waterproof compound consisting of resin, Chinawood oil and a drier, and containing a plasticizer."

My object in providing this glazed surface was to provide an impervious surface for the paper, and as made clear in the specification I was dealing with caps of the type used generally with beverages, such as ginger ale, grape, cider, near bear, citrate of magnesia, etc. Consequently, I provided and sought to disclose in this application a surface coating or varnish which would withstand the action of the acids (acetic, tartaric, citric and carbonic) and also the relatively small amount of alcohol present in such liquids.

I was not concerned with, and make no claim that I disclosed, a varnish composition which would withstand the action of pure alcohol or pure acetic acid. Since I was providing a surface for use in a definite art, namely the capping of liqids, and particularly beverages, I was concerned with, and therefore intended to provide and disclose a varnish composition which would resist the action of acetic acid and alcohol when present in the percentages usually found in such liquids.

Furthermore, I intended to disclose and for the reasons set forth below, did in fact disclose, a composition which would withstand the action of carbonic acid, citric acid, or tartaric acid, regardless of the percentage of these acids present in the capped liquids.

The use of varnish in the cap manufacturing industry, and particularly in the manufacture of crown caps, extends back over a period of not less than fifteen (15) years. Furthermore, varnish has been used to protect the interior

facing of caps for over twelve (12) years. As a result, the relative proportions of resin and oil in varnish compounds employed in this art have become standardized. They vary from a proportion of one hundred pounds of resin to fifteen gallons of oil, constituting "a short-oil varnish," to a proportion of one hundred pounds of resin to thirty-five gallons of oil, which constitutes a "long-oil varnish". In view of these standardized proportions, anyone skilled in this art, if instructed to prepare a varnish from resin and Chinawood oil, would naturally employ proportions within this range.

I aver, as a fact based upon my own experiments and observations, that a varnish consisting of any resin whatsoever, Chinawood oil and a drier, regardless of the proportions used within the standard range customarily employed in this art, would be insoluble when used with beverages containing citric acid and carbonic acid. Furthermore, any such varnish would be insoluble in beverages of the character above identified containing the usual proportions of tartaric and acetic acid.

With respect to the alcohol insolubility of any such varnish, I aver that it would be insoluble in beverages containing alcohol in the percentages ordinarily found. In this connection, I aver such varnishes will resist alcohol in percentages far exceeding the percentage of alcohol ordinarily present in beverages of the character identified, since these beverages are by law limited to and have an alcohol content not in excess of one-half of one per-cent by volume. While it is true that some resins are soluble in alcohol, it is to be observed that the composition specified in my application includes Chinawood

oil which is insoluble in alcohol and, therefore, this oil when combined with an alcohol soluble resin makes the varnish coating resistant to alcohol and insoluble in such percentages of alcohol as are present in the usual beverages.

Therefore, it is my opinion, based upon work in this art extending over the period above mentioned, that any one skilled in the art, upon reading the sentence in my specification which I have above quoted, would prepare a varnish composition which is for all practical purposes insoluble in the various acids mentioned, insofar as use of the varnish in the capping of beverages or similar liquids is concerned. And I aver that anyone skilled in the art and with the use of varnishes for the purpose explained, would recognize that a varnish compound of the character described, is provided for this acid and alcohol resisting purpose.

Further Deponent sayeth not.

Albert H. Wentz

Ser. No. 366,895
Filed May 6, 1929
For Bottle Caps & Method of Making Same.

The case, above referred to, is forwarded to the Examiner of Interferences because it is adjudged to interfere with others, hereafter specified. The question of priority will be determined in conformity with the Rules. The interference will be identified as No. 60931 On or before JAN 19 1931 the statement demanded by rule 110 must be sealed up and filed with the subject of invention, and name of party filing it, indorsed on the envelope. The subject-matter involved in the interference is

Count 1. A composite material of the character described comprising a layer of sheet material, an insoluble film of varnish adhering to one surface of said layer of sheet material, a layer of resilient material, and a waterproof adhesive bonding said resilient material to the other surface of said layer of sheet material, whereby the adhesive is protected from the action of solvents by the film of varnish and a composite material impervious to moisture is formed.

Count 2. A composite material of the character described comprising a layer of sheet material, an alcohol resistant film of varnish adhering to one surface of said layer of sheet material, a layer of resilient material and a waterproof adhesive bonding said resilient material to the other surface of said layer of sheet material.

Count 3. A composite material of the character described comprising a layer of sized paper, an insoluble film of varnish adhering to one surface of the paper, a layer of resilient material, and a film of waterproof adhesive bonding said resilient material to the other surface of the paper, whereby the adhesive is protected from the action of solvents by the film of varnish and a composite material impervious to moisture is formed.

Count 4. A composite material of the character described comprising a layer of sheet material, an insoluble film of varnish adhering to one surface of said layer of sheet material, a layer of resilient material and a waterproof adhesive comprising gutta percha bonding said layer of resilient material to the other surface of said sheet material, whereby the adhesive is protected from the action of solvents by the film of varnish and a composite material impervious to moisture is formed.

Count 5. A composite material of the character described comprising a layer of sheet material, an insoluble film of varnish adhering to one surface of said layer of sheet material, a layer

1379

1623

Ser. No. 360,895 - 2.

of fibrous material, and a waterproof adhesive bonding said fibrous material to the other surface of said layer of sheet material, whereby the adhesive is protected from the action of solvents by the film of varnish and a composite material impervious to moisture is formed.

The interference involves your application above identified and a patent for Composite Material for Containers, No. 1,779,884, granted Oct. 28, 1930 to Louvern C. Lange, whose post-office address is c/o Standard Insulation Company, East Rutherford, New Jersey, whose attorneys are Pennie, Davis, Marvin and Edmonds, 165 Broadway, New York, N.Y.

The relation of the counts of the interference to the claims of the respective parties is as follows:

(matter)

IN THE UNITED STATES PATENT OFFICE

Albin H. Warth,

BOTTLE CAPS & METHOD OF MAKING SAME,

Filed May 5, 1929,

Serial No. 360,695 Div. 56

* * *

Hon. Commissioner of Patents,
Washington, D. C.

Sir:

We hereby authorize and request entry of the following amendments in the above entitled application.

IN THE SPECIFICATION

Page 1.

Line 12, after "disk" cancel the remainder of the sentence, including the "comma" and substitute --of smaller diameter than the cushion disk.--

Line 18, after "facing" insert --center--.

Page 2.

Line 18, before "insoluble" insert --water--.

Line 22, after the period insert the following: --A medium which is itself elastic or resilient, such as gutta percha, is preferred, since the same will provide an elastic cushion for the fibrous disk and thereby minimize the danger of rupturing the latter.--

Page 4.

Line 2, cancel "of" and substitute --, such as a relatively hard, high-gloss or water-finish paper provide with a coating of resistant varnish, said disk being--.

Line 3, before "insoluble" insert --water--.

Line 4, after "material" insert --,such as gutta percha,--

Page 5.

Line 26, after "tin" and before the comma insert --or aluminum--.

Page 6.

Line 5, after the period, insert --Aside from the expense of caps provided with foil spots, their use has been extremely limited, due to the fact that foil is not sufficiently resistant to acids and alkalies.

I am aware that it has heretofore been proposed to provide a cap with a center spot of paper, and that this is broadly covered in the patent to McManus, No. 1339,066, granted May 4, 1920. The present invention constitutes an improvement upon the subject matter of said patent.

The use of center spots of paper on a commercial scale has not heretofore been economically practicable for several reasons. First, paper has a tendency to absorb liquids and gases and to impart a taste to and discolor many beverages Moreover, upon absorption of moisture, the paper tends to rupture and expose the cushion material which it overlies. Again, the difficulty of applying a center spot of paper to the cushion disk presents problems altogether different from the use of a facing disk co-extensive with the cushion disk, as for example the facing disclosed in my patent 1,656,614, granted June 17, 1928. A facing which completely covers the cushion disk may be readily united adhesively to the sheet or blank from which the cushion disk is stamped, or in other words, the facing sheet and cushion

sheet are united adhesively, and the laminated disks punched therefrom. But in applying a formed center spot, as distinguished from a sheet, due to the fact that it is necessary to absorb the moisture in the adhesive, and as heretofore explained, during the period of moisture evaporation the spot tends to become displaced. This has presented a problem in large scale production, which manufacturers have not heretofore overcome.

Furthermore, due to the moisture and gas absorbent properties of paper, the exposed edge of the paper spot is of an area which cannot be protected by a facing, such as foil or varnish, since the spot is punched from sheets. This objection I have overcome by using a combination consisting of paper of the character described and a liquid and gas resistant fusible adhesive.

I have found that by using a paper of the character herein described, namely a tough paper having a hard or high-gloss finish, for example, such as is termed a water-finish, the same will not fracture, has an inherent resistance to liquids and gases and serves as an excellent carrier for an exposed or outer facing of varnish and for a backing layer of water-insoluble, heat-fusible and acid and gas-resistant adhesive. I prefer an adhesive having these characteristics and which is also elastic so as to provide an elastic or cushion backing for the varnish layer and the rupturable paper layer.

Extensive commercial use of this new cap has established that it is resistant to acids and alkalies and, therefore, useful in connection with liquids with which a foil spot cannot be employed, and that it is at the same time substantially less expensive than a foil spot cap. Moreover, it does not present the mechanical difficulties which are present in applying a foil center spot. The hard, tough paper serves as an excellent carrier for the varnish film as well as for the gutta percha and instres co-extensive varnish and gutta percha films. The gutta percha serves not only as a medium for uniting the paper and varnish films to the cushion layer, but

constitutes an acid and gas-resistant, water-insoluble, backing layer, thereby preventing moisture, acids or gases which penetrate the varnish film or paper from attaching the cushion layer. Moreover, the use of a hard paper having a water-finish or high-gloss pemits the use of even films of varnish and gutta percha, since the paper does not absorb either the fused gutta percha or the varnish to any appreciable extent. Consequently, it is unnecessary to employ more varnish or thicker gutta percha than is required to cover completely the surfaces of the paper.--

Line 9, cancel "water-leaf finish" and substitute --water-finish, i. e., high gloss finish,--.

Page 10.

Line 5, cancel "e'" and substitute --d'--.

Line 7, after "paper", insert --which has a high gloss or water-finish--.

IN THE CLAIMS

Cancel the claims and substitute:

--28. A bottle closure comprising a metallic shell, a cushion disk in said shell, a facing disk of hard paper having a varnished outer surface, said disk being of smaller diameter than and concentric with said cushion disk, and a stratum of heat-fusible, acid-resistant and water insoluble adhesive material coextensive in area with the facing disk between the latter and the cushion disk and uniting the two disks.

29. A bottle closure comprising a metallic shell, a cushion disk in said shell, a facing disk of hard, high gloss paper having a varnished outer surface, said disk being of smaller diameter than and concentric with said cushion disk, and a stratum of heat-fusible, acid resistant and water insoluble adhesive material coextensive in area with the facing disk between the latter and the cushion disk and uniting the two disks.

30. A bottle closure comprising a metallic shell, a cushion disk in said shell, a facing disk of hard paper having a varnished outer surface, said disk being of smaller diameter than and concentric with said cushion disk, and a stratum of gutta percha coextensive in area with the facing disk between the latter and the cushion disk and adhesively uniting the two disks.

31. A bottle closure comprising a metallic shell, a cushion disk in said shell, a facing disk of hard, high gloss paper having a varnished outer surface, said disk being of smaller diameter than and concentric with said cus ion disk, and a stratum of gutta percha coextensive in area with the facing disk between the latter and the cushion disk and adhesively uniting the two disks.

32. A bottle closure comprising a metallic shell, a cushion disk facing said shell, a facing disk of express paper having a varnished outer surface, said disk being of smaller diameter than and concentric with said cushion disk, and a stratum of gutta percha coextensive in area with the facing disk between the latter and the cushion disk and uniting the two disks.--

33. A bottle closure comprising a metallic shell, a cushion disk facing said shell, a facing disk of water-finish bleached kraft paper having a varnished outer surface, said disk being of smaller diameter than and concentric with said cushion disk, and a stratum of gutta percha coextensive in area with the facing disk between the latter and the cushion disk and uniting the two disks.--

REMARKS

This application, as amended, is presented for consideration, and in addition to the patents of record, applicant's attorneys desire to place of record the following patents:

	1,656,614,	Warth,	Jan.	27, 1928,
	1,339,066,	McManus,	May	4, 1920,
	603,108,	Lindemeyr,	April	26, 1898,
	849,960,	Batchelder,	April	9, 1907,
French	463,971,	Montaner & Co.	of	1914,
French	415,794,	American Cord & Seal Co.,	of	1910,
French	413,841,	Premier Bottle Seal Co. Ltd.	of	1910,
British	26,297,	MacCormick et al.,	of	1909,
British	16,075,	Demuth	of	1914.

In order that the Examiner may have before him a complete statement by one who has been actually engaged in the development of the art, we are filing herewith the applicant's affidavit, supported by other affidavits having to do with the facts of commercial acceptance of the invention which are referred to in the Warth affidavit.

As pointed out in the affidavit, applicant has been engaged in development work in the cap art since 1915, and there is probably no one in the United States, or in fact in any country, who has devoted more time to the technical development in connection with the cap industry. It is believed that, in view of the affidavits, little or no comment is required by counsel upon the prior art. Notwithstanding the general reference in a number of prior patents, including the patent to McManus (1,339,066), to the use of a spot and the vague and general disclosures in the numerous foreign patents, the fact remains that no one contributed the final steps necessary to produce a paper spot cap acceptable to the trade and which could be manufactured on a commercial scale economically, until the applicant devoted his energies to this mark. And when all is said and done, it is impossible to

escape the proposition that even the applicant, although experienced for oven ten (10) years in this particular art when he began development work, and with all the resources and technical assistance of the Crown Cork & Seal Co. available, succeeded in producing the completed article and establishing it on a commercial basis only after a period of three (3) years intensive work. The results of this work speak for themselves. The inadequacy of the aluminum and tin foil center spot caps had been recognized for years. Tin foil spot caps could only be used with waters and alcoholic liquors. They could not be employed to cap materials containing acids or alkalies and salts in more than very dilute solutions. Aluminum spot caps were unfitted for acidulated drinks or alkali and salt containing liquids. The result was that for years users of crown caps had been employing for the capping of acidulated liquids, such as vinegar, cider, ginger ales, vegetable juices and fruit juices, either (a) the very expensive crowns containing natural cork disks, or (b) the somewhat less expensive but more unsatisfactory crowns containing composition disks, i. e., granulated cork and a binder

The fact that the large users of the composition cork disks turned immediately to the crown of the present invention, although from 20 to 25% more expensive than the composition cork disk, is conclusive evidence that applicant's contribution to the art is indeed an important one. Among manufacturers who paid more for this article and in whose business the invention supplanted the crown containing the composition cork disk, are the Hoffman Beverage Company, of Newark, New Jersey, which has used over 50,000 gross of paper spot crowns per year since 1928, The Moxie Company of America, and the May Bottling Company of Baltimore. Over a score of former users of the cheaper composition cork crown, without a facing, could be mentioned all of whom have turned to exclusive use of the paper spot cap described in this application.

Among the large distributors in the United States in whose business this invention has supplanted the natural cork crown which was from 20 to 25% more expensive to both the bottler and the manufacturer, can be mentioned the Clicquot Club Company and the Canada Dry Ginger Ale Company. Both of these companies have used the cap of this invention almost exclusively since 1929.

And the outstanding fact is that, in every instance, the crown was adopted by these companies practically without solicitation and without advertising or sales pressure of any kind. Each company was simply submitted samples of the invention and permitted to test the same over a period of from four (4) to six (6) months. The result was that the invention was adopted by these companies of their own volition as a contribution to the art superior to anything previously available. And in many instances, e. g., Hoffman and Moxie, the article was purchased at a price substantially higher than the price paid for the crowns previously used.

The fact that applicant's invention has made possible a saving of from 20 to 25% in the cost of manufacturing caps suitable for the bottling of high grade ginger ales, such as Clicquot and Canada Dry, is, of itself, strong evidence of invention; particularly in view of the further fact that the manufacturers have quickly adopted the product. But this is not all. Not only may the product be manufactured at a substantial saving in cost, but it is far superior to the more expensive natural cork disk. It does not impart taste to beverages, such as ginger ale, and, therefore, avoids the loss of large volumes of bottled product as frequently occured when crown caps with natural cork disks were used. Consequently, manufacturers were willing to pay a premium of from 20 to 25% for the paper spot cap produced by applicant to supplant the composition cork crown.

These are facts which are fully set forth in the accompanying affidavits, and need no discussion by counsel.

PRIOR ART

Of the prior patents of record, it is thought that none is more pertinent than the patent to McManus (1,339,066). The patentee, McManus, is the President of the Crown Cork & Seal Company, Inc., assignee of the present application. Although his patent discloses broadly the use of a center spot of paper and mentions the paper disc f as one "made of a hard parchment paper, or any other paper so treated as to make it non-absorbent", the affidavit of the applicant shows that, notwithstanding this disclosure, there remained a final contribution to be made to this art in order that paper spot caps for the sealing of many beverages or materials with which metal foil spots could not be used remained to be developed. After a period of experimental work extending over several years, applicant accomplished this result and gave the world the product for which the groundwork had been laid by McManus. But the final steps and those which made the product a commercially useful and successful one were those of the applicant.

Admittedly, applicant's invention is an improvement upon the basic development of McManus; but that does not negative invention. The cases are numerous where an inventor utilizing the broad ideas disclosed by an earlier worker in the art has made the device more successful and established the same on a firm commercial basis.

> "Devices and publications leading up to, but not fully accomplishing, a desired end, do not anticipate an invention which for the first time effectively meets all requirements and successfully accomplishes such end." Truax v. George F. Childs Adjustable Parlor Chair Co., 152 F. 709 (III).

Furthermore, it is true that the materials of applicant's product are old, per se, but it is undeniable that applicant, by a selection of old elements, has produced a new combination and has accomplished results which heretofore had not been ac-

complished. The established commercial success of this invention which has been adopted by practically all leading manufacturers in place of both more expensive and less satisfactory articles theretofore available and in place of less expensive and less satisfactory articles, establishes the invention as well entitled to the liberal treatment held proper by the Supreme Court in Kibel Process Company v. Minn. and Ontario Paper Co., in which Chief Justice Taft, speaking for the Court said:

> "The fact that in a decade of an eager quest for higher speeds this important chain of circumstances had escaped observation, the fact that no one had applied a remedy for the consequent trouble until Kibel, and the final fact that when he made known his discovery, all adopted his remedy, leave no doubt in our minds that what he saw and did was not obvious, and did involve discovery and invention."

When all is said and done, the following facts remain as undisputed.

1. In the face of the disclosures in the prior art no one had provided a cap which would overcome the defects of the expensive natural cork crown disk which alone was useful, although feebly so, in connection with the bottling of acidulated liquids or the defects of the less satisfactory and somewhat less expensive cork composition disks.

2. The industry had for years prior to this invention recognized the limited field of usefulness and the almost prohibitive expense of the metal foil "center spot" caps.

3. Although applicant had before him the disclosures of the prior art, the development of this invention required a long period of experimental work.

4. There is no reference which discloses the combination of elements defined in the claims, and no reference discloses a cap which could be commercially used either in place of or in competition with the cap of applicant's invention.

5. This invention, when offered to the trade by applicant's assignee, the Crown Cork & Seal Company, was immediately adopted, and it supplanted caps previously used for the same purposes. In this field, it was universally found more satisfactory than the more expensive natural cork caps and it was universally adopted as more satisfactory than the less expensive composition cork crowns previously used.

Under these circumstances, we submit that to this case very aptly applies the language of the Supreme Court in Diamond Rubber Company v. Consolidated Rubber Tire Co., 220 U. S. 428. In that case the Court said:

> "Knowledge after the event is always easy, and problems once solved present no difficulties, indeed, may be represented as never having had any, and expert witnesses may be brought forward to show that the new thing which seemed to have eluded the search of the world was always ready at hand and easy to be seen by a merely skillful attention. But the law has other tests of the invention than subtle conjectures of what might have been seen, and yet was not. It regards a change as evidence of novelty, the acceptance and utility of change as a further evidence, even as demonstration."

The fact that this invention has supplanted the prior art devices makes particularly pertinent the statement of the Court of Appeals in in re Thomson C. D. 1906, p. 566:

> "The testimony going to show the practical success of the applicant's combination, the truth of which is substantially conceded, is entitled to material weight. Owing to the very serious difficulties, which appear to have been successfully overcome by the applicant, other electrical train-lighting systems have not gone into general use. The demand for an improved system has been an urgent one for years, and yet no other inventor, or electrical expert, with all the knowledge afforded by prior patents and constructions, has succeeded in devising a system answering this demand. It may be laid down as a general rule, though perhaps not an invariable one, that, if a new combination and arrangement of known elements produced a new and beneficial result never attained before, it is evidence of an invention."

Respectfully,

JJD:U

Attorneys.

Letter #22

IN THE UNITED STATES PATENT OFFICE

Albin H. Warth,

BOTTLE CAPS & METHOD OF MAKING SAME,

Filed May 5, 1929,

Serial No. 360,895

Div. 62.

* * *

CITY OF BALTIMORE)
: ss.
STATE OF MARYLAND)

Albin H. Warth, being first duly sworn, deposes and says:

I am the applicant identified in the above entitled application for patent and am of legal age.

Since approximately 1916, I have been chemical director in charge of the laboratory of the Crown Cork & Seal Co., Inc. and its predecessor Crown Cork & Seal Co. of Baltimore City.

Among my duties have been the testing of materials furnished for the manufacture of crown caps and the development of new materials for the manufacture of caps as well as the development of new types of caps and closures.

Since 1924, I have given particular attention to the development of crown caps of the center spot type. This type of cap consists of a metal shell having the usual cushion disk therein, and the cushion disk is faced by a disk of protecting material united to the cushion disk.

Prior to the development of the invention disclosed in my above entitled application, crown caps consisted of the following types: 133/11

1. Caps having a cushion disk of natural cork.

2. Caps having a cushion disk of granulated cork and a binder.

3. Center spot caps, i. e., embodying a composition or natural cork disk provided with a facing disk of smaller diameter than the cork disk.

The invention of the present application relates to the third type of cap. Before the invention of this application, center spots were formed from only two materials, namely (a) tinfoil and (b) aluminum foil. Spots of metal foil, were the only spot caps commercially available. Although the trade generally was desirous of obtaining "center spot" caps for numerous materials, the use of the tin and aluminum spots was very limited. In the first place, such caps were almost prohibitively expensive, and the handling of metal foil presented many mechanical difficulties due to its flimsy and inelastic character. Moreover, the tin spot had a very limited field for use, being not at all resistant to acids or acidulated liquids, and resistant to only very dilute alkalies and salts. The aluminum spot was also limited in its application, being non-resistant to acids, except weak inorganic acids in solutions not in excess of two-tenths of one per cent, and non-resistant to alkalies or salts in any strength, even as low as one-half of one per cent. Moreover, the aluminum spot tends to decolorize the material within the capped vessel, such as the natural pigments of fruits and vegetable juices.

As a result of the limited applicability of the metal foil center spot caps, it was necessary for bottlers and manufacturers generaly to use caps of very expensive character, and which contained a cushion disk of natural cork. Caps having natural cork cushion disks before the present invention were from twenty to 33 1/100

twenty-five per cent more expensive than even foil center spot caps. Notwithstanding this additional expense, natural cork disks were very unsatisfactory in connection with many materials, particularly those which are highly carbonated, such as gingerale. Yet the principal manufacturers or bottlers of high grade products did not have available for beverages, such as gingerale, or acidulated or alkali containing liquids, any cap more satisfactory than the cap provided with a cushion disk of natural cork. Many bottlers or manufacturers of less prominent brands used for such liquids or beverages, caps having a composition cork disk, i. e. granulated cork and a binder. Such caps were useful where the beverages were used after bottling within a reasonable time, and would retain purity and clarity over relatively short periods such as up to six weeks. These composition cork caps were somewhat less expensive than the center spot caps and were obtainable at from twenty to twenty-five per cent less than the center spot caps.

Generally, therefore, there was available in the trade at the time of the invention of this application for the capping of acidulated, alkali and salt containing liquids, only the natural cork cushion disk caps or the composition cork cushion disk caps. These caps were used, although unsatisfactorily, in connection with fruit juices, vegetable juices, gingerale and on many acidulated beverages for export purposes, although in the latter, due to the necessity for long holds, only the natural cork disks could be used.

Aside from the expensive character of the natural cork caps, the matter of defective caps due to the difficulty of obtaining sufficiently high grade cork, which became obtainable with greater difficulty as the use of crown caps increased, another very serious objection was the inability to avoid imparting of taste to many beverages. This was due to the tanic acid in the cork and

residues of the bleaching materials employed in preparing the cork. I recall one large customer of the Crown Cork & Seal Co. who in one instance had to destroy several thousand dollars worth of gingerale in Baltimore City because the natural cork disks, although the most expensive and unquestionably the best cap available at the time, imparted such an objectionable taste to the gingerale that it could not be sold. This expense had to be borne by the Crown Cork & Seal Co. as the manufacturer of the caps. Faced with this situation, I began to develop a center spot cap which could be used in the capping of fruit juices, vegetable juices, cider, vinegar and generally in th capping of acidulated liquids or materials with which the tin and aluminum center spot cap could not be used.

Although crown caps had been manufactured with a paper facing blank before that date, as disclosed for example in my patent 1,656,614, the manufacture of a crown with a paper "center spot" presented many difficulties which the several years of manufacture of an over-all paper facing did not help to solve.

First, although paper of the center spot cap would appear to be less likely to rupture or fracture because it leaves an exposed surrounding area of the cushion material for direct engagement with the container, I found that the danger of rupture of the center spot was equal to, if not greater than, the danger of rupturing the over-all paper facing disk. This problem of fracture or rupture is one which I had never completely overcome, although the Crown Cork & Seal Co. had for many years manufactured for general use a crown cap having a paper facing completely covering the cushion disk.

Secondly, the center spot of paper presented a free edge of paper which was necessarily uncovered and exposed as dis-

tinguished from the protected edge of the paper facing which completely covered the cushion disk. Extended experiments showed that this exposed edge of the paper absorbed moisture and gases, thereby causing the paper under the high pressures to which it is subjected in the capping operations to rupture; and in many instances, if actual rupture did not take place, the paper became so permeated with gases and moisture as to per it the contents to attack, though the paper, the cushion disk.

Third, in addition to these problems of developing a paper spot which was substantially fracture-proof and impermeable to acids and gases, there was presented the problem of providing a paper spot which would not impart taste to liquids and beverages, particularly of a character in which any foreign taste became immetiately objectionable. This is particularly true with respect to gingerale. There was also the problem of developing, particularly for high pressure beverages or liquids, such as gingerale, a complete or finished center spot of the proper thickness. Although as before explained, crown caps had been provided with a paper facing completely covering the cushion disk, such use over a period of several years contributed little or nothing to the problem of producing a paper center spot. Papers having a thickness of substantially .004 had been used in this connection, but were found entirely unsatisfactory for center spots with highly carbonated or high pressure beverages for the reason that it was found the beverages quickly penetrated this paper. On the other hand, I found that papers having a thickness in excess of .007 were too inflexible and would not produce a satisfactory seal, and it was only after extensive experiments that I determined upon a critical thickness for paper spots, of .005 to .0065, particularly when such spots are intended for capping high pressure liquids.

In addition to the foregoing problems which had to do with a cap for general use, it was necessary to arrive at their solution with due consideration to the question of manufacture, since it was necessary to place an article of this nature upon the market within the range of price of caps already available. Obviously, the manufacturing problems which the article presented, had to be solved without a material increase in the manufacturing cost from the standpoint of manufacturing operations. It was found that the final determination of the character of materials to be used in the manufacture of the paper center spot cap had to take into consideration a change in the established manufacturing methods for center spot caps and to which I refer hereinafter.

Although I was aware that earlier patents had referred to the possible use of a center spot of paper, for example the patent to McManus 1,339,066, granted May 4, 1920, the fact is that there remained to be developed, in view of the problems above mentioned, a paper center spot which would overcome the objections above described an there was required, although I had available the entire laboratory and commercial resources of the largest manufacturers of crown caps in the world, a period of research extending over several years, before I was able to produce a crown cap having a center spot generally useful for the capping of materials for which the tin and aluminum center spots could not be used. The cap produced is disclosed in the above identified application. First, I found after testing dozens of papers, that only two were suitable. These two papers were characterized by (a) hardness and (b) a water-finish or high gloss finish. They were express paper, which is a water-finish paper, and bleached kraft paper having a water-finish. I found that these two papers had inherently a natural

resistance to the absorption of moisture and gases. I further found that they formed an excellent carrier for a coating of protecting or resistant varnish which I had applied to the absorbed surface of the paper.

I further found that even these papers, notwithstanding their natural resistance to liquid and moisture, and, therefore, their reduced tendency to rupture, could not be used satisfactorily with an ordinary adhesive for uniting the same to the cushion disk. Previous to my invention, various types of adhesive had been employed in the cap art, for uniting a facing or spot(metal foil) to a cushion disk. The Crown Cork & Seal Co. had used for many years a mixture of Burgundy pitch and other adhesive materials which constituted an adhesive resistant to liquid. But an adhesive merely moisture resistant was not suitable for a center spot cap. In addition to this adhesive, a large number of other adhesives have been used in the crown cap art, but I found none suitable except the one having the characteristics (a) water-insolubility, (b) heat fusilibity, and (c) acid resistance. The only adhesive available at the time having these characteristics I found to be gutta percha, or a mixture of gutta percha and other materials, making the adhesive essentially gutta percha. I discovered that this particular adhesive had another characteristic which made it of extreme value, namely its inherent elasticity which afforded an elastic cushion or backing for the paper. By employing gutta percha, I found that any moisture or gases which tended to permeate the exposed edge of the center disk of paper, notwithstanding the facing of varnish on the paper, or which permeated through the varnish facing, since no varnish is entirely impermeable, prevented the gases or liquid from attacking the cushion disk. As a consequence, the final article used, after approximately three years of experimental work, was a combination of (a) a varnish facing (b) a hard, tough paper having a high gloss or water-finish, e.g. express paper or water-finish bleached kraft, and (c) an elastic,

water insoluble and acid resistant adhesive, such as gutta percha.

The final development of this spot which proved to be satisfactory in use, presented a number of problems from the standpoint of economical production on a commercial scale. As will be understood, manufacturing plants had already installed machines for the manufacture of center foil spots, and it was necessary, therefore, that I design my cap so that it might be manufactured with existing machinery. Consequently, the selection of these materials was made with concurrent tests as to the responsiveness of the materials to the machinery. For example, I found that the use of a heat fusible adhesive with a paper facing presented manufacturing difficulties, not presented in the manufacture of a foil center spot cap, due to the marked difference in the heat conductivity of the varnished paper as compared to the foil. Nevertheless, I found that by using a gutta percha film, only of sufficient thickness to provide a complete coating for the paper, and employing paper not in excess of .007 and of the character described, it was possible by slightly increasing the heat application in the machines to apply the paper spots to the cushion disks in the same machines previously used for the manufacture of foil spot caps. This matter of manufacturing operation required a considerable period of experiment, and it was not until 1926 that the problem had been completely solved, and large scale production on a commercial basis could be instituted, although two sales in 1927, primarily for experimentation had been made. The commercial results obtained by the invention are a matter of record in the Crown Cork & Seal Co.

BLANK

PAGE

Briefly, they were as follows:-

In 1927, three of the largest manufactures of gingerale in the United States, Cliquot Club Co., Canada Dry Gingerale Co. and Gosman Gingerale Co., were using exclusively crown caps having a cushion disk of natural cork. For these caps the said companies were paying from forty to fifty per cent more than less prominent manufacturers were paying for the only other type of crown then used in connection with gingerale, namely, caps having a cushion disk of composition cork. Among the latter were the Hoffman Beverage Co. of Newark, New Jersey, the May Bottling Co. of Baltimore, Maryland, and the Moxie Company of America, of Boston, Massachusetts.

Within a year, or at the most two years, after this invention had been offered to the trade, the users of natural cork disks such as Canada Dry and Cliquot and Gosman, discarded the natural cork disk for the paper spot disk of the present invention and this type of cap has since been used by these companies almost exclusively.

For the new paper center spot cap, these manufacturers paid from two to three per cent less than the natural cork disk and found the center spot cap much more satisfactory. It represented, therefore, a substantial saving both to the bottler and to the manufacturer.

Not only did the former users of natural cork disks turn to the center spot cap, but the same very largely supplanted the composition cork disk, although the paper center spot cap sold to the users of the composition cork disk at a price forty to fifty per cent higher than they had been previously paying for the composition cork disk. For example, in the year 1927,

Crown Cork and Seal Co. sold exclusively to the Hoffman Beverage Co. of Newark, New Jersey, composition cork disks. In 1928, the Hoffman Beverage Co. purchased over fifty thousand gross of paper spot caps, and has continuously used these caps almost exclusively since that date, paying for the same a considerably higher price than they had previously paid for the composition cork cap. The center spot cap supplanted the composition and natural cork caps substantially throughout the gingerale industry by 1930 and it is now the standard cap for all leading brands of gingerale.

Furthermore, in the capping of highly carbonated beverages which are also acidulated, the paper center spot cap of this application has almost completely supplanted the plain natural cork or composition cork cap.

Whether substituted for the formerly higher price natural cork cap crown, as by Cliquot Club, Canada Dry and Gosman, or for the formerly lower priced composition cork crown, as by Hoffman Beverage Co., Moxie Co. and May Bottling Co. of Baltimore, the paper center spot cap has in every instance been found to be superior to both of the previously used types of crowns.

In the introduction of the paper center spot crown, the Crown Cork and Seal Co. has done virtually no advertising; the article has sold itself. Aside from one or two formal announcements in trade papers that the Crown Cork and Seal Co. was manufacturing paper spot crowns, there has been no advertising of this article. Its adoption by the manufacturers mention above, and numerous others, was the result of merely submitting to each manufacturer a few sample caps with the request that they test the same. They were tested by the Cliquot Club Co. and the Canada Dry Gingerale Co. over a period of six months

before being adopted and were then ordered without further solicitation on the strength of the tests conducted by these Companies. The same statement applies to the adoption of this article by other large manufacturers of acidulated beverages and of other beverages with which the tin spot and aluminum spot cap could not be used.

CITY OF BALTIMORE)
:SS.
STATE OF MARYLAND)

FREDERICK E. FUSTING, being first duly sworn, deposes and says:

That he is Vice-President of the Crown Cork & Seal Company, Inc., having its plant in Baltimore, Maryland, and has been an officer of said company and of its predecessor company, The Crown Cork & Seal Co., of Baltimore City, for over fifteen (15) years.

That he is familiar with the disclosure in the above entitled application which covers the so-called "paper spot" crown first marketed by the Crown Cork & Seal Company, Inc. on a commercial scale in 1928.

That for many years prior to 1925 there had been widely recognized in the crown cap industry a need for a crown cap which would be useful in the bottling of many materials with which "spot crowns" theretofore manufactured could not be employed. Prior to 1925, the only center spot caps available were provided with spots of either tin foil or aluminum foil. These caps could not be employed with acid containing materials, such as fruit juices and ginger ale. For such products it was customary for bottlers to employ crowns having a cushion disc of either (a) natural cork or (b) cork composition material.

The natural cork disc crowns were objectionable because of their very high price and the difficulty in obtaining suit-

able natural cork, particularly for capping high pressure beverages, such as ginger ales. The cork composition disc crowns were even more unsatisfactory.

Prior to 1928, aside from two experimental sales, the Crown Cork & Seal Company had not manufactured a paper spot crown, and to deponent's knowledge no other manufacturer of crown caps had manufactured a cap having a center spot of any material other than foil.

Referring, for example, to the bottlers of ginger ales, such as Canada Dry Ginger Ale and Clicquot Club, these manufacturers prior to 1928 employed crowns having therein discs of natural cork. For these crowns they paid from 26½ to 28½ cents per gross. Yet these crowns, notwithstanding their high price, were not satisfactory. In 1924 the Gosman Ginger Ale Company, of Baltimore, Maryland, met with the loss of a large quantity of bottled ginger ale, due to unsatisfactory crowns of natural cork, and this resulted in a total loss of over Six Thousand Dollars ($6,000.).

Other manufacturers of ginger ale were using crowns having a disc of cork composition and for the same were paying from 17½ to 18½ cents per gross. These crowns were also recognized as not satisfactory. But aside from the natural disc crowns which were considerably more expensive, there were no other crowns on the market even reasonably suitable.

In 1928, when the Crown Cork & Seal Company, Inc., began commercial manufacture of the "paper spot" crown of the above entitled application, over sixty-four thousand (64,000) gross of these crowns were sold. They supplanted in use during 1928 principally the previously used composition cork disc crowns. The users of the new paper spot crown in 1928 paid for the paper spot

crowns 40% more than they had previously paid for the composition cork disc crowns.

In 1929 the Crown Cork & Seal Company, Inc., shipped over one hundred thousand (100,000) gross of paper spot crowns. During that year they supplanted not only the composition cork crowns, but, to a very large extent, the natural cork disc crowns. They were sold to the former users of the natural cork disc crowns at a very slightly lower price than the natural cork disc crowns.

In 1930 the Crown Cork & Seal Company, Inc., sold over two million one hundred thousand (2,100,000) gross. In 1931 the Crown Cork & Seal Company, Inc., sold approximately two million (2,000,000) gross of paper spot crowns.

By 1931, such companies as Canada Dry, Clicquot Club Company, Cosman Ginger Ale and the Moxie Company of America, had adoptedthe paper spot crown almost exclusively in place of the previously used natural cork disc crowns. Other companies, such as the Stroh Products Company, The C. E. May Company and the Hoffman Beverage Company had adopted the same instead of the formerly used composition cork disc crowns and at a price approximately 40% higher.

In other words, the new product had almost completely supplanted the old of natural cork disc and composition cork disc crowns by 1931 in the business of the large bottlers of ginger ale in the United States. The product has been marketed with continued success since its introduction in 1928 and is generally recognized by the trade as far superior of any product previously available.

The increase in sale from less than one hundred thousand (100,000) gross in 1928 to over two million (2,000,000) gross in 1930 was accomplished virtually without advertising, and I can find no record of any advertising expense with reference to

the paper spot crown other than one or two simple announcements in trade journals that the company was making at this price. In practically every instance, there was no particular effort made to sell the paper spot crown. The same was merely submitted to companies such as Canada Dry and the Clicquot Club Company. After months of test, these companies adopted the new product of their own volition in preference to the crown they had previously used.

Further deponent sayeth not.

For Bottle Caps and the Method of Making Same.

MAILED
SEP 29 1933

Additional references made of record:

Warth	1,899,783	Feb. 28, 1933	215-39 (113)
Warth	1,899,784	Feb. 28, 1933	215-39 (114)

Claims 1 to 6 and 13 to 27 are rejected on grounds of disclaimer, based on paper No. 28 filed by applicant in Interference No. 60,931, in which the applicant was involved. It is stated therein:

> "That recently deponent had occasion to examine the proofs available in support of the case for the party Warth in this interference, and that to deponent's surprise it was found that the assignee of the application, Crown Cork & Seal Company of Baltimore, Maryland, had been manufacturing and selling caps having therein (a) a cushion liner (b) a paper facing united to the cushion liner by (c) a waterproof adhesive, and (d) a varnish facing on the paper resistant to acids and alcohol.
>
> "That deponent has found that this material has been manufactured and sold by the Crown Cork & Seal Company, as well as by others in the cap industry almost continuously since 1915 or 1916."

This statement is held to be an admission against interest and is binding against the applicant.

Claims 13 to 27 are further rejected on grounds of estoppel based on paper No. 4, wherein applicant affirms:

> "That the invention was reduced to practice by the manufacture and use of material of the character defined in each count on or about the first day of June, 1915, at Baltimore, Maryland.
>
> "That the material of the character defined in each count has been made in large quantities since June 1, 1915."

[illegible] is rejected as drawn to an obvious

1409

1653

use for the material which applicant, in his preliminary statement referred to above, has declared to have been "reduced to practice by the manufacture and use", etc., and "made in large quantities since 1915".

Claims 1 to 6 and 13 to 27 are further rejected as unpatentable over the above cited patents to Warth on grounds of double patenting. Attention is directed to the claims of the Warth patents in comparison with the claims of the instant case. No patentable distinction is seen in applicant's present claims over the claims in the Warth patents.

UNITED STATES PATENT OFFICE.

GEORGE EMIL STAHL, OF JERSEY CITY, NEW JERSEY.

CLOSURE FOR BOTTLES, JARS, AND OTHER RECEPTACLES.

1,215,737. Specification of Letters Patent. Patented Feb. 13, 1917.

Application filed May 10, 1915. Serial No. 26,978.

To all whom it may concern:

Be it known that I, GEORGE EMIL STAHL, a citizen of the United States, and a resident of Jersey City, in the county of Hudson and State of New Jersey, have invented certain new and useful Improvements in Closures for Bottles, Jars, and other Receptacles, of which the following is a specification.

The invention pertains more particularly to bottle closures of the crown cap type, and resides in a novel lining or interior structure to be applied within the dome of the cap for engagement with the upper edge of the bottle or receptacle to be sealed.

Bottle caps are ordinarily made of sheet tin and contain a rubber ring or a disk of cork or other substance to seal the bottle mouth. These caps have proven inefficient in many instances in respect of their sealing action, particularly in their use on bottles containing beer, due to the necessity of subjecting beer to a high temperature while in the bottles. The pasteurizing of the beer results in an expansion of the gas within the bottles, and considerable difficulty has heretofore been encountered in so sealing the bottles as to prevent the escape of the expanded gas.

In accordance with my invention I provide means for effectually resisting the escape of the expanded gas and maintaining the bottle in a properly sealed condition.

The invention will be fully understood from the detailed description hereinafter presented, reference being had to the accompanying drawings, in which:

Figure 1 is an enlarged central vertical section through a bottle cap having an interior sealing structure embodying my invention;

Fig. 2 is a sectional view on a still larger scale of a portion of the same;

Figs. 3, 4 and 5 are central vertical sections, on an enlarged scale, of the several layers of material employed by me in the formation of the interior structure of the cap, and

Fig. 6 is a bottom view, partly broken away, of the lower laminated disk forming a part of the interior structure of the cap.

In the drawings 10 designates a sheet metal cap of the crown type containing the sealing structure of my invention, this structure comprising, in the preferred embodiment of the invention, a lower laminated sealing disk 11, an upper crown disk 12 and an intermediate ring 13 within which is created within the outline of its inner annular edge and the facing surfaces of the disks 11, 12, a substantial air chamber 14, which it is one of my purposes to create and which is utilized, in accordance with my invention, in effecting and maintaining the proper sealing of the bottle to which the cap may be applied.

The cap 10 is stamped in the usual manner from sheet metal and is commonly designated as a "crown cap," said cap comprising an upper or dome portion 15 and a depending edge flange 16.

The cap 10 may be of any of the usual modified forms of crown caps and is not novel with the exception of its use in connection with the interior or lining structure I provide therein to secure the effectual sealing of the bottle.

The several parts of the interior structure of the cap will preferably vary in thickness and in some respects in character. The disk 12 will preferably be formed from a reasonably thin sheet of paper and will lie directly against the lower surface of the dome of the cap 10. The ring or washer 13 will be formed from jute paper stock or other suitable material and will be considerable thicker than the disk 12 so that a commodious air-chamber 14 may be created within the outlines of said disk or washer 13 and interiorly of the sealing structure of the cap. The disk 11 may be of any suitable material but in the preferred construction is of laminated character and composed of a disk or layer 17 of jute paper stock, a layer of gutta percha, or equivalent substance, 18, adhering to the lower surface of the disk or layer 17, and a very thin layer of paper tissue 19 adhering to the lower surface of the layer of gutta percha 18. The disk 12 and ring or washer 13 are flat and closely engage, at their edges, the inner upper edges of the cap 10. The disk 11 is initially punched flat from a laminated sheet (Fig. 5) and then forced into the inverted cup-shape shown in Fig. 2 whereby the edges of the disk become downwardly flanged, as at 20, and a lower feather edge 21 is formed closely engaging the inner surfaces of the sides of the cap. The disk 11 presents a more extended surface to the cap than would be the case if the flange 20 were omitted and the plain edge of the disk

merely extended out to the side wall of the cap, as will be obvious from an inspection of Fig. 2, and in addition the presence of the flange 20 affords extended surfaces to engage the upper edge or lip of a bottle neck and adds to the effectiveness of the seal.

The layer of gutta percha 18 is impervious to moisture and protects the layers between it and the top of the tin cap from contact with the beer or other liquid, said layer of gutta percha keeping the layer 17, ring or washer 13 and disk 12 dry. The layer of gutta percha 18 also preserves the cushioning character of the sealing structure and in itself contributes to the efficiency of the sealing structure. I also call attention to the fact that in the downward flanging of the edges of the sealing structure the edges of the gutta percha disk 18 become placed in direct contact with the vertical sides of the flange of the cap and create therewith, when the cap is subjected to pressure and the heat of the pasteurizing process, a hermetic seal trapping within the crown of the cap above said disk whatever air there may be therein, so that said air may, in accordance with my invention, act by expansion for effectually maintaining the sealing of the bottle or other receptacle. The downward flanging, as at 20, of the sealing structure arches the lower portion of such structure and when the structure is placed within the cap preparatory to the cap being applied to the bottle, it will maintain its position therein. The thin layer of tissue paper 19 need not cover the whole lower surface of the layer of gutta percha 18 but for convenience of manufacture does do so, and said layer of thin tissue paper 19 is utilized mainly to prevent the heat during the pasteurizing of the beer from so softening the gutta percha 18 as to cause it to unduly adhere to the edges around the mouth of the bottle to which the cap may be applied. The presence of the tissue paper 19 is sufficient to render it certain that the gutta percha will not become unduly affixed to the edges of the mouth of the bottle during the pasteurizing process, and when employed eliminates all danger of the laminated disk 11 adhering to the bottle and leaving the cap 10 when the cap is removed by the usual cap-lifter from the bottle. The disk 11 is punched from a laminated sheet such as I show in Fig. 5 composed of the three layers all closely pressed together and adhering to one another, the paper tissue being about .003 thick and becoming substantially impregnated with the gutta percha and firmly and closely affixed thereto. In Fig. 6 I illustrate the tissue paper layer 19 as having been partly torn away to disclose the gutta percha layer.

The interior or lining structure of the cap is novel and important regardless of the air chamber 14, but the presence of said air chamber adds very greatly to the efficiency of the cap and lining structure and is a characteristic feature of my invention. The presence of the air chamber 14 inclosed within the lining structure and so located as to be concealed, thereby confining the air therein, is of particular importance especially during the pasteurizing process or processes of any nature when the temperature should change the contents of the receptacle, at which time the air within said chamber expands and acts to bind those portions of the disk 11 adjacent to the inner edges of the mouth of the bottle against said edges, while at the same time the air is prevented from escaping from said chamber. All the layers of the lining structure are of yielding material and hence may closely hug the walls of the cap and the surfaces around the mouth of the bottle, whereby the interior chamber 14 becomes hermetically sealed and the body of air therein is adapted to act by expansion for effectually maintaining the sealing of the bottle to which the cap may be applied.

It is well known that very great difficulty is experienced in preventing the escape of gas from a beer or other bottle under varying degrees of temperature and especially during the pasteurization of the liquid or beer in the bottle, and this is in large part due to the different ratios of expansion of the glass and tin, the tin expanding more rapidly than the glass, and the result of these natural conditions is that when the bottle is subjected to heat the tin cap will first expand and tend to loosen from the bottle mouth and permit leakage of gas, and to meet this condition is one of the main purposes of my inclosed air chamber 14. The expansion of the air in the sealed air chamber 14 opposes the pressure of the expanded gas in the bottle neck and augments and maintains the constant pressure of the disk 11 against the lip of the bottle and especially against the inner edges thereof, the expanded air in the lining structure of the cap compensating for the different ratios of expansion between the tin and glass.

A further characteristic feature of my invention is the provision on the disk 11 of the annular depending flange 20 to afford a sealing and cushioning medium extending outwardly over the upper edges of the bottle mouth. It is highly advantageous also that the disk 11 be covered on its lower face with gutta percha or some equivalent impervious substance whose edges are closely bound against the inner sides of the bottle cap 10. The gutta percha layer 18 being adhesive becomes closely incorporated with the paper layer 17 and impregnates the tissue layer 19, and hence the disk 11, while laminated, is substantially in one integral piece. The presence of the gutta percha

layer 18 is also of importance, owing to the nature of the gutta percha itself, being sufficient in thickness to yield to the irregularities in the top of the bottle mouth and to the inner surfaces of the tin cap and being of a clinging nature and of a character not at all prejudicial to the contents of the bottle.

I have hereinbefore described the preferred embodiment of my invention, but I do not wish to be limited to all of the details further than the scope of the appended claims may require. I desire the privilege of the doctrine of equivalency in respect of the materials of which the several parts of the lining structure are made. I therefore do not desire to be confined to the use of jute paper in lieu of paper of some other name, nor do I desire to be limited to the use of gutta percha as distinguished from gum or some equivalent substance or substances which might not be of the nature of gutta percha or gum but equivalent thereto in effecting the sealing of a bottle, protecting the inner layers of the lining structure from the effects of moisture, and coöperating with the expansion of the air in the air chamber 14 in maintaining the bottle sealed and the gases in the bottle properly confined during the pasteurizing or bottling process to which beer or other liquids may be subjected.

In the drawings I illustrate a single air chamber 14, but if this air chamber were subdivided by partitions into a plurality of air chambers I would regard the then plural number of air chambers as the air chamber of my invention.

What I claim as my invention and desire to secure by Letters-Patent, is:

1. A closure for bottles and the like, comprising a sheet metal cap of the crown type having a dome and a depending edge flange, and a sealing structure within said cap comprising a yielding body to engage at its outer edges the side walls of the cap and the edge of the bottle mouth and confining air to act by expansion for effectually maintaining the sealing of the bottle, said sealing structure in its lower peripheral part being initially flanged downwardly and closely engaging the flange of the cap and also being impervious to moisture and of a character to adhere at its edges to the said flange so as to make a hermetic seal trapping said air.

2. A closure for bottles and the like, comprising a sheet metal cap of the crown type having a dome and a depending edge flange, and a sealing structure within said cap comprising a yielding body to engage at its outer edges the side walls of the cap and the edge of the bottle mouth, said sealing structure having an upper cushioning portion and a lower portion initially flanged downwardly along its peripheral edges and closely engaging the flange of the cap and having a lower coating of material rendering the sealing structure impervious to moisture and of a character to adhere at its edges to the said flange, so as to form a circumferential hermetic seal.

3. A closure for bottles and the like, comprising a sheet metal cap of the crown type having a dome and a depending edge flange, and a sealing structure within said cap comprising a yielding body to engage at its outer edges the side walls of the cap and the edge of the bottle mouth, said sealing structure having an upper cushioning portion and a lower portion initially flanged downwardly along its peripheral edges and closely engaging the flange of the cap and having a lower coating of gutta percha rendering the sealing structure impervious to moisture and of a character to adhere at its edges to the said flange, so as to form a circumferential hermetic seal.

4. A closure for bottles and the like, comprising a sheet metal cap of the crown type having a dome and a depending edge flange, and a sealing structure within said cap comprising a yielding body to engage at its outer edges the side walls of the cap and the edge of the bottle mouth, said sealing structure having an upper cushioning portion and a lower portion initially flanged downwardly along its peripheral edges and closely engaging the flange of the cap and having a lower coating of gutta percha rendering the sealing structure impervious to moisture and of a character to adhere at its edges to the said flange, so as to form a circumferential hermetic seal, said gutta percha having on its lower surface a thin tissue to prevent it from adhering so tightly to the bottle mouth as to pull the sealing structure from the cap on the uncapping of the bottle.

5. A closure for bottles and the like, comprising a sheet metal cap of the crown type having a dome and a depending edge flange, and a sealing structure within said cap comprising a yielding body to engage at its outer edges the side walls of the cap and the edge of the bottle mouth and containing a definite air chamber in which a body of air is effectually sealed to act by expansion for maintaining the sealing of the bottle, said sealing structure having at its lower part a layer of gutta percha closely bound thereto and thereby rendering the structure impervious to moisture and to the entrance of gas from the bottle, and said layer of gutta percha being in engagement with the flange on the cap so as to effect a circumferential seal therewith and also adapted to seal along the bottle mouth, whereby the bottle becomes sealed and the air in said chamber becomes effectually confined.

6. A closure for bottles and the like, comprising a metal cap of the crown type having a dome and a depending edge flange, and a sealing structure therein comprising a lower cushioning disk of paper having on its lower side a substance rendering it non-absorbent and non-porous and above said disk a ring of paper within whose interior outline is formed an air chamber, said sealing structure being adapted to engage at its outer edges the side walls of the cap and the edge of the bottle mouth, and said disk initially having a depending edge flange to engage the inner side walls of the cap and the outer edges of the bottle mouth and said air chamber being hermetically sealed to confine therein a body of air to act by expansion for effectually maintaining the sealing of the bottle.

7. A closure for bottles and the like, comprising a sheet metal cap of the crown type having a dome and an edge flange to be crimped on the bottle, and a sealing structure within said cap comprising a yielding body to engage at its outer edge the side walls of the cap and the edge of the bottle mouth and consisting of a lower layer, an intermediate ring layer and a disk top layer, said intermediate layer being open interiorly to form an air chamber between its inner edges and the said lower and upper layers and said layers being closely bound together and protected against the effects of moisture, whereby said air chamber becomes permanently maintained and confines a body of air to act by expansion against said yielding body for effectually maintaining the sealing of the bottle, and said sealing structure being formed along its outer edges with a depending flange closely engaging the inner sides of the cap and adapted to engage the outer side edges of the mouth of the bottle.

8. A closure for bottles and the like, comprising a sheet metal cap of the crown type having a dome and an edge flange to be crimped on the bottle, and a sealing structure within said cap comprising a yielding body to engage at its outer edge the side walls of the cap and the edge of the bottle mouth and consisting of a lower paper layer having bound on its lower surface a covering of gutta percha, an intermediate ring layer and a disk top layer, said intermediate layer being open interiorly to form an air chamber between its inner edges and the said lower and upper layers and said layers being closely bound together, whereby said air chamber becomes permanently maintained and confines a body of air to act by expansion against said yielding body for effectually maintaining the sealing of the bottle, said lower layer at its outer edges being formed with a depending flange closely engaging the inner sides of the cap and adapted to engage the outer side edges of the mouth of the bottle.

Signed at New York city, in the county of New York and State of New York, this 7th day of May, A. D. 1915.

GEORGE EMIL STAHL.

UNITED STATES PATENT OFFICE

LOUVERN G. LANGE, OF PASSAIC, NEW JERSEY

COMPOSITE MATERIAL FOR CONTAINERS

Application filed February 3, 1930. Serial No. 425,600.

This invention relates to composite material for use in the manufacture of containers and more particularly to a composite material especially adapted to the purpose of providing a liner for bottle caps and the covers of containers in general.

This application may be considered as a continuation in part of my application, Serial Number 375,882 and Patent No. 1,758,610, both filed July 3, 1929.

In order that my invention may be clearly understood I will explain its application to the problem of providing an improved liner for bottle caps, jar covers and the like, although it will be understood that my invention is not limited to such applications thereof.

It has been common practice in the past to provide metal bottle caps, jar covers and the like with cork inserts which come directly in contact with the top of the bottle, or other receptacle. These cork inserts or discs are clamped in position by any suitable means, such as the crimped edge of the ordinary bottle cap, and the insert is supposed to form a seal for the contents of the container. The use of natural cork for this purpose is not very satisfactory because the natural cork contains imperfections which may render an insert made from this material incapable of forming a complete seal for the container. Composition cork inserts have been employed, such inserts comprising comminuted cork and a suitable binder. Such composition inserts, or liners, are more dense and uniform than such liners made from the natural product but they are still unsatisfactory for many purposes because of the fact that the binder of the composition is attacked by many solvents and this results in disintegration of the material which is supposed to form the seal for the container.

In the production of inserts, or liners, for bottle caps, jar covers and the like it is desirable to use some material such as cork, or composition cork, which is resilient and thus capable of conforming to the configuration of the top of the container. At the same time the materials just mentioned are objectionable for the reasons pointed out above and it is an object of the present invention to provide a composite material suitable for use as liner, or insert material, as well as for other purposes and which is not open to the objections pointed out in connection with the materials discussed above. Natural cork, composition cork and other fibrous resilient materials may be used in accomplishing the objects of my invention but these materials are not used alone, or merely protected by a single coating of material which is supposed to improve their characteristics as has been suggested heretofore.

According to my invention as applied to the making of bottle cap liners and the like I provide some preferably resilient fibrous material, such as cork, composition cork, pulp board, news board, or gray felt and to this material I apply protective layers of a waterproof adhesive and an insoluble varnish. The adhesive and varnish may be carried by a suitable medium, such as cellulose material in sheet form, for example, paper, or the like. I have found that paper is quite satisfactory as a carrying medium and I prefer to employ thoroughly sized paper which has been thoroughly calendered to provide hard surfaces. To one surface of the paper, or other carrying medium, I apply in any suitable manner a film of what I call insoluble varnish. In general it may be stated that by insoluble varnish is meant a varnish which is insoluble, or inert to such solvents as alcohol, acetic acid, citric acid and carbonic acid. Such varnish, although insoluble in and impervious to alcohol and acids of the character described, nevertheless absorbs some moisture and permits some moisture to pass through a film of this varnish. Accordingly, I employ a film of waterproof adhesive and this is employed in such a manner that it is protected from the action of alcohol and other solvents of the character indicated above which would otherwise destroy the adhesive. As indicated above I may apply to one surface of the sheet of paper, or the like, a film of insoluble varnish. To the other surface I apply a film of waterproof adhesive, such as gutta-percha, or similar rubber-like material. This adhesive may be used as a means

for bonding the sheet of paper, or the like, to a base material, preferably resilient in character, such as cork, pulp board or felt. This composite material may be cut into suitable form for application to bottle caps, jar covers and the like, or, if desired, the material may in a sense be assembled within the container cover. For example, the paper may be coated, or otherwise provided with films of varnish and adhesive. The resilient material may be inserted in the container cover and thereafter the varnished and adhesive coated paper may be applied to the fibrous material within the container cover or cap.

I prefer to employ a varnish which comprises a resin which is resistant to alcohol, acetic acid, carbonic acid and the like and an oil which is resistant to these materials. It will be understood that the varnished surface of the paper, or other carrying medium, is exposed to the contents of the bottle, or other container. The films of varnish and adhesive cover the underlying resilient material and together form a complete seal for the container, which is impervious to moisture and inert to the action of such ingredients as may constitute the contents of the container. The adhesive is protected by the varnish and, while the varnish alone is incapable of preventing the escape of moisture, yet this function is performed in a satisfactory manner by the adhesive which remains intact because of the presence of the protective film of varnish.

It will be understood that my invention is particularly suitable for use in the manufacture of containers for beverages, food products and pharmaceutical preparations, many of which contain alcohol, or acids of the character indicated above, which would attack and destroy the ordinary varnish films heretofore proposed as a means for sealing the surface of cork, or other inserts used in container covers.

The various objects and advantages of my invention will be more apparent upon considering the following detailed description which is to be considered in conjunction with the accompanying drawings wherein:

Fig. 1 is a plan view of a strip of composite material embodying my invention;

Fig. 2 is an enlarged plan view of a disc cut from the strip illustrated in Fig. 1;

Fig. 3 is an enlarged elevation of the disc shown in Fig. 2 and

Fig. 4 is a greatly enlarged fragmentary section view of a portion of the disc illustrated in Figs. 2 and 3.

In the accompanying drawings I have illustrated one embodiment of my invention as applied to the production of liners or inserts for bottle caps, jar covers and the like. It will be understood that my invention may be applied to other purposes however.

Referring to Fig. 1 of the accompanying drawing I have shown a strip of composite material embodying my invention, this strip comprising a base layer of material 1 preferably resilient in character and a superimposed composite layer 2 adhering to the base layer. In Fig. 1 the composite material is shown in strip form from which blanks may be cut in any desired shape to fit bottle caps, jar covers and the like, or for other purposes.

Fig. 2 shows in enlarged form a circular disc cut from the strip illustrated in Fig. 1. From this enlarged view it appears that the composite layer 2 supported by the base 1 comprises a carrying medium 3 in the form of a sheet of paper having on its upper surface a film 4 of insoluble varnish and on its lower surface a film of waterproof adhesive 5.

It will be understood that when the improved composite material is used as an insert or liner for bottle caps, jar covers and the like the base material 1 comes in contact with the inside of the cap or cover and the varnished film is exposed to the contents of the container. The film of varnish is highly resistant to and impervious to solvents, such as alcohol, acetic acid, citric acid and carbonic acid, or in other words the varnished film may be said to be insoluble. The adhesive 5, while not necessarily insoluble in alcohol and acids of the character described, is nevertheless impervious to moisture and effectively prevents any moisture which may pass through the film of varnish from entering the underlying base material 1. The layer of paper, or the like, disposed between the films of varnish and adhesive serves, not only as a carrier for these films, but also as a means for strengthening and reinforcing the composite material to prevent accidental injury to the underlying adhesive film. The combination of varnish and adhesive films according to this invention entirely prevents the escape of moisture through the material, which would have a tendency to cause the underlying base material to decompose or mold and this result is accomplished by employing a varnish which is impervious to solvents of the character indicated for protecting a layer or film of adhesive which is effective in preventing the escape of moisture from the container.

The layer of paper, or other cellulose material, illustrated at 3 in the figures of the accompanying drawing is preferably hard surfaced. Where I employ paper I prefer to use paper which has been heavily sized and well calendered to provide glossy surfaces. My reason for preferring this material is that by its use the penetration of the varnish and adhesive into the paper is largely prevented and the varnish and adhesive remain on the surface forming substantially continuous films.

The adhesive material 5 is preferably

gutta-percha, or other rubberlike composition. I prefer to employ a composition comprising gutta-percha, for this material can be softened by heat and by heating the paper carrying the film of adhesive and by heating the underlying material, the layers of material may be effectively united by pressure. Gutta-percha is ordinarily combined with other gums or substances in order to impart to the gutta-percha desirable properties. Balata gums and various other resins are frequently used for this purpose. It will be understood that the term gutta-percha as used herein is intended to describe an adhesive material composed entirely, or only in part, of gutta-percha for various ingredients may be combined with the gutta-percha to improve its characteristics for certain purposes. Gutta-percha in strip form may be applied to the paper 3 in any suitable manner, or the gutta-percha adhesive may be dissolved in a suitable solvent and applied to the paper 3 in liquid form. Where the product is to be used under conditions such that relatively high atmospheric temperatures prevail it is desirable to incorporate with the gutta-percha materials which have a tendency to harden the same and prevent it from melting or softening at elevated atmospheric temperatures. On the other hand where the material is to be used under conditions where low temperatures prevail the gutta-percha composition may be altered accordingly to provide an adhesive which is not unduly brittle at the prevailing low temperatures.

Gutta-percha is especially suitable for accomplishing the objects of my invention for it is waterproof and when combined with a film of varnish as contemplated by my invention a composite material impervious to moisture is formed.

Where the gutta-percha is applied to the paper in liquid form the gutta-percha adhesive may be first dissolved in an appropriate volatile solvent, such as highly refined gasoline, naphtha, toluene, benzene or xylene. The solution may be heated until the mass thickens and it may be applied in the thickened state to the back of paper previously varnished and the remaining volatile solvent permitted to avaporate.

The varnished film 4 covering one surface of the paper, or other cellulose material 3, is preferably the dried residue of a varnish containing a resin which is resistant to alcohol and the acids above indicated and an oil the dried film of which is resistant to these solvents. Various gums or resins are available for this purpose including certain natural gums and at least one synthetic gum. Of the natural gums Zanzibar, Madagascar, and esterized manila gums give the best results. All of these natural gums which are insoluble in alcohol, and black damar, elastica (dry rubber resin) and certain grades of copal, fuse with difficulty in the oils. Esterized manila however fuses more readily than the others. None of these gums however fuse with the oils as readily as the synthetic cumar gum, nor are the finished films as resistant to the action of solvents as is the cumar gum. Cumar gum (manufactured by the Barrett Company) is soluble in the hot oils of the varnish without any preparatory treatment. Cumar gum may be compounded largely with certain of the oils which are resistant to alcohol, such for example as China wood oil, and it has been found that with such a combination it is possible to add small amounts of oil, such as linseed oil, which is soluble in alcohol, and this without destroying the alcohol resisting properties of the varnish. In making the varnish one or more of the usual driers may be added in appropriate amounts to give a coating of the desired consistency and any volatile thinner in which the constituents of the varnish are soluble may be employed. For this purpose a hydrocarbon thinner, such as high test kerosene, is suitable.

Various oils may be used to dissolve the cumar gum. The following example is given as a representative varnish composition which may be regarded as insoluble in alcohol and in acids of the character indicated above:—150 pounds cumar gum, 50 gallons China wood oil, 5 gallons linseed oil, 5 gallons perilla oil, 18 pounds precipitated manganese resinate, 10 pounds cobalt linolate, 5 pounds full bleached paraffin.

This varnish may be thinned down hot with high test kerosene, or any other appropriate volatile solvent. This example is used merely as an illustration of one type of varnish which is suitable for carrying out my invention. Such a varnish successfully withstands the corrosive or solvent action of chemicals such as alcohol, acetice acid and citric acid or the like customarily encountered in beverages, food products, pharmaceutical preparations and cosmetics.

A departure from the formula given above may be made without sacrificing all of the advantages of my invention. The quantity of linseed oil may be further reduced, or the paraffin may be reduced or eliminated where special conditions of use indicate this to be desirable. Any of the ingredients may be used, in different amounts, or eliminated without departing from the spirit of the invention wherever conditions of use require such modification of a combination of ingredients. I prefer to employ a gum or resin which is insoluble in alcohol but soluble in hot oil in the nature of China wood oil.

After the varnish is applied to the paper it is preferably baked to harden the varnish film and increase its resistance to the action of chemicals. It is quite satisfactory to bake the varnished paper at a temperature of ap-

proximately 300° F. for about an hour. The adhesive coating may be applied to the paper after the baking operation has been completed.

It is to be understood that my invention is not limited to the particular embodiments illustrated and described but includes such modifications thereof as fall within the scope of the appended claims.

I claim:

1. A composite material of the character described comprising a layer of sheet material, an insoluble film of varnish adhering to one surface of said layer of sheet material, a layer of resilient material, and a waterproof adhesive bonding said resilient material to the other surface of said layer of sheet material, whereby the adhesive is protected from the action of solvents by the film of varnish and a composite material impervious to moisture is formed.

2. A composite material of the character described comprising a layer of sheet material, an alcohol resistant film of varnish adhering to one surface of said layer of sheet material, a layer of resilient material and a waterproof adhesive bonding said resilient material to the other surface of said layer of sheet material.

3. A composite material of the character described comprising a layer of sized paper, an insoluble film of varnish adhering to one surface of the paper, a layer of resilient material, and a film of waterproof adhesive bonding said resilient material to the other surface of the paper, whereby the adhesive is protected from the action of solvents by the film of varnish and a composite material impervious to moisture is formed.

4. A composite material of the character described comprising a layer of sheet material, an insoluble film of varnish adhering to one surface of said layer of sheet material, a layer of resilient material and a waterproof adhesive bonding said resilient material to the other surface of said layer of sheet material, said insoluble film of varnish consisting of the dried residue of a varnish comprising a gum insoluble in alcohol and an oil the dried film of which is resistant to alcohol.

5. A composite material of the character described comprising a layer of sheet material, an insoluble film of varnish adhering to one surface of said layer of sheet material, a layer of resilient material and a waterproof adhesive bonding said resilient material to the other surface of said layer of sheet material, said insoluble film of varnish consisting of the dried residue of a varnish comprising cumar gum and an oil the dried film of which is resistant to alcohol.

6. A composite material of the character described comprising a layer of sheet material, an insoluble film of varnish adhering to one surface of said layer of sheet material, a layer of resilient material and a waterproof adhesive bonding said resilient material to the other surface of said layer of sheet material, said insoluble film of varnish consisting of the dried residue of a varnish comprising cumar gum and China wood oil.

7. A composite material of the character described comprising a layer of sheet material, an insoluble film of varnish adhering to one surface of said layer of sheet material, a layer of resilient material, and a waterproof adhesive bonding said resilient material to the other surface of said layer of sheet material, said insoluble film of varnish consisting of the dried residue of a varnish comprising cumar gum, China wood oil and linseed oil in the approximate proportions of 150 pounds of cumar gum to 50 gallons of China wood oil and approximately 5 gallons of linseed oil.

8. A composite material of the character described comprising a layer of sheet material, an insoluble film of varnish adhering to one surface of said layer of sheet material, a layer of resilient material and a waterproof adhesive comprising gutta-percha bonding said layer of resilient material to the other surface of said sheet material, whereby the adhesive is protected from the action of solvents by the film of varnish and a composite material impervious to moisture is formed.

9. A composite material of the character described comprising a layer of sheet material, an insoluble film of varnish adhering to one surface of said layer of sheet material, a layer of fibrous material, and a waterproof adhesive bonding said fibrous material to the other surface of said layer of sheet material, whereby the adhesive is protected from the action of solvents by the film of varnish and a composite material impervious to moisture is formed.

In testimony whereof I affix my signature.

UNITED STATES PATENT OFFICE.

EDWARD W. HANAUER, OF PHILADELPHIA, PENNSYLVANIA, ASSIGNOR OF ONE-HALF TO GERSON DANNENBERG, OF SAME PLACE.

STAY FOR TROUSERS.

SPECIFICATION forming part of Letters Patent No. 671,191, dated April 2, 1901.

Application filed September 8, 1900. Serial No. 29,360. (No specimens.)

To all whom it may concern:

Be it known that I, EDWARD W. HANAUER, a citizen of the United States, residing in the city and county of Philadelphia, State of Pennsylvania, have invented a new and useful Improvement in Stays for Trousers, of which the following is a specification.

My invention consists of an improvement in stays for trousers, as will be hereinafter fully described and claimed.

Figure 1 represents a plan view of a blank from which the stay embodying my invention is formed, illustrating also the manner of cutting the same. Fig. 2 represents a plan of the said bottom stay. Fig. 3 represents a fragmentary view of the bottom portion of the trousers. Fig. 4 represents a sectional view of the same, taken on the line *x x*.

Similar letters of reference indicate corresponding parts in the figures.

Referring to the drawings, A designates a portion of a leg of a pair of trousers, and B the bottom turn-up thereof.

C designates a stay formed, as usual, of a gummy piece that is inserted between the bottom portion and the turn-up of the trousers and which by adhering thereto holds the turn-up in position, thus obviating sewing the same. This gummy piece may consist of a piece of gutta-percha, rubber, canvas, or other material or fabric and is caused to adhere to the trousers and turn-up usually by the application of a hot iron to the outside thereof after the stay has been inserted therebetween. The upper edge portion of said piece is continuous, as at C', and adapted to extend along the upper edge of the turn-up B and the lower portion of said stay is serrated or broken, forming a series of depending tongues D, which are separated by the intervening spaces E.

It will be seen that when the stay is secured to the turn-up and the adjacent portion of the leg of the trousers said turn-up is strengthened and sustained, as is also the adjacent bottom portion of the leg of the trousers, but owing to the spaces E or breaks in the lengths of the stay the bottom of the trousers is rendered somewhat pliable, avoiding a stiff appearance and caused to hang naturally and softly over the shoes of the wearer, while also preventing rapid wearing out of the lower edge of the leg. There is also economy in the manufacture of the stays in that a serrated or serpentine cut is made in a strip of material and the edges of said cut are common to two stays, as shown in Fig. 1.

By this method of manufacture I am enabled to make a pair of stays from, say, a two-inch strip of material, each member of the pair being an inch and a half wide, there being thus much saving in material and expense.

Having thus described my invention, what I claim as new, and desire to secure by Letters Patent, is—

A garment provided with a bottom stay consisting of a piece of gummy material having a broken lower edge, said stay being situated between the bottom portion of the garment and the turn-up thereof and adhesively secured to the inner faces thereof.

EDWARD W. HANAUER.

PETITION A 2962

APR-4 33 720371 A-Check — 50.00

TO THE COMMISSIONER OF PATENTS:

Your petitioner Albin H. Warth,

residing at Baltimore,

~~Baltimore County~~ State of Maryland,

whose Post Office address is C/o Crown Cork & Seal Company, Inc., Baltimore, Maryland,

prays that Letters Patent may be granted to him for improvements in METHOD OF MANUFACTURING BOTTLE CAPS AND APPARATUS THEREFOR, as set forth in the annexed specification.

And he hereby appoints Arlon W. Cushman, ~~Arthur Kirkpatrick~~ John J. Darby and William M. Cushman (constituting the firm of Cushman, ~~Kirkpatrick~~ Darby & Cushman, Washington, D. C., Registration No. 7196) and each of them, his Attorneys, with full power of substitution and revocation, to prosecute this application, to make alterations and amendments therein, to sign the drawings, to receive the Patent, and to transact all business in the Patent Office connected therewith.

Albin H. Warth

(Inventor's Full Name)

SPECIFICATION

TO ALL WHOM IT MAY CONCERN:

BE IT KNOWN, that I, Albin H. Warth,

residing at Baltimore,

~~Baltimore County~~ State of Maryland,

have invented certain new and useful improvements in

per B3 METHOD OF MANUFACTURING BOTTLE CAPS ~~AND APPARATUS THEREFOR~~

and I do hereby declare the following to be a full, clear and exact description of the invention, such as will enable others skilled in the art to which it appertains, to make and use the same:

This invention relates to a method of producing closures of the type in which a sealing disk has a facing. This type of closure is characterized by the provision, upon the interior cushion or sealing disc, of a facing or spot having a surface which protects the cushion material from the liquids and gases.

This application is a division of my copending application, Serial No. 494,201, filed November 7, 1930, and the latter is a division of my application, Serial No. 159,743, filed January 7, 1927, now Patent No. 1,788,280, granted January 6, 1931.

Closures of the well known crown cork type comprise a metal shell having a skirt and a resilient sealing disk, usually made of cork. For some uses, the sealing disks are given a facing, e. g., tin foil, or aluminum foil, these materials or other materials of protective character being suitable to provide a non-absorbent, gas impervious, and acid resistant facing. Ordinarily this facing is of smaller diameter than the cork disks and such crowns are known in the trade as "spot center crowns".

These spot center crowns have been produced in various ways. According to one method a slot or groove is cut in the cork disk

and the spot is given an inturned rim which is inserted in the slot. This method is objectionable because of its expense and because the tin foil spots are apt to drop out. According to another method the spots are pasted to the cork disks by a casein paste or a glue. In crowns so made the spots tend to loosen as the paste or glue is attacked by the packaged liquids. Furthermore, such method involves difficulties in handling and in applying the paste or glue. According to still another method, the spots are secured by an underlying and separately formed and deposited tissue of gutta percha or coated paper. In crowns so made, like objections are met with. For example, one difficulty in applying disks made from separate strips, such as gas and acid resistant material and the adhesive tissue strips, has arisen from the necessity for feeding the two strips to the punching and assembly machine. There is not only difficulty in feeding the strips, but in cutting the separate tissue strip with a clean, sharp edge so as to insure the binding stratum of adhesive being coextensive in area with the disc of liquid resistant material. As will be understood, the adhesive stratum is intended to act not only as a cement, but also as a waterproof, non-absorbent, gas impervious medium for avoiding the possibility of the contents of a bottle getting between the facing disk and the material of the cap, either the metal shelf itself or a cushion disk of cork or composition cork.

Furthermore, when using superimposed strips of the facing material and of adhesive tissue, it was essential, to bond the adhesive tissue to both the material of the cushion disc in the cap and the facing material.

In preparing the rolls of facing material and adhesive tissue, the practice usually followed was to form a roll of the tissue in strips of the desired width, and to unwind this roll and a roll of the facing material while feeding the two

strips one over the other into the disk forming and assembling machine. This is a troublesome and expensive operation, because of the frequent breakage of the adhesive tissue and the necessity for using fairly heavy tissue to minimize this tendency. This is due partly to the fact that the facing material was substantially non-elastic, while the adhesive tissue possessed a certain degree of elasticity, thus introducing a factor of difficulty in securing a uniform paying of both the facing strip and the gutta percha tissue strip.

34

It is desirable, in the use of facing disks of the character above referred to, that the adhesive stratum be as thin as possible, and yet be continuous throughout the entire area of the facing disk, and particularly that it be uninterrupted about the edge of this disk, since at this point the disk should be firmly bonded so as to effectively seal the joint about the edge of the facing disk. When cutting and applying the disks of material and adhesive, there is no means of ascertaining whether the desired conditions are present in the completed cap. Consequently, there is always likelihood of imperfectly faced caps being produced.

With the above conditions in mind, I have provided material, in strip form, for facing bottle caps, in which one surface of the strip is provided with a firmly adherent, continuous thin facing of adhesive, thus avoiding all necessity for assembling strips of facing material and of adhesive tissue preparatory to their use in the bottle cap facing machine, and all of the disadvantages growing out of this practice.

In the strip material of my invention, a very thin stratum of adhesive is evenly distributed upon one face of a strip of facing material. The adhesive is not only firmly bonded to this material, but has a smooth surface finish of sufficient thickness to form the desired firm bond between a disk cut from the strip and the material of the cap to which such disk is cemented.

Furthermore, adhesive tissue must be of a thickness to have sufficient inherent strength to permit of its being stripped from a roll in a mill for working same, and to admit of its being cut to the desired width and to be handled in the winding and the disk applying machines, and during the process of its production it has more or less of a longitudinally extending grain, as distinguished from its normal granular formation.

In the application of heat, when bonding the facing material to the cap, when utilizing adhesive tissue, a tendency of the adhesive is to break up into slightly isolated, small globules, thus interrupting the continuity of the bonding stratum. Whether this is due to irregularities in the surface of the facing strip, or to a shrinkage of the adhesive tissue when fused, I have been unable to determine. In the strip of my invention, however, the adhesive is thoroughly distributed throughout one face of the facing material, and the above conditions do not develop in the subsequent handling of the strips.

It is an object of the present invention to provide a method of producing spot center crowns such that the spots may be rapidly and economically secured to the sealing disks and such that they are firmly secured and not liable to become loosened in use.

With these general objects in view, the invention consists in the method which will be first described and then more particularly pointed out in the claim.

According to the method of the present invention, the strip material, such as metal foil, is coated with a substance that is devoid of tackiness when dry and has adhesive qualities when soft. In carrying out the method according to what is considered the best practice, the adhesive substance is such that it can be applied cold, i. e., at room temperatures, and is insoluble in cold water. While various materials may be used,

I have found a suitable adhesive in a solution of damar resin and rosin in mineral spirit or turpentine, to which is added 5% or less of a vegetable oil, such as soya bean or chinawood oil. The damar gum and rosin may be in the proportion of 35% to the whole. The adhesive may have a drier of lead resinate or the like in a proportion of 2% or less. Another example of a suitable gum type of adhesive is gutta percha or a gutta percha containing compound which have characteristics similar to the composition previously described. Among such characteristics are substantially non-tackiness or adherence at room temperature a high degree of flexibility, insolubility in and imperviousness to moisture or water, acid resistance and heat fusibility, i. e., adapted to be brought to a tacky state by the mere application of heat and without the use of moisture. Such an adhesive is specified in my copending application, Serial No. 414,614, filed December 17, 1929, now Patent No. 1,899,782, granted February 28, 1933.

An adhesive of this character provides a highly flexible adhesive layer continuously united with the facing material. Moreover, such an adhesive is highly resistant to the acids and alkalies ordinarily present in liquids which are to be capped. This is highly important in the manufacture of spot caps, since the liquids attack the adhesive around the edge of the spot. An adhesive of this character, which is not only waterproof, but resistant to acids and alkalies as well, maintains a firm adherent union of the facing or spot material with the cork disk. Due to its flexible character, it will not crack, and, therefore, it constitutes a flexible backing for the spot material.

While the coating may be applied to the material in various ways, it is conveniently applied in fluid form and cold to a strip of foil from which the spots are to be cut. So far as the method of producing the strip is concerned, it is such

that the effective distribution of the adhesive throughout the entire area of the facing material is assured, and this condition cannot be disturbed as a result of the cutting of disks from this material when in strip form. Furthermore, the adhesive surface may be thoroughly inspected while producing the strip material, so that any imperfect product may be discarded before it reaches the disk applying machine. In this connection it is noted that the spots may be conveniently assembled by feeding a strip of material over successive crown corks and cutting out a disk which is deposited on a cork, such assembling machinery being known in the art.

After the coating is applied to the material, it is dried. While this may be effected by air drying at room temperatures, it is more rapidly accomplished at a temperature of about 300°F. maintained for about three minutes. When dried the coating is devoid of tackiness so that the metal foil may be handled without difficulty or trouble. This is particularly advantageous when the metal foil is to be fed in strips because the application of the adhesive is carried out independently of the assembling steps. Moreover, the coating gives the thin metal foil more or less body, which facilitates feeding and cutting.

Since the adhesive is applied directly to the surface of the facing or spot material and firmly bonded thereto, there is no likelihood of difficulties arising as a result of separation of the adhesive from the facing strip during the spot forming operation, either as a result of poor adherence or from suction or otherwise, such as frequently occurs when using superimposed strips of facing material and of adhesive tissue. Moreover, in handling this material the adhesive stratum is incapable of stretch or distortion relative to the spot strip as frequently occurs in the handling of separate strip of adhesive

tissue and facing material where any stretch or distortion of the adhesive stratum results in a defective cap and when the stre. is extreme, tearing of the adhesive tissue makes n- sary the stoppage of the cap machine until the strip ca e repaired.

After the coating is dry, the metal foil spots are assembled, coated side down, with the sealing disks. In case the metal foil is fed in a strip, spots may be cut out and deposited on the sealing disk, as above set forth.

At the time of assembly the coating material is softened by heat to render it adhesive and the assembled unit is subjected to pressure. In carrying out the invention according to what is now considered the best practice, the coating will be softened by heat after the spot is applied ~~cover is assembled~~. This may be accomplished in any suitable manner, as by a heated plunger or a plunger and heated table. The heat softens the coating and renders it adhesive and the pressure serves to unite the spot to the cork. In cutting disks from this improved laminated strip having an adhesive stratum bonded thereto, there is no tendency toward mutilation of the adhesive layer by reason of possible drag of the cutting dies, and each disc, as delivered from the die to within a cap, will present a continuous uninterrupted adhesive surface upon the disk so as to insure, by the subsequent application of heat and pressure, a bond between the disk and the cap cushion layer coextensive in area with the disk.

This possibility of securing a clean cut by the dies for forming the disks, both as to the non-absorptive and gas impervious, and as to the adhesive stratum, insures an effective bond entirely about the edge of the spot or disc, thereby presenting a continuous barrier of non-absorptive and gas impervious material at the space between the disk and the cap which will effectively prevent the seepage of gas or fluid in a bottle

between the disk and the portion of the cap to which it is applied.

Referring to the accompanying drawings, there is shown suitable mechanism for coating the strip and for cutting disks therefrom and adhesively uniting the disk to caps at the time of the assembly of the disks with the caps. In the drawings,

Figure 1 is a diagrammatical view showing the coating of the strip.

Figure 2 is a longitudinal sectional view of a fragment of the strip.

Figure 3 is a side elevational view partly in section showing one step in the assembly operation.

Figure 4 is a view similar to Figure 3 showing the spot as it is cut and adhesively united to the cap at the time of assembly.

Figure 5 is an interior face view of the completed cap, and

Figure 6 is a cross-sectional view of the cap shown in Figure 5 showing the use of additional pressure means which may be utilized following the action of the punch as illustrated in Figures 3 and 4.

The strip of facing material should have the characteristic of aluminum foil. That is to say, it should present one surface which is non-absorbent and gas impervious. This strip may be fed from a reel 10 to a reel 11, suitably separated so that the adhesive coating may be applied and hardened between the time any portion of the strip leaves the reel 10 and is wound upon the reel 11. For the purpose of applying the adhesive, the same may be maintained in a trough 12, positioned beneath an adhesive applying roll 13, between which and a roll 14, the strip passes, so that as the rolls are rotated the adhesive is applied to the undersurface thereof. As will be understood, the adhesive hardens between the time it is applied and the winding of the laminated strip upon the reel 11.

The completed spot material or liner is illustrated in Figure 2, and comprises the layer 15 of non-absorbent and gas impervious material, such as aluminum foil, having on one surface the coating 16 of adhesive, which is preferably of the thermoplastic character hereinbefore described. This adhesive is waterproof or liquid resistant, and will be normally hard, i. e., non-tacky, at room temperature, so that the material may be conveniently handled in strip form, but quickly softens under the application of heat, becoming tacky, so that upon the application of pressure, the laminated disk will be adhesively retained in the cap. The preferred method of applying the material to the cap is to utilise, at the time of assembly, both heat and pressure to unite the spot to the cork or cushion material insert or facing of the cap.

In Figures 3 and 4, there is shown a suitable mechanism for applying the disk and adhesively uniting it to the cork insert at the time the ~~strip~~ disk is punched from the ~~disk and assembled with the cap~~ strip.

The cap 17 is of the conventional crown type having an interior facing 18 of cushion material, such as composition cork retained in the cap as by an adhesive layer 17'; the cushion disk and adhesive may be applied to the cap in any suitable manner, for example, as described in the patent to Marsa, No. 1,603,786, granted October 19, 1926. The caps, with the cushion disks inserted therein, may be positioned beneath the cutting dies 19, 20, by means of a traveling bed 21 having suitable sockets for receiving the cap so as to position the same accurately beneath the cutting dies. The strip material for forming the spot is fed beneath the die 20 with the adhesive coating 16 facing the cap, and when the die descends it will cut from the strip, which is fed by any suitable means (not shown), a spot or facing 22 of the character illustrated in Figures 5 and 6. The spot or disk is preferably of smaller diameter than the cap facing so as to form a substantially centrally disposed spot which leaves around its edge an exposed portion of the cushion material adapted to engage the edge of a bottle neck, the spot being of sufficient size to close the bottle mouth and prevent contact of the contents with the cushion material.

As will be observed (Figures 3 and 4) as the punch 20 descends, it cuts from the strip a spot of the size shown in Figure 5, and continued downward movement presses this disk upon the cushion layer 18.

The punch 20 may be maintained at an elevated temperature, as by means of a burner 23, and the temperature should be sufficient to fuse or soften the adhesive coating and make it tacky so that, at the time the disk is assembled with the cap, the heat and pressure will cause the disk to be adhesively united to the surface of the cushion material with sufficient permanency to insure that the position will be retained and avoid likelihood of displacement of the disk thereafter.

The assembled unit is then cooled and the cooling may advantageously be coupled with pressure, for example, by a plunger. Cooling may be effected in any suitable manner, being carried out to the congealing point of the coating material.

It may be desirable to secure the spot in position, prior to the heat and pressure steps, sufficiently to prevent dislodgement of the spot during any interval between assembling and final sticking. This may be accomplished, for example, by preheating the assembled crown, to soften the coating, as soon as the metal foil spot is deposited. The coating becomes tacky enough to hold the metal foil spot from getting out of position during ordinary passage through assembling apparatus.

The resulting crown has a firmly secured metal foil spot which is not liable to become loose in use, owing to the fact that the adhesive substance is not soluble in liquids more commonly sealed by crown corks. Moreover, when the metal foil is assembled with the sealing disk, it is already prepared for being stuck in place, the sticking being accomplished by the simple application of heat and pressure. The coating operation is a simple one and the coated metal foil is easily handled because the dry coating is not tacky.

A cap made in accordance with this method possesses the advantage of a substantially uniform and complete distribution of the adhesive layer throughout each spot or facing disk. The method has the advantage of eliminating the labor of associating a separate adhesive strip and a strip of facing material, and the further advantage of enabling higher speeds to be maintained in the facing spot applying machine. The elimination of the danger of breakage of a separate adhesive tissue strip avoids the frequent stoppage of the machine, which was unavoidable due to the handling of the somewhat fragile and elastic adhesive tissue.

It is preferable after the disk 15 has been bonded to the cork disk 18, to thereafter subject them to continuing heat and pressure for a sufficient interval to ensure the complete fusion of the gutta percha and a close adhesion of every portion of the disk 15 to the disk 18. For this purpose, I have shown (Figure 6) a carrier i and a spring pressed plunger j. In the drawings, I have shown the punch 20 and plunger j as being heated by gas jets, but this is immaterial to the invention and other heating means may be employed.

1439

1683

I CLAIM:

1. The method of assembling linings for sealing pads in receptacle closure caps, consisting in providing caps with sealing pads therein and a web of lining material arranged with an adhesive surface non-viscous at normal temperature, heating the pads in the caps, and severing linings from the web of lining material and assembling the linings as they are severed from the web in the caps with the adhesive surface in contact with the heated pads to render the adhesive viscous and effect adhesion of the linings to the pads.

2. The method of assembling linings for sealing pads in receptacle closure caps, consisting in providing caps with sealing pads therein and a web of lining material arranged with an adhesive surface non-viscous at normal temperature, heating the pads in the caps, severing linings from the web of lining material and assembling the linings as they are severed from the web in the caps with the adhesive surface in contact with the heated pads to render the adhesive viscous and effect adhesion of the linings to the pads, and then placing the linings in the caps under heat and pressure to effect an intimate adhesion between the linings and pads.

8. The method of assembling linings for sealing pads in receptacle closure caps, consisting in providing caps with sealing pads therein and a web of lining material arranged with an adhesive surface non-viscous at normal temperature, heating the pads in the caps, severing the linings from the web of lining material and assembling the linings as they are severed from the web in the caps with the adhesive surface in contact with the heated pads to render the adhesive viscous and effect adhesion of the linings to the pads, then placing the linings in the caps under heat and pressure to effect an intimate adhesion between the linings and pads, and then placing the linings assembled in the caps under pressure during the cooling thereof.

9. In apparatus for assembling and securing linings to pads in closure caps, punch and die mechanism, a cap support adapted to position caps relative to the punch and die mechanism, means to position a web of lining material having an adhesive surface normally non-viscous to the punch and die mechanism to be severed into spot linings and positioned in the cap centrally of and with the adhesive surface abutting the pads by the punch and die mechanism, and a heated plunger to which the caps are delivered from the punch and die mechanism to place the linings under heat and pressure and effect an intimate adhesion between the linings and the pads.

METHOD OF MANUFACTURING
BOTTLE CAPS & APPARATUS THEREFOR,

Filed April 4, 1933. Div. 14.

* * *

U. S. PATENT OFFICE
APR 10 1933
DIVISION 14

April 4, 1933

Hon. Commissioner of Patents,
Washington, D. C.

Sir:

With reference to the accompanying application, attention is called to the fact that claims 1, 2 and 3 are respectively claims 28, 29 and 30 of the patent to Johnson, No. 1,852,578, granted April 5, 1932.

Claim 4 is substantially claim 19 of the Johnson patent, and it is thought that in view of the similarity, this claim should also be involved in interference with the Johnson patent. This application is a division of applicant's allowed case Serial No. 494,201, filed Nov. 7, 1930 (Div. 50) and the latter application is, in turn, a division of Serial No. 159,745, filed Jan. 7, 1927, now patent No. 1,788,260, granted Jan. 6, 1931.

It is to be noted that the issued patent does not disclose the prebeating of the crown or pad within the crown. Furthermore, it is to be noted that the said patent was cited by the Examiner against a broader claim (38) presented by Johnson and the said claim was canceled. However, claims 28, 29 and 30 were allowed over the disclosure of the Warth patent No. 1,788,260.

Therefore, the said claims have already been held by the Examiner to be patentable over the disclosure of the Farth patent or, in other words, divisible subject matter.

With respect to the step of "heating the pads in the caps", the Examiner's attention is called to the following statement in the specification of this application:

> "This may be accomplished, for example, by preheating the assembled crown, to soften the coating, as soon as the metal foil spot is deposited." (Page 12, line 8, et seq.,)

With respect to the step of "placing the linings in the caps under heat and pressure to effect an intimate adhesion between the linings and pads" (claim 2), attention is called to the following statement in the specification:

> "At the time of assembly the coating material is softened to render it adhesive and the assembled unit is subjected to pressure. In carrying out the invention according to what is now considered the best practice, the coating will be softened by heat after the crown is assembled." (Page 8, line 10 et seq.,)

With respect to the stage of "then placing the linings assembled in the caps under pressure during the cooling thereof", (claim 3) note the following statement in the specification of this application:

> "The assembled unit is then cooled and the cooling may advantageously be coupled with pressure, for example, by a plunger. Cooling may be effected in any suitable manner, being carried out to the congealing point of the coating material." (Page 12, line 1-4)

Regarding claim 4, the drawings clearly illustrate the apparatus described and are based upon the original disclosure. The punch and die mechanism is clearly illustrated in the drawings and is, in fact, conventional in the art. It is disclosed in applicant's copending application, Ser. No. 360,895, filed May 5, 1929. Referring to the "heated plunger" to which the caps are delivered from the punch and die mechanism to have heat and pressure applied, this is distinctly described on page 8,

line 14 et seq., as follows:

> "This may be accomplished in any suitable manner as by a heated plunger or a plunger and heated table. The heat softens the coating and renders it adhesive and the pressure serves to unite the spot to the cork".

Such a heated plunger is illustrated, for example, in Fig. 6, and is described on page 13.

The means for feeding the strip is generally known in the art and is described.

It is requested that an interference be declared promptly.

Respectfully,

Lockwood, Dewey, Alexander & Kane

Attorneys.

Please find below a communication from the EXAMINER in charge of this application.

Thomas E. Robertson
Commissioner of Patents.

April 14, 1933

Applicant: Albin H. Warth

Cushman, Darby & Cushman
American Security Bldg.
Washington, D. C.

Ser. No. 664,410
Filed Apr. 4, 1933
For Method of Manufacturing Bottle Caps and Apparatus Therefor.

This case has been examined and the following art is cited:

Alberti et al 1,401,300 Dec. 27, 1921 113-80

The statement on page 2, lines 6 to 9, inclusive, in regard to the present application being a division of application, Serial No. 494,201, filed November 7, 1930, which is in turn a division of application, Serial No. 159,743, now Patent No. 1,788,260, should be amended to read a continuation in part rather than "division", it being noted that Fig. 6 in this application and description thereof on page 13 was not in the original application. No showing is made in the said parent case of a heated plunger to which the caps are delivered from a punch and die mechanism as called for in claim 4 of this application.

Claim 4 is also rejected as failing to patentably distinguish from Alberte et al, above cited. This apparatus claim is not allowable over the reference merely on the kind of strip material applied to the cork. Obviously the punch 98 as seen in Figs. 1 and 10 will work just as well if adhesive is applied to the strip rather than in liquid condition to the cork pad. As seen in Figs. 1, 2 and 13, after

the liners have been positioned on the cork pad in the cap, heated plungers 112, 113 and 114 effect intimate adhesion of the liner and cork pad as called for in the claim.

An interference will immediately be declared between claims 1, 2, and 3 of this application and claims 28, 29, and 30, respectively, of Johnson Patent No. 1,852,578.

For Method of Manufacturing Bottle Caps and Apparatus Therefor.

APR 20 1933

The case, above referred to, is forwarded to the Examiner of Interferences because it is adjudged to interfere with others, hereafter specified. The question of priority will be determined in conformity with the Rules. The interference will be identified as No. 66201 On or before MAY 15 1933

the statement demanded by rule 110 must be sealed up and filed with the subject of invention, and name of party filing it, indorsed on the envelope. The subject-matter involved in the interference is

Count 1. The method of assembling linings for sealing pads in receptacle closure caps, consisting in providing caps with sealing pads therein and a web of lining material arranged with an adhesive surface non-viscous at normal temperature, heating the pads in the caps, and severing linings from the web of lining material and assembling the linings as they are severed from the web in the caps with the adhesive surface in contact with the heated pads to render the adhesive viscous and effect adhesion of the linings to the pads.

Count 2. The method of assembling linings for sealing pads in receptacle closure caps, consisting in providing caps with sealing pads therein and a web of lining material arranged with an adhesive surface non-viscous at normal temperature, heating the pads in the caps, severing linings from the web of lining material and assembling the linings as they are severed from the web in the caps with the adhesive surface in contact with the heated pads to render the adhesive viscous and effect adhesion of the linings to the pads, and then placing the linings in the caps under heat and pressure to effect an intimate adhesion between the linings and pads.

Count 3. The method of assembling linings for sealing pads in receptacle closure caps, consisting in providing caps with sealing pads therein and a web of lining material arranged with an adhesive surface non-viscous at normal temperature, heating the pads in the caps, severing the linings from the web of lining material and assembling the linings as they are severed from the web in the caps with the adhesive surface in contact with the heated pads to render the adhesive viscous and effect adhesion of the linings to the pads, then placing the linings in the caps under heat and pressure to effect an intimate adhesion between the linings and pads, and then placing the linings assembled in the caps under pressure during the cooling thereof.

Serial No. 664,410 - - 2

The interference involves your application above identified and a patent, No. 1,852,578, granted April 5, 1932, for Method and Apparatus for Assembling Linings in Receptacle Closure Caps, Serial No. 409,793, filed November 28, 1929, by John A. Johnson, whose post office address is 84-16-86th Street, Woodhaven, N. Y., and whose attorney is John O. Seifert, 277 Broadway, New York, N.Y.

The relation of the counts of the interference to the claims of the respective parties is as follows:

COUNTS	MARTH	JOHNSON

MAILED
MAY 15 1934

Interference No. 66,201 in which this application was involved having terminated favorably to this applicant, claims 1, 2, and 3, which constituted counts of the above identified interference, are allowed.

The step of heating the pads in the caps called for in claims 1, 2 and 3 should be suitably illustrated in the drawings.

Attention is directed to the action of April 14, 1933 in regard to the specification and in regard to the rejection of claim 4 for the reasons stated therein. The rejection of this claim is repeated for the reasons stated in the action.

Hon. Commissioner of Patents,

Washington, D. C.

Sir:

We hereby authorize and request entry of the following amendments in the above entitled application.

IN THE DRAWINGS

Please enter the accompanying sheet.

IN THE SPECIFICATION

Page 2

Line 11, after "disk" insert --or pad--.

Line 12, after "disks" insert --or pads--.

Line 17, change "spot center" to --center spot--.

Line 18, before the paragraph beginning "These spot center crowns etc." insert the following paragraph:

A commercially practicable method for manufacturing center spot crowns must ensure a high speed of production and accurate positioning of the center spot. An object of the present invention is to provide a method which will permit produc-

tion at the rate of from 400 to 600 per minute, i. e., application of the center spots to the sealing pads at such a rate. A further object is to ensure accurate positioning or centering of the facing or spot while maintaining this high speed.

Line 18, change "spot center" to --center spot--.

Page 6

Line 30, after "fluid" insert --or plastic--.

Same line (30) cancel "and cold".

Page 8

Line 10, after "softened" insert --by heat--.

Line 14, cancel "crown is assembled" and substitute --spot is applied--.

Line 15, cancel "as" and substitute --for example--.

Line 16, before the period insert --such as illustrated in Figure 6 of the accompanying drawing--.

Page 9

In the brief description of Figure 5 cancel "and".

Same page add the following:

Figure 7 illustrates a suitable means for applying heat to the sealing pads or disks for preheating the assembled crowns which are fed to the punch whereby to effect adhesion of the center spot as soon as it is deposited, and

Figure 8 is a view illustrating another mechanism suitable for preheating.

Page 10

Line 17, at the end of the line insert --thermoplastic--.

Next to the last line cancel "strip" and substitute --disk--.

Same line cancel "disk and assembled with the cap" and substitute --strip.--

Page 11

Line 7, after "disks" insert --or pads--.

Line 24, after the period insert --As hereinafter described, the method contemplates a preheating of the assembled crown, i.e., the metal shell with a sealing pad therein, before the spot is deposited so that the spot will adhere to the pad as soon as it is deposited.--

Line 25, after "may" insert --, if desired,--.

After the last line insert the following paragraph:

--As hereinbefore stated, after the spot is positioned on the sealing pad heat and pressure may be applied, as by a plunger or a plunger and heated table. In Figure 6 there is shown for this purpose a carrier 1 and a spring-pressed plunger 1. The plunger 1 is heated by gas jets, and thus the plunger serves as means for applying a continuing heat and pressure after the punching operation to ensure complete fusion of the adhesive and a close adhesion of every portion of the disk 15 to the disk 18.--

Page 12

Line 2, after "plunger" and before the period insert --such as illustrated in Figure 6, but which would not, of course, be heated--.

Lines 1 to 4, transpose this paragraph so that it follows the paragraph ending with present line 15.

Line 9, after "crown" insert --i. e., metal shell with the sealing pad or disk therein--.

Line 9, cancel the comma (second occurrence).

Line 10, cancel "in either case" and capitalize "the" (second occurrence).

Line 11, before "becomes" insert --thus--.

Same line (11) after "enough" insert --, as soon as deposited on the sealing pad,--.

-2-

Line 13, after the period insert the following:

In Figure 7, there is illustrated a suitable means for preheating the sealing pads to ensure adherence of the spot as soon as deposited. A burner 24 is positioned over the conveyor 21 and spaced sufficiently therefrom to apply to the pads heat sufficient to cause the spots to adhere to the latter as soon as deposited. This burner may be disposed within a hood 25 which confines the heat and tends to direct the same against the pads. As will be understood, it is sufficiently elongated to create sufficient heat for the purpose desired. This heater may be positioned immediately in advance of the punch 20 so that heat is not appreciably dissipated or lost before the punching operation. In Figure 8 there is illustrated another mechanism which may be used for preheating. A plunger 26 maintained at an elevated temperature, as by a gas burner 27, when positioned immediately in advance of the punch may be utilized to raise the temperature of the pads sufficiently to cause the spot to adhere to the pads as soon as deposited thereon.

IN THE CLAIMS

Cancel claim 4.

REMARKS

This application has been carefully reviewed in the light of the Official action of May 15th.

The Examiner's attention is called to the fact that the earlier applications referred to on page 2 of the specification contain a clear basis for the disclosure in Figure 6 and the description appearing on page 13. Hence, this application is a division of the earlier applications. If the Examiner will refer to page 8 of the present specification, he will find the following statement:

> "In carrying out the invention according to what is now considered the best practice, the coating will be softened by heat after the crown is assembled. This may be accomplished in any suitable manner, as by a heated plunger or a plunger and heated table."

This exact language appeared in the earlier cases referred to. In Serial No. 494,201, filed Nov. 7, 1930, note page 4, lines 24 to 28. In Serial No. 159,743, filed Jan. 7, 1927 (now patent 1,788,280) note page 8, lines 5 to 9. In each earlier application, the disclosure appears in exactly the same language. It is submitted that this disclosure is a clear basis for the illustration in Figure 6, and therefore we submit that the present application is properly designated as a division of the earlier cases.

The new drawing required is submitted herewith, and we think that the same fully meets the requirement for illustration of the preheating step.

The case is thought to be in condition for allowance, which is solicited.

Respectfully,

Attorneys.

Your APPLICATION for a patent for an IMPROVEMENT in

METHOD OF MANUFACTURING BOTTLE CAPS

filed Apr.4,1933 has been examined and ALLOWED with 3 claims.

The final fee, THIRTY DOLLARS, WITH $1 ADDITIONAL FOR EACH CLAIM ALLOWED IN EXCESS OF 20, must be paid not later than SIX MONTHS from the date of this present notice of allowance. If the final fee be not paid within that period, the patent will be withheld, but the application may be renewed within one year after the date of the original notice with a renewal fee of $30 and $1 additional for each claim in excess of 20.

The office delivers patents upon the day of their date, on which date their term begins to run. The preparation of the patent for final signing and sealing will require about four weeks, and such work will not be begun until after payment of the necessary final fee.

When the final fee is paid, there should also be sent, DISTINCTLY AND PLAINLY WRITTEN, the name of the INVENTOR, TITLE OF THE INVENTION, AND SERIAL NUMBER AS ABOVE GIVEN, DATE OF ALLOWANCE (which is the date of this circular), DATE OF FILING, and, if assigned, the NAMES OF THE ASSIGNEES.

If it is desired to have the patent issue to an ASSIGNEE OR ASSIGNEES, an assignment containing a REQUEST to that effect, together with the FEE for recording the same, must be filed in this office on or before the date of payment of the final fee.

After issue of the patent, uncertified copies of the drawings and specifications may be purchased at the price of TEN CENTS EACH. The money should accompany the order. Postage stamps will not be received.

The final fee will NOT be received from other than the applicant, his assignee or attorney, or a party in interest as shown by the records of the Patent Office.

NOTICE.—WHEN THE NUMBER OF CLAIMS ALLOWED IS IN EXCESS OF 20, NO SUM LESS THAN $30 PLUS $1 ADDITIONAL FOR EACH CLAIM IN EXCESS OF TWENTY CAN BE ACCEPTED AS THE FINAL FEE.

Respectfully,

Commissioner of Patents.

Cushman, Darby & Cushman

UNITED STATES PATENT OFFICE

1,967,195

METHOD OF MANUFACTURING BOTTLE CAPS

Albin H. Warth, Baltimore, Md., assignor to Crown Cork & Seal Company, Inc., Baltimore, Md., a corporation of New York

Original application November 7, 1930, Serial No. 494,201, which in turn is a division of Serial No. 159,743, January 7, 1927, now Patent No. 1,788,260, dated January 6, 1931. Divided and this application April 4, 1933, Serial No. 664,410

3 Claims. (Cl. 113—30)

This invention relates to a method of producing closures of the type in which a sealing disk has a facing. This type of closure is characterized by the provision, upon the interior cushion or sealing disc, of a facing or spot having a surface which protects the cushion material from the liquids and gases.

This application is a division of my copending application, Serial No. 494,201, filed November 7, 1930, and the latter is a division of my application, Serial No. 159,743, filed January 7, 1927, now Patent No. 1,788,260, granted January 6, 1931.

Closures of the well known crown cork type comprise a metal shell having a skirt and a resilient sealing disk or pad usually made of cork. For some uses, the sealing disks or pads are given a facing, e. g., tin foil, or aluminum foil, these materials or other materials of protective character being suitable to provide a non-absorbent, gas impervious, and acid resistant facing. Ordinarily this facing is of smaller diameter than the cork disks and such crowns are known in the trade as "center spot crowns".

A commercially practicable method for manufacturing center spot crowns must ensure a high speed of production and accurate positioning of the center spot. An object of the present invention is to provide a method which will permit production at the rate of from 400 to 600 per minute, i. e., application of the center spots to the sealing pads at such a rate. A further object is to ensure accurate positioning or centering of the facing or spot while maintaining this high speed.

These center spot crowns have been produced in various ways. According to one method a slot or groove is cut in the cork disk and the spot is given an inturned rim which is inserted in the slot. This method is objectionable because of its expense and because the tin foil spots are apt to drop out. According to another method the spots are pasted to the cork disks by a casein paste or a glue. In crowns so made the spots tend to loosen as the paste or glue is attacked by the packaged liquids. Furthermore, such method involves difficulties in handling and in applying the paste or glue. According to still another method, the spots are secured by an underlying and separately formed and deposited tissue of gutta percha or coated paper. In crowns so made, like objections are met with. For example, one difficulty in applying disks made from separate strips, such as gas and acid resistant material and the adhesive tissue strips, has arisen from the necessity for feeding the two strips to the punching and assembly machine. There is not only difficulty in feeding the strips, but in cutting the separate tissue strip with a clean, sharp edge so as to insure the binding stratum of adhesive being coextensive in area with the disc of liquid resistant material. As will be understood, the adhesive stratum is intended to act not only as a cement, but also as a water-proof, non-absorbent, gas impervious medium for avoiding the possibility of the contents of a bottle getting between the facing disk and the material of the cap, either the metal shelf itself or a cushion disk of cork or composition cork.

Furthermore, when using superimposed strips of the facing material and of adhesive tissue, it was essential, to bond the adhesive tissue to both the material of the cushion disc in the cap and the facing material.

In preparing the rolls of facing material and adhesive tissue, the practice usually followed was to form a roll of the tissue in strips of the desired width, and to unwind this roll and a roll of the facing material while feeding the two strips one over the other into the disk forming and assembling machine. This is a troublesome and expensive operation, because of the frequent breakage of the adhesive tissue and the necessity for using fairly heavy tissue to minimize this tendency. This is due partly to the fact that the facing material was substantially non-elastic, while the adhesive tissue possessed a certain degree of elasticity, thus introducing a factor of difficulty in securing a uniform paying of both the facing strip and the gutta percha tissue strip.

It is desirable, in the use of facing disks of the character above referred to, that the adhesive stratum be as thin as possible, and yet be continuous throughout the entire area of the facing disk, and particularly that it be uninterrupted about the edge of this disk, since at this point the disk should be firmly bonded so as to effectively seal the joint above the edge of the facing disk. When cutting and applying the disk of material and adhesive, there is no means of ascertaining whether the desired conditions are present in the completed cap. Consequently, there is always likelihood of imperfectly faced caps being produced.

With the above conditions in mind, I have provided material, in strip form, for facing bottle caps, in which one surface of the strip is provided with a firmly adherent, continuous thin facing of adhesive, thus avoiding all necessity for

assembling strips of facing material and of adhesive tissue preparatory to their use in the bottle cap facing machine, and all of the disadvantages growing out of this practice.

In the strip material of my invention, a very thin stratum of adhesive is evenly distributed upon one face of a strip of facing material. The adhesive is not only firmly bonded to this material, but has a smooth surface finish of sufficient thickness to form the desired firm bond between a disk cut from the strip and the material of the cap to which such disk is cemented.

Furthermore, adhesive tissue must be of a thickness to have sufficient inherent strength to permit of its being stripped from a roll in a mill for working same, and to admit of its being cut to the desired width and to be handled in the winding and the disk applying machines, and during the process of its production it has more or less of a longitudinally extending grain, as distinguished from its normal granular formation.

In the application of heat, when bonding the facing material to the cap, when utilizing adhesive tissue, a tendency of the adhesive is to break up into slightly isolated, small globules, thus interrupting the continuity of the bonding stratum. Whether this is due to irregularities in the surface of the facing strip, or to a shrinkage of the adhesive tissue when fused, I have been unable to determine. In the strip of my invention, however, the adhesive is thoroughly distributed throughout one face of the facing material, and the above conditions do not develop in the subsequent handling of the strips.

It is an object of the present invention to provide a method of producing spot center crowns such that the spots may be rapidly and economically secured to the sealing disks and such that they are firmly secured and not liable to become loosened in use.

Another object of the invention is to provide a method in which the sealing discs or "spots" when punched from the strip and delivered to the cushion pad will be stuck in position instantly or as soon as deposited whereby during subsequent operations they will not move from the accurately centered position in which they are placed by the punch and die mechanism. This is preferably accomplished by preheating the sealing pad or cushion sufficiently to cause the thermoplastic coating on the disc to fuse sufficiently when it engages the pad to adhere instantly to the sealing pad.

With these general objects in view, the invention consists in the method which will be first described and then more particularly pointed out in the claims.

According to the method of the present invention, the strip material, such as metal foil, is coated with a substance that is devoid of tackiness when dry and has adhesive qualities when soft. In carrying out the method according to what is considered the best practice, the adhesive substance is such that it can be applied cold, i. e., at room temperatures, and is insoluble in cold water. While various materials may be used, I have found a suitable adhesive in a solution of dammar resin and rosin in mineral spirit or turpentine, to which is added 5% or less of a vegetable oil, such as soya bean or China-wood oil. The dammar gum and rosin may be in the proportion of 35% to the whole. The adhesive may have a drier of lead resinate or the like in a proportion of 2% or less. Another example of a suitable gum type of adhesive is gutta percha or a gutta percha containing compound which have characteristics similar to the composition previously described. Among such characteristics are substantially non-tackiness or adherence at room temperature a high degree of flexibility, insolubility in and imperviousness to moisture or water, acid resistance and heat fusibility, i. e., adapted to be brought to a tacky state by the mere application of heat and without the use of moisture. Such an adhesive is specified in my copending application, Serial No. 414,614, filed December 17, 1929, now Patent No. 1,899,782, granted February 28, 1933.

An adhesive of this character provides a highly flexible adhesive layer continuously united with the facing material. Moreover, such an adhesive is highly resistant to the acids and alkalies ordinarily present in liquids which are to be capped. This is highly important in the manufacture of spot caps, since the liquids attack the adhesive around the edge of the spot. An adhesive of this character, which is not only waterproof, but resistant to acids and alkalies as well, maintains a firm adherent union of the facing or spot material with the cork disk. Due to its flexible character, it will not crack, and, therefore, it constitutes a flexible backing for the spot material.

While the coating may be applied to the material in various ways, it is conveniently applied in fluid or plastic form to a strip of foil from which the spots are to be cut. So far as the method of producing the strip is concerned, it is such that the effective distribution of the adhesive throughout the entire area of the facing material is assured, and this condition cannot be disturbed as a result of the cutting of disks from this material when in strip form. Furthermore, the adhesive surface may be thoroughly inspected while producing the strip material, so that any imperfect product may be discarded before it reaches the disk applying machine. In this connection it is noted that the spots may be conveniently assembled by feeding a strip of material over successive crown corks and cutting out a disk which is deposited on a cork, such assembling machinery being known in the art.

After the coating is applied to the material, it is dried. While this may be effected by air drying at room temperatures, it is more rapidly accomplished at a temperature of about 300° F. maintained for about three minutes. When dried the coating is devoid of tackiness so that the metal foil may be handled without difficulty or trouble. This is particularly advantageous when the metal foil is to be fed in strips because the application of the adhesive is carried out independently of the assembling steps. Moreover, the coating gives the thin metal foil more or less body, which facilitates feeding and cutting.

Since the adhesive is applied directly to the surface of the facing or spot material and firmly bonded thereto, there is no likelihood of difficulties arising as a result of separation of the adhesive from the facing strip during the spot forming operation, either as a result of poor adherence or from suction or otherwise, such as frequently occurs when using superimposed strips of facing material and of adhesive tissue. Moreover, in handling this material the adhesive stratum is incapable of stretch or distortion relative to the spot strip as frequently occurs in the handling of separate strip of adhesive tissue and facing material where any stretch or distortion of the ad-

BLANK

PAGE

BLANK

PAGE

hesive stratum results in a defective cap and when the stretch is extreme, tearing of the adhesive tissue makes necessary the stoppage of the cap machine until the strip can be repaired.

After the coating is dry, the metal foil spots are assembled, coated side down, with the sealing disks. In case the metal foil is fed in a strip, spots may be cut out and deposited on the sealing disk, as above set forth.

At the time of assembly the coating material is softened by heat to render it adhesive and the assembled unit is subjected to pressure. In carrying out the invention according to what is now considered the best practice, the coating will be softened by heat after the spot is applied. This may be accomplished in any suitable manner, for example by a heated plunger or a plunger and heated table such as illustrated in Figure 6 of the accompanying drawings. The heat softens the coating and renders it adhesive and the pressure serves to unite the spot to the cork. I also prefer to preheat the cushion disc or pad in the metal cell so that, as soon as the spot is applied, the thermoplastic adhesive thereon will be fused or softened and thereby cause the spot to be fixed in the accurately centered position in which it is deposited and held against dislodgment during the subsequent steps and passage through the apparatus. In cutting disks from this improved laminated strip having an adhesive stratum bonded thereto, there is no tendency toward mutilation of the adhesive layer by reason of possible drag of the cutting dies, and each disc, as delivered from the die to within a cap, will present a continuous uninterrupted adhesive surface upon the disk so as to insure, by the subsequent application of heat and pressure, a bond between the disk and the cap cushion layer coextensive in area with the disk.

This possibility of securing a clean cut by the dies for forming the disks, both as to the non-absorptive and gas impervious, and as to the adhesive stratum, insures an effective bond entirely about the edge of the spot or disc, thereby preventing a continuous barrier of non-absorptive and gas impervious material at the space between the disk and the cap which will effectively prevent the seepage of gas or fluid in a bottle between the disk and the portion of the cap to which it is applied.

Referring to the accompanying drawings, there is shown suitable mechanism for coating the strip and for cutting disks therefrom and adhesively uniting the disk to caps at the time of the assembly of the disks with the caps. In the drawings,

Figure 1 is a diagrammatical view showing the coating of the strip.

Figure 2 is a longitudinal sectional view of a fragment of the strip.

Figure 3 is a side elevational view partly in section showing one step in the assembly operation.

Figure 4 is a view similar to Figure 3 showing the spot as it is cut and adhesively united to the cap at the time of assembly.

Figure 5 is an interior face view of the completed cap.

Figure 6 is a cross-sectional view of the cap shown in Figure 5 showing the use of additional pressure means which may be utilized following the action of the punch as illustrated in Figures 3 and 4.

Figure 7 illustrates a suitable means for applying heat to the sealing pads or disks for preheating the assembled crowns which are fed to the punch whereby to effect adhesion of the center spot as soon as it is deposited, and

Figure 8 is a view illustrating another mechanism suitable for preheating.

The strip of facing material should have the characteristic of aluminum foil. That is to say, it should present one surface which is non-absorbent and gas impervious. This strip may be fed from a reel 10 to a reel 11, suitably separated so that the adhesive coating may be applied and hardened between the time any portion of the strip leaves the reel 10 and is wound upon the reel 11. For the purpose of applying the adhesive, the same may be maintained in a trough 12, positioned beneath an adhesive applying roll 13, between which and a roll 14, the strip passes, so that as the rolls are rotated the adhesive is applied to the undersurface thereof. As will be understood, the adhesive hardens between the time it is applied and the winding of the laminated strip upon the reel 11.

The completed spot material or liner is illustrated in Figure 2, and comprises the layer 15 of non-absorbent and gas impervious material such as aluminum foil, having on one surface the coating 16 of adhesive, which is preferably of the thermoplastic character hereinbefore described. This adhesive is waterproof or liquid resistant, and will be normally hard, i. e., non-tacky, at room temperature, so that the material may be conveniently handled in strip form, but quickly softens under the application of heat, becoming tacky, so that upon the application of pressure, the laminated disk will be adhesively retained in the cap. The preferred method of applying the material to the cap is to utilize, at the time of assembly, both heat and pressure to unite the spot to the cork or cushion material insert or facing of the cap.

In Figures 3 and 4, there is shown a suitable mechanism for applying the disk and adhesively uniting it to the cork insert at the time the disk is punched from the strip.

The cap 17 is of the conventional crown type having an interior facing 18 of cushion material, such as composition cork retained in the cap as by an adhesive layer 17'; the cushion disk and adhesive may be applied to the cap in any suitable manner, for example, as described in the patent to Marsa, No. 1,603,786, granted October 19, 1926. The caps, with the cushion disks or pads inserted therein, may be positioned beneath the cutting dies 19, 20, by means of a traveling bed 21 having suitable sockets for receiving the cap so as to position the same accurately beneath the cutting dies. The strip material for forming the spot is fed beneath the die 20 with the adhesive coating 16 facing the cap, and when the die descends it will cut from the strip, which is fed by any suitable means (not shown), a spot or facing 22 of the character illustrated in Figures 5 and 6. The spot or disk is preferably of smaller diameter than the cap facing so as to form a substantially centrally disposed spot which leaves around its edge an exposed portion of the cushion material adapted to engage the edge of a bottle neck, the spot being of sufficient size to close the bottle mouth and prevent contact of the contents with the cushion material.

As will be observed (Figures 3 and 4) as the punch 20 descends, it cuts from the strip a spot of the size shown in Figure 5, and continued downward movement presses this disk upon the cushion layer 18. As hereinafter described, the method contemplates a preheating of the assem-

Page Tightly Bound

1469

bled crown, i. e., the metal shell with a sealing pad therein, before the spot is deposited so that the spot will adhere to the pad as soon as it is deposited.

The punch 20 may, if desired, be maintained at an elevated temperature, as by means of a burner 23, and the temperature should be sufficient to fuse or soften the adhesive coating and make it tacky so that, at the time the disk is assembled with the cap, the heat and pressure will cause the disk to be adhesively united to the surface of the cushion material with sufficient permanency to insure that the position will be retained and avoid likelihood of displacement of the disk thereafter.

As hereinbefore stated, after the spot is positioned on the sealing pad heat and pressure may be applied, as by a plunger or a plunger and heated table. In Figure 6 there is shown for this purpose a carrier *i* and a spring-pressed plunger *j*. The plunger *j* is heated by gas jets, and thus the plunger serves as means for applying a continuing heat and pressure after the punching operation to ensure complete fusion of the adhesive and a close adhesion of every portion of the disk 15 to the disk 18.

It may be desirable to secure the spot in position, prior to the heat and pressure steps, sufficiently to prevent dislodgment of the spot during any interval between assembling and final sticking. This may be accomplished, for example, by preheating the assembled crown i. e., metal shell with the sealing pad or disk therein, to soften the coating as soon as the metal foil spot is deposited. The coating thus becomes tacky enough, as soon as deposited on the sealing pad, to hold the metal foil spot from getting out of position during ordinary passage through assembling apparatus. In Figure 7, there is illustrated a suitable means for preheating the sealing pads to ensure adherence of the spot as soon as deposited. A burner 24 is positioned over the conveyor 21 and spaced sufficiently therefrom to apply to the pads heat sufficient to cause the spots to adhere to the latter as soon as deposited. This burner may be disposed within a hood 25 which confines the heat and tends to direct the same against the pads. As will be understood, it is sufficiently elongated to create sufficient heat for the purpose desired. This heater may be positioned immediately in advance of the punch 20 so that heat is not appreciably dissipated or lost before the punching operation. In Figure 8 there is illustrated another mechanism which may be used for preheating. A plunger 26 maintained at an elevated temperature, as by a gas burner 27, when positioned immediately in advance of the punch may be utilized to raise the temperature of the pads sufficiently to cause the spot to adhere to the pads as soon as deposited thereon.

The assembled unit is then cooled and the cooling may advantageously be coupled with pressure, for example, by a plunger such as illustrated in Figure 6, but which would not, of course, be heated. Cooling may be effected in any suitable manner, being carried out to the congealing point of the coating material.

The resulting crown has a firmly secured metal foil spot which is not liable to become loose in use, owing to the fact that the adhesive substance is not soluble in liquids more commonly sealed by crown corks. Moreover, when the metal foil is assembled with the sealing disk, it is already prepared for being stuck in place, the sticking being accomplished by the simple application of heat and pressure. The coating operation is a simple one and the coated metal foil is easily handled because the dry coating is not tacky.

A cap made in accordance with this method possesses the advantage of a substantially uniform and complete distribution of the adhesive layer throughout each spot or facing disk. The method has the advantage of eliminating the labor of associating a separate adhesive strip and a strip of facing material, and the further advantage of enabling higher speeds to be maintained in the facing spot applying machine. The elimination of the danger of breakage of a separate adhesive tissue strip avoids the frequent stoppage of the machine, which was unavoidable due to the handling of the somewhat fragile and elastic adhesive tissue.

I claim:

1. The method of assembling linings for sealing pads in receptacle closure caps, consisting in providing caps with sealing pads therein and a web of lining material arranged with an adhesive surface non-viscous at normal temperature, heating the pads in the caps, and severing linings from the web of lining material and assembling the linings as they are severed from the web in the caps with the adhesive surface in contact with the heated pads to render the adhesive viscous and effect adhesion of the linings to the pads.

2. The method of assembling linings for sealing pads in receptacle closure caps, consisting in providing caps with sealing pads therein and a web of lining material arranged with an adhesive surface non-viscous at normal temperature, heating the pads in the caps, severing linings from the web of lining material and assembling the linings as they are severed from the web in the caps with the adhesive surface in contact with the heated pads to render the adhesive viscous and effect adhesion of the linings to the pads, and then placing the linings in the caps under heat and pressure to effect an intimate adhesion between the linings and pads.

3. The method of assembling linings for sealing pads in receptacle closure caps, consisting in providing caps with sealing pads therein and a web of lining material arranged with an adhesive surface non-viscous at normal temperature, heating the pads in the caps, severing the linings from the web of lining material and assembling the linings as they are severed from the web in the caps with the adhesive surface in contact with the heated pads to render the adhesive viscous and effect adhesion of the linings to the pads, then placing the linings in the caps under heat and pressure to effect an intimate adhesion between the linings and pads, and then placing the linings assembled in the caps under pressure during the cooling thereof.

UNITED STATES PATENT OFFICE.

ALEXANDER BOGDÁNFFY, OF NEW YORK, N. Y., ASSIGNOR TO THE INTERNATIONAL CORK COMPANY, OF BROOKLYN, NEW YORK, A CORPORATION OF NEW YORK.

MACHINE FOR THE MANUFACTURE OF BOTTLE-CLOSURES.

1,169,608. Specification of Letters Patent. Patented Jan. 25, 1916.

Application filed July 5, 1913. Serial No. 777,466.

To all whom it may concern:

Be it known that I, ALEXANDER BOGDÁNFFY, a subject of the King of Hungary, and resident of the city of New York, in the county of Kings and State of New York, have invented certain new and useful Improvements in Machines for the Manufacture of Bottle-Closures, of which the following is a specification.

The present invention relates to a machine for the manufacture of bottle closures of the class known as "crown cork sealing caps or closures." Closures of this type comprise usually three parts, that is a metallic cap having a corrugated flange to be locked to the exterior of the bottle neck, a sealing disk or packing of cork or the like, and an impervious binding medium, for instance in the form of a disk, interposed between the metallic cap and the sealing disk. In manufacturing these caps, the binding material is fused or softened and the assembled closure subjected to pressure before the binding material sets or hardens, whereby the said binding material unites the sealing disk with the metallic cap. Usually the three parts mentioned are first assembled and the closure, as a whole, is then subjected to heating action to fuse the binding medium, and afterward pressure is applied. In other cases the caps contain only the binding material when heat is applied to the same, the sealing disk of cork or the like being inserted subsequently.

Heretofore the outer face of the cap has been subjected to heating action, the heat being conducted by the cap to the binding medium. It has been found in practice that only that portion or surface of the binding material which is in contact with the inner surface of the cap is fully fused, that portion or surface which contacts or is to contact with the sealing disk being softened only to a certain extent. The result of this is that, while the binding material is capable of being properly united with the cap, the union between the sealing disk and the binding material is often defective. When plain or undecorated caps are used, it might be possible to expose the same to heating conditions which might fuse the binding material thoroughly, but when decorated caps are charged with the binding material, and such caps subjected to heating action, the extent of exposure to properly fuse the binding material is ruinous to the said decorated caps, inasmuch as it affects the paint used in decorating the same and otherwise defaces the caps. Even plain caps cannot be heated to such an extent which is required to properly fuse both faces of the binding medium for the reason that the said caps are transported from one place to the other on the assembling and uniting machine at a speed which prevents the proper extent of exposure to heat.

One of the objects of the present invention is to provide a machine for the manufacture of closures, which produces a firm union between the three parts of the closure by reason of the binding medium being properly fused at its contact faces with the cap and packing disk, respectively, thereby obviating the defects above mentioned.

Another object of the invention is to devise a bottle closure assembling machine which prevents the feeding of the binding material and sealing disk to the respective assembling elements of the machine in case the cap advancing means fails to bring a metallic cap in proper relation to said assembling elements.

A further object of the invention is to provide a simple and effective means for carrying the caps in succession to the assembling elements of the machine, and the assembled closure to the uniting means of the same.

With these and other objects in view, which will more fully appear as the nature of the invention is better understood, the same consists in the combination, arrangement and construction of parts hereinafter fully described, pointed out in the appended claims and illustrated in the accompanying drawings, it being understood that many changes may be made in the size and proportion of the several parts and details of construction within the scope of the appended claims without departing from the spirit or sacrificing any of the advantages of the invention.

One of the many possible embodiments of the invention is illustrated in the accompanying drawings, in which:—

Figure 1 is a plan view of a machine constructed in accordance with the present invention; Fig. 2 is a side elevation thereof;

Page Tightly Bound

Fig. 3 is a sectional view of the cap feeding device; Fig. 4 is a section taken on line 4—4 of Fig. 3; Fig. 5 is a section taken on line 5—5 of Fig. 3; Fig. 6 is a plan view of the device shown in Fig. 3, certain parts being removed to more clearly show the interior construction; Fig. 7 is a section taken on line 7—7 of Fig. 6, additional parts being placed on top of it; Fig. 8 is a plan view of a detail of the device shown in Fig. 7; Fig. 9 is a plan view of a detail of the device shown in Fig. 6; Fig. 10 is a front elevation of the assembling means of the machine; Fig. 11 is a rear elevation of the device shown in Fig. 10; Fig. 12 is a side elevation thereof; Fig. 13 is a front elevation of the means for actuating the binding material feeding means; Fig. 14 is a side elevation thereof; Fig. 15 is a longitudinal vertical section taken through the means operating the device shown in Fig. 13; Fig. 16 is a section taken on line 16—16 of Fig. 15; Fig. 17 is a side elevation of a detail of the structure shown in Fig. 15; Fig. 18 is a side elevation also of a detail shown in Fig. 15; Fig. 19 is a plan view of the sealing disk feeding means; Fig. 20 is a rear elevation of a detail shown in Fig. 19; Fig. 21 is a side elevation of the mechanism shown in Fig. 20; Fig. 22 is a sectional elevation taken through the means for actuating the sealing disk feeding means; Fig. 23 is a sectional front elevation of the device shown in Fig. 22; Fig. 24 is a rear elevation of a detail of the device shown in Fig. 23; Fig. 25 is a sectional elevation taken through a portion of the uniting means of the machine; Fig. 26 is a plan view of the means for removing the finished product from the machine; and Fig. 27 is a central vertical section taken through the binding material cutting means.

Broadly speaking, the bottle closures are manufactured on the machine, forming the subject matter of the present application, as follows: The inner surface of a cap is first subjected to an intense heat, the result of which is twofold, that is, first, it evaporates or burns the greasy or oily substance usually covering or spotting the inner surface of the cap, thereby cleaning the said surface effectively, and, second, it heats the inner surface of the cap, whereby, when the impervious binding medium is deposited into the same, its contact surface with the cap is properly fused so that it is adapted to adhere perfectly to the inner surface of the cap. After the binding medium has been deposited into the cap, the exposed surface thereof is heated, resulting in a proper fusing of said surface. The binding medium being properly fused, a sealing disk or packing is placed into the cap, after which the assembled closure is subjected to pressure which firmly unites the parts thereof, the binding material being partly or wh hardened when the closure is discha from the machine.

Referring now more particularly to drawings, the numeral 30 indicates the porting frame of the machine, for inst casing-shaped, and provided with a h zontal top or table-section 31. A sub tial distance below the table-section is j naled in the frame the main driving s 32, to which rotation is imparted, for stance, by a belt running over a driving ley 33, which is in any suitable ma rigidly fastened to the said shaft. Near of the longitudinal edges of the table mounted upon the same a box-like struct 34, upon the top of which is disposed a p member 35, having a longitudinal groov in its underface, which is adapted to acc modate metallic caps that are fed therei in their inverted positions. This groove tends throughout the length of said p member. Parallel to said groove, and p particularly on each side thereof, is for in the under face of said plate membe longitudinal recess 37, said recesses open into said groove, and having slidably ranged therein each a feeding strip These strips are adapted to reciprocate the longitudinal direction of the box-l structure 34, and also transversely ther toward and away from each other. T feeding strips 38 are provided in their posite edges, denoted by the numerals 39, with registering substantially semi-circu notches 40, 40. The edges of these note are adapted, when the feeding strips moved toward and close to each other, grip firmly the head portions of the meta caps which are located in alinement w said notches in the groove 36, and, as said strips are advanced in the direction the longitudinal axis of the box-like str ture, to carry them forward a predetermin distance. The caps are brought in their verted positions into the groove 36 on chute 41, which receives them from a h per or similar structure, the construction which need not be described here as it d not form part of the present inventi The means for imparting to the feedi strips a to and fro motion in the direct of the longitudinal axis of the box-l structure 34, which motion will be here after termed "reciprocating motion", i cludes a disk 42, which is keyed or oth wise attached to the driving shaft, and p vided in one of its faces with a cam groo 43. In this groove is seated a roller 44, c ried by a lever 45, one end of which is f crumed at 46 to the frame, its other e carrying a pin 47, that is seated in a slot in the downwardly extending lug 49 of substantially H-shaped block 50. Th block is provided in each of its four le

h a cylindrical bore 51, through which drawn two parallel horizontal rocking fts 51′, which are mounted in the box-structure 34 parallel to the longitudinal of the latter. The block 50 is shiftably ged upon the said rocking shafts, and ded in its upper face with transverse es 52, into which project lugs 53 upon nderfaces of the feeding strips 38. The es 52 are of a length to permit the feeding strips to move toward and away from each other; this movement will be termed hereinafter "the swinging movement of the feeding strips". The swinging movement of the feeding strips is effected by a bar 54, which is pivoted to a bracket 54′, that is conducted in its up and down movement by vertical guides 55 upon the frame 30, the reciprocating movement of said bracket being caused by a roller 56, which is seated in the cam groove 43 and carried by said bracket. The upper end of the bar 54 is provided with a pin 57, seated in slots 58 of two bell-cranks 59, which are keyed, or otherwise attached, to the rocking shafts 51′, the free ends of their other arms engaging apertures 60 in slides 61, in the upper faces of which are formed longitudinal grooves 62, into which project downwardly extending lugs 63 upon the under faces of the feeding strips 38. The slides 61 are located in recesses 61′ in the upper face of the box-like structure, and are adapted to move toward and away from each other transversely of the said box-like structure.

From the foregoing it appears that the lever 45 causes a reciprocating motion of the feeding strips, and the bar 54 a swinging motion, that is to say a motion toward and away from each other. The cam groove 43 is shaped in such a manner and the rollers 44 and 56 disposed in such relation that, whenever the lever 45 swings toward the chute 41, the feeding strips are held in their open positions, that is to say away from each other, and, when the lever 45 has reached its outermost position in the direction stated, the feeding strips are caused by the bar 54 to move toward each other into gripping positions, the said feeding strips being kept in such gripping positions while the lever 45 moves in the opposite direction and until it has reached its outermost point in that direction, when the bar 54 causes said strips to recede from each other. When the lever 45 reaches its outermost position in the direction of the chute 41, its outermost notches are brought in operative relation to a cap just received from the chute. The feeding strips then move toward each other, grip the said cap and obviously those in front of the same, advance them a predetermined distance in the groove, and when reaching this position, the feeding fingers recede from each other, thereby leaving the caps at rest. In this manner there are always a plurality of caps in the groove 36, arranged at distances from each other which correspond to the distances between the notches in a feeding strip. All caps in the groove are brought to rest simultaneously and are also advanced simultaneously.

A cap received from the chute comes first to rest in registering position with a circular opening 64 in the plate member 35. Above this opening is arranged a heating means, consisting, preferably, of a gas burner 65 of the "Bunsen" type to cause a complete combustion of the illuminating gas in order to prevent unconsumed particles of carbon settling on the inner surface of a cap. Inasmuch as the caps travel in the groove 36 in their inverted positions, the mouth of the burner must point downward, the flame being directed to the inner surface of a cap by compressed air that is conducted to the said burner. The result of this action will be two-fold, first, it evaporates or burns the greasy or oily substance usually covering or spotting the inner surface of the cap, thereby cleaning the said surface effectively and, second, it heats the inner surface of the cap, whereby, when the impervious binding medium is deposited into the same, its contact surface with the cap will be properly fused so that it will be adapted to adhere perfectly to the inner surface of the cap. The removing of the oily or greasy substance materially aids such union.

After the inner surface of the cap has been heated in the manner described, it is brought by the feeding strips into registering position with a circular opening 66 in the plate member 35, stopping there to receive the binding medium. The binding medium is deposited into the cap in the form of a disk, which is cut from a strip 67 of suitably prepared paper or other material, that is wound upon a reel 68. This reel is journaled in the reel of the machine, the strip being conducted therefrom into a guide 69, to pass between the feeding rollers 70. The upper one of the feeding rollers is fixedly attached to a shaft 71, which is journaled in the frame of the machine and carries on its outer end a friction clutch 72. The clutch comprises a disk 73, keyed or otherwise attached to said shaft, and provided with a flange 74, in engagement with spring pressed dogs 75, which are carried by a lever, 76, the latter being loosely mounted upon the shaft 71, and provided with a pin 77 for actuating the same. When the lever 76 is swung in the direction of the arrow shown in Fig. 14 of the drawings, the disk 73 is given a turn through a corresponding distance, carrying with it the upper feeding roller 70, whereby the paper strip 67 is advanced a corresponding distance. When the lever 76 swings in

Page Tightly Bound

the other direction, obviously, the roller 70 remains stationary. The pin 77 is oscillated by means hereinafter to be described.

The rollers 70 advance the paper strip intermittently to the cutting means, comprising a tubular cutter 79, reciprocably arranged, in registering position with the opening 66, in a frame 80, that is disposed above the plate member 35. To the cutter 79 is secured a horizontally extending arm 81, carrying an actuating arm 82, to one end of which is pivoted at 83 the rod 84 of an eccentric 85, that is keyed, or otherwise attached, to the main driving shaft 32. To guide the movement of the actuating arm 82, its other end is pivoted at 86 to one end of a rod 87, the other end of which, in turn, is secured at 88 in a similar manner to a link 89, that is fulcrumed at 90 to the frame of the machine. Upon the downward movement of the cutter 79, a disk of binding material is cut from the strip 67, said disk being automatically forced, upon the upward movement of the cutter, by a stem 91 into the metallic cap. The stem 91 is slidably arranged in guides 92 within the cutter, and carries upon its upper end a weight 93. When, therefore, the cutter 79 moves upward, the weight 93 will force the stem 91 downward and thereby the paper disk into the cap. After this, upon the further upward movement of the cutter, the uppermost one of the guides 92 will engage the weight 93 and lift thus the stem 91 out of the opening 66 in the plate member 35. Around the opening 66 is formed a water jacket 66', in which circulates a cooling fluid to prevent the strip 67 from being affected by the heat of the burner 65.

The means for actuating the lever 76 of the friction clutch comprises a slide 94, which is reciprocably arranged in a vertical guide 95, formed upon the frame 80. This slide is provided with a horizontal slot 96, in which is seated the pin 77 of the lever 76, and in the guide 95 is formed an arc-shaped slot 97, through which the pin 77 projects. Within the slide 94 is disposed a catch 98, pivoted at 99 to the said slide and provided upon its upper end with a hook 100. A spring 101 tends to force the said catch toward and into engagement with one of the sides of the guide 95. A second slide 102 is also reciprocably arranged in the guide 95, and attached to the arm 81. To this slide is pivoted at 103 a downwardly extending pawl 104, its hook 105 being adapted to engage the hook 100 of the catch 98. A spring 106 forces the hook 105 of the pawl 104 toward and into engagement with the hook 100 of the catch 98. To the guide 95 is pivoted at 107 a lever 108, its lower end carrying a sleeve 109 which is seated in the opening 64 in the plate member 35, while its upper end is provided with a pin 110, which is adapted to project through an aperture 111 in the wall of the guide 95 into the latter. The front edge 109' of the sleeve 109 is tapered. Normally the hook 100 of the catch 98 is in engagement with the hook 105 of the pawl 104 as will be presently described; when, therefore, the arm 81 moves upward, the slide 94 moves therewith and thereby causes the lever 76 of the friction clutch to swing in the direction of the arrow shown in Fig. 14 of the drawings, advancing thus the paper strip a predetermined distance. Upon the downward movement of the arm 81, the paper disk is cut and deposited in the manner above described into the cap, the slide 94 being lowered by the slide 102, contacting therewith, thereby swinging the lever 76 in the opposite direction, during which movement obviously the shaft 71 of the feeding roller 70 remains stationary. If during the downward movement of the slides 94 and 102 there is no cap in registering position with the circular opening 64, the sleeve 109 drops to the bottom of the groove 36, the pin 110 being thus withdrawn from the guide 95. The spring 101 will then disengage the hook 100 of the catch 98 from the hook 105 of the pawl 104. When, therefore, the slide 102 moves upward, it will not carry with it the slide 94, and for this reason the paper strip 67 will not be advanced. In such case, obviously, upon the next downward movement of the cutter 79, no binding disk will be cut. In other words, whenever the feeding strips fail to bring a cap in registering position with the opening 66, no paper disk is cut, nor is one forced through the opening 66 into the groove 36. If a cap is brought into proper position relative to the opening 64, the said cap engages the front edge 109' of the sleeve 109 and lifts the same, thereby causing the pin 110 to project into the guide 95 and to force the hook 100 of the catch 98 against the action of the spring 101 into the path of the hook 105 of the pawl 104. The slide 94 is thus carried upward during the next upward movement of the cutter, and the paper strip fed in operative relation to said cutter.

After the binding medium has been deposited into the cap, the latter is advanced by the feeding strips, and stops in registering position with a circular opening 112 in the plate member 35, above which is disposed a burner 113, that is similar in construction to the one above mentioned. The exposed surface of the binding disk is heated thereby, this heating action resulting in a proper fusing of the exposed surface; the flame which is directed to the said surface by compressed air causing at the same time the binding medium to assume the shape of the inner surface of the cap.

The binding medium having been properly fused, the cap is advanced by the feed-

ing strips, and stops in registering position with a circular opening 114 in the plate member 35, where it receives a sealing disk or packing of cork or the like. The sealing disks are placed into a vertical tube 115, held upon the frame 80, said tube being provided with a longitudinal slot 116, through which a finger piece 117 of a weight 118 protrudes, said weight being placed on top of said sealing disks, and serves to feed them to a conveyer 119, which engages the lowermost of the disks in the tube and transports it into registering position with the circular opening 114. This opening tapers toward the plane of the top portion of the box 34, its upper diameter being larger than that of a sealing disk and its lower diameter being somewhat smaller than that of a disk. The purpose of this arrangement will be explained hereinafter. The conveyer 119 is made in the form of an oscillating plate, which is pivoted at 120 to the plate member 35, its acting end being provided with a notch 121, that is adapted to accommodate a sealing disk. The conveyer 119 is actuated by a lever 122, which is fulcrumed at 123 to the frame 80, and connected by a link 124 with said conveyer; said link being pivoted at 125 and 126 to the said lever and conveyer, respectively. The lever 122 is actuated by a slide 127, reciprocably disposed within a guide 128, the latter being formed upon the frame 80. This slide is provided with a cam 129, projecting through a slot 130 in said guide. The cam bears against the inclined face 131 of the lever 122, the latter being held in contact with said cam by springs 132, which are fastened to the said lever and the frame. The inclined face 131 of the lever is, preferably, formed by a blade spring 133, fastened to the lower end of the lever, and adapted to be adjusted by a set screw 134 to predetermine the swing of the lever. To the slide 127 is pivoted a spring pressed catch 135, which is in all respects identical in construction with the catch 98 above described, and adapted to cooperate with a pawl 136, carried by a slide 137, the latter two elements being similar in construction to the slide 102 and the pawl 104 above described. The slide 137 is attached to the arm 81 above described. A lever 138 is pivoted to the guide 128, said lever being similar to the lever 108 above described, its sleeve 139 being disposed in the opening 112. If a cap is located in the groove 36 in registering position with the opening 112, to be brought into registering position with the opening 114 at the next forward movement of the feeding strips, the lever 138 swings the catch 135 into the path of the pawl 136. The slide 127 will thus be carried upward by the arm 81 and actuate by means of its cam 129 by the intermediary of the lever 122 the conveyer 119, the latter transporting a sealing disk into registering position with the opening 114. The springs 132 return the conveyer and the parts cooperating therewith to their normal positions. Obviously, if there is no cap brought to the opening 112, the slide 127 is not lifted by the slide 137, and the conveyer 119 remains, therefore, stationary. The sealing disk is forced into the cap by an assembling plunger 140, which is reciprocably arranged in the frame 80 and attached to the arm 81. During the downward movement of the plunger 140, the disk is forced by said plunger through the tapering opening 114 into the cap. It should be noted that, since the diameter of the lower end of the opening 114 is smaller than that of a sealing disk, the latter will be compressed to some extent, and, when forced into the cap, will expand and be held thus firmly in the cap. The cap, when in registering position with the opening 114, rests upon a die 141 in the form of a screw bolt, its upper face 142 being concave, conforming thus to the shape of the outer face of the head of a cap.

The assembled crowns are advanced by the feeding strips to a uniting head 143, comprising a disk 144, keyed or otherwise attached to a vertical shaft 145. To this shaft is fixedly attached a worm gear 146, the teeth of which mesh with a worm 147, that is carried by the main driving shaft 32. With the disk 144 are made integral, or there may be attached thereto by means of spokes 148, two rings 149 and 150. These rings are disposed above the disk 144 a suitable distance from each other, as clearly shown in Fig. 2 of the drawings. A plurality of vertically disposed plungers 151 are slidably arranged in the rings 149 and 150, said plungers being located parallel to the shaft 145, and their lower ends being adapted to be forced by springs 152 into contact with the disk 144. The upper ends of the plungers, which project above the ring 150, are provided each with a peripheral recess 153, which is adapted to be engaged by a stationary cam 154, said cam being formed upon a plate 155, that is disposed in parallel relation to the ring 150 above the same. The cam is arranged in the path of the peripheral recesses of the plungers, whereby, as the uniting head rotates, said plungers will be raised by said cam, their springs lowering them as soon as disengaged from said cam. The cam raises a plunger before it arrives opposite to the feeding strips, and is disengaged from said plunger after it has left the said feeding strips. When a plunger arrives in registering position with the feeding strips, an assembled crown is placed upon the disk 144 beneath said plunger and, after the said plunger has been disengaged from the cam, its spring 152 will force the same

Page Tightly Bound

against the assembled crown cork, placing thereby the closure under compression and holding it in this condition until the closure makes nearly a full revolution around the shaft 145, when the plunger again arrives at the cam and is disengaged from the closure, allowing the latter to be guided by a projection 156 into a chute 157, to slide into a receptacle placed beneath the same. It is obvious that the binding material in the closure is still in its fused or softened condition when arriving upon the disk 144, so that this binding medium, due to the pressure, will firmly unite the parts of the closure, the binding medium being partly or wholly hardened when the closure is discharged into the chute.

It is obvious that the outer face of the cap is in no way affected by heat. The decoration thereon will, therefore, remain in its original state: furthermore both faces of the binding medium are properly fused with a result that a firm union is obtained between the parts of the closure.

The operation of the machine is obvious from the foregoing. It is to be noted that a simple and effective cap transporting mechanism is obtained, means being provided for preventing the advancing of the coated paper strip, the cutting and depositing of a binding disk and the feeding of a sealing disk in case caps are not brought in operative relation to the binding material depositing and sealing disk inserting elements of the machine.

What I claim is:—

1. In a machine for the manufacture of bottle closures of the cap variety, the combination with means for subjecting the inner face of the head of a metallic cap to heat, of means for inserting a binding material into the cap, means for applying heat directly to the exposed face of the binding material, means for depositing a sealing disk into the cap on top of the fused binding material, and means for conveying the cap in succession to each of the elements mentioned.

2. In a machine for the manufacture of bottle closures of the cap variety, the combination with means for subjecting the inner face of the head of a metallic cap to heat, of means for inserting a binding material into the cap, means for applying heat directly to the exposed face of the binding material, means for depositing a sealing disk into the cap on top of the fused binding material, means for holding the sealing disk under pressure within the cap after the parts are assembled and while the binding material is hardening, and means for conveying the cap in succession to each of the elements mentioned.

3. In a machine for the manufacture of bottle closures of the cap variety, the combination with transporting means for a metallic cap, of means for depositing a sealing disk into the cap, a conveyer for carrying the sealing disk to said depositing means, a swinging lever connected to said conveyer, a continuously reciprocating slide, a second slide, coacting means upon said two slides adapted to connect the same, whereby said slides are caused to move together, means upon said second slide for actuating, when moving in one direction, said lever, whereby said conveyer brings a sealing disk into registering position with said depositing means, and means coöperating with said connecting means upon said second slide and actuated by the caps upon said transporting means, whereby said last named connecting means is brought into operative position in relation to said connecting means upon said first slide when said transporting means brings a cap into registering position with said depositing means.

4. In a machine for the manufacture of bottle closures of the cap variety, the combination with transporting means for a metallic cap, of means for depositing a sealing disk into the cap, a conveyer for carrying the sealing disk to said depositing means, a swinging lever connected to said conveyer, a continuously reciprocating slide, a second slide, a pawl upon said first slide, a catch upon said second slide adapted to coact with said pawl so as to connect said two slides, whereby they are caused to move together, means upon said second slide for actuating, when moving in one direction, said lever, whereby said conveyer brings a sealing disk into registering position with said depositing means, and means coöperating with said catch and actuated by the caps upon said transporting means, whereby said catch is brought into operative position in relation to said pawl when said transporting means brings a cap into registering position with said depositing means.

5. In a machine for the manufacture of bottle closures of the cap variety, the combination with transporting means for a metallic cap, of means for cutting a disk from a strip of binding material and inserting it into the cap, a roller for feeding the strip to said cutting means, a clutch connected with said roller, a continuously reciprocating slide, a second slide, coacting means upon said two slides adapted to connect the same, whereby said slides are caused to move together, means upon said second slide for rendering, when moving in one direction, said clutch operative, whereby said roller advances the strip of binding material toward said cutting means, and means coöperating with said connecting means upon said second slide and actuated by the caps upon said transporting means, whereby said last named connecting means is brought into

perative position in relation to said connecting means upon said first slide when said transporting means brings a cap into registering position with said inserting means.

6. In a machine for the manufacture of bottle closures of the cap variety, the combination with transporting means for a metallic cap, of means for cutting a disk from a strip of binding material and inserting it into the cap, a roller for feeding the strip to said cutting means, a clutch connected with said roller, a continuously reciprocating slide, a second slide, a pawl upon said first slide, a catch upon said second slide adapted to coact with said pawl so as to connect said two slides, whereby they are caused to move together, means upon said second slide for rendering, when moving in one direction, said clutch operative, whereby said roller advances the strip of binding material toward said cutting means, and means cooperating with said catch and actuated by the caps upon said transporting means, whereby said catch is brought into operative relation to said pawl when said transporting means brings a cap into registering position with said inserting means.

UNITED STATES PATENT OFFICE.

ALEXANDER BOGDÁNFFY, OF NEW YORK, N. Y., ASSIGNOR TO INTERNATIONAL CORK COMPANY, OF BROOKLYN, NEW YORK, A CORPORATION OF NEW YORK.

MACHINE FOR THE MANUFACTURE OF BOTTLE-CLOSURES.

1,053,565. Specification of Letters Patent. Patented Feb. 18, 1913.

Application filed May 27, 1911. Serial No. 629,871.

To all whom it may concern:

Be it known that I, ALEXANDER BOGDÁNFFY, a subject of the King of Hungary, and resident of the city of New York, in the county of Kings and State of New York, have invented certain new and useful Improvements in Machines for the Manufacture of Bottle-Closures, of which the following is a specification.

The present invention relates to machines for the manufacture of bottle closures of the class known as "crown cork sealing caps or closures". Closures of this type comprise usually three parts, that is a metallic cap or crown, having a corrugated flange to be locked to the exterior of the bottle neck, a sealing disk or packing of cork or the like, and a disk of impervious binding material interposed between the metallic cap and the cork disk. These caps have been manufactured heretofore in the following manner: The three parts mentioned are assembled and the closure, as a whole, is then subjected to heating action, whereby the interposed impervious binding material is softened or fused so that, when pressure is applied to the closure, the impervious binding medium will firmly unite the packing disk with the metallic cap or crown. This process of manufacture has, however, several defects, to wit: The packing disks are liable to be injured by the heating action, no matter whether they are of cork or of a composite type. If cork sealing disks are employed, they will lose to some degree their toughness, or in other words they will become brittle, whereby the sealing properties of the same will be impaired to a great degree. If, on the other hand, sealing disks of a composite type are used, they might be rendered entirely useless for the reason that they contain a fusible material, which is, of course, affected by the heat. Another defect of the process of manufacture hereinbefore mentioned consists in that, when the parts are assembled, the diameter of the metallic cap is slightly reduced so as to grip the sealing disk. When now, after the assembling, the closure is heated, the moisture and air between the members of the closure cannot escape. Moreover, when then the parts are subjected to heating action, the air will be expanded and act as a cushion, as it were, when the closure is subjected to pressure, and thus prevent a firm union between the parts thereof.

The object of the present invention is to obviate these defects mentioned, and with this and other objects in view, which will appear as the nature of the invention is better understood, the same consists in the combination, arrangement and construction of parts hereinafter fully described, pointed out in the appended claims and illustrated in the accompanying drawings, it being understood that many changes may be made in the size and proportion of the several parts and details of construction without departing from the spirit or sacrificing any of the advantages of the invention.

One of the many possible embodiments of the invention is illustrated in the accompanying drawings, in which:—

Figure 1 is a plan view of a device constructed in accordance with the present invention; Fig. 2 is a front elevation thereof; Fig. 3 is a sectional view of a metallic cap inverted or in the position in which it passes to the machine ready to receive the other parts of the composite sealing closure; Fig. 4 is a plan view of the sealing disk of the closure; Fig. 5 is a front elevation thereof; Fig. 6 is a plan view of an impervious binding disk which is inserted into the metallic cap; Fig. 7 is a front elevation thereof; Fig. 8 is a sectional view of the means for feeding the strip of paper from which the binding disks are cut out; Fig. 9 is a front elevation of the device shown in Fig. 8; Fig. 10 is a vertical section taken through the means for cutting the strip of paper; Fig. 11 is a vertical section taken through the sealing disk holding means; Fig. 12 is a side elevation, partly in section, of the means for forcing the sealing disk into the metal cap; Fig. 13 is a sectional view of the means for conveying the sealing disk to the metallic cap; Fig. 14 is a detail view of a worm for intermittently rotating the transporting means of the device; Fig. 15 is a plan view of a transporting wheel; Fig. 16 is a detail of construction of the pressure applying means of the apparatus; and Fig. 17 is a side elevation, partly in section, of a further detail of construction.

In the drawings, the numeral 20 indicates a horizontal table, which is supported by legs or standards 21, the latter being at-

tached in any suitable manner to the floor. Above the plane of the table 20 is arranged a substantially horizontal support 23 onto which the metallic caps are placed in their inverted positions, to be passed manually to a continuously rotating carrying disk 24, which conveys the caps, one after the other, along a channel 25 in the direction of the arrow indicated in Fig. 1 of the drawings, which channel is formed between the said carrying disk 24 and a cover plate 26. This cover plate is attached to the table 20 in any suitable manner. The carrying disk 24 feeds the inverted caps or crowns one after the other to the recesses 27 of a star wheel 28, which is attached to a vertical shaft 29, journaled in the table 20 and in a bearing 30. To this shaft intermittent rotary motion is imparted in the direction of the arrow by means which will be hereinafter described. The star wheel 28 overlies partly the carrying disk 24, engages the flange portions 31 of the caps 32, and conveys them along a groove 33′ in the table 20 to rest directly beneath the means which cuts the impervious binding disk 33 from a strip of suitably prepared paper or other material, and places the disk into the inverted cap.

The paper strip, from which the disks 33 are cut, is wound upon a reel 34, which is suitably journaled in the frame of the machine, and from which the strip is conducted into a guide 35 to pass between the feeding rollers 36 and 37. The feeding roller 36 is journaled in the frame of the machine and projects through a slot 38 in the guide 35 above the lower plane of the latter, while the spindle 39 of the roller 37 is journaled in a bearing 40, and carries at its outer end a bevel gear 41, meshing with a similar gear 42, upon the shaft 43, upon the opposite end of which is mounted another bevel gear 44 in mesh with a similar gear 45, which latter is attached to the shaft 29 of the star wheel 28. It will be observed that the feeding rollers 36 and 37 will thus rotate intermittently, and advance the paper strip to the cutting means 46. The cutting means comprises a tubular cutter 47, secured in any suitable manner to an arm 48, which is slidably arranged in a vertical guideway 49 of a bracket 50, attached to the table 20. The arm 48 is pivotally engaged by a rod 51, which is fastened to the strap of an eccentric 52, the latter being mounted upon the main driving shaft 53 of the machine. The driving shaft is journaled in bearings, which are secured to or made integral with the standards or legs 21. As the paper disk is cut from the strip, it will be automatically forced, upon the upward movement of the cutter 47, by a stem 54 through a hole 55 in the guide 35 into the metallic cap. The stem 54 projects through an opening 56 of the arm 48 above the plane of said arm and carries upon its upper end a weight 57. When therefore the cutter 47 moves upward the weight 57 will force the stem 54 downward and thereby the paper disk into the cap. After this, upon the further upward movement of the arm 48, the latter will engage the weight 57 and lift thus the stem 54 out of the hole 55 in the guide 35. The paper disk having been deposited in the metal cap, the latter will be transported by the wheel 28 within the reach of a star wheel 58, which rotates in a direction opposite to that of the star wheel 28 and lies in a plane below that of the wheel 28, engaging thus the heads 59 of the metal caps 32. The star wheel 58 is mounted upon a shaft 60, which is suitably journaled in the frame and in a bearing 61. The caps and paper disks are by the wheel 58 brought within the reach of a third star wheel 62. This star wheel overlies partly the wheel 58 and engages the metal caps at their flange portions 31, transporting the same intermittently to the means which force the sealing disks into the caps. The star wheel 62 is attached to a shaft 63, mounted in the frame of the machine and in a bearing 64. This shaft moves also intermittently, and is actuated also from the main driving shaft 53 in a manner hereinafter to be specified.

While being transported by the wheel 62, the caps and the binding disks therein are heated by a suitable heating means, for instance a gas heater 65. This heater comprises a perforated tubular member 66, connected with the gas supply pipe 67, the communication being controlled by a valve 68. The heater is, preferably, arranged below the table 20. The heat is transmitted to the binding disks by the metal caps directly in contact with the table. The binding material is thus fused or softened for the purpose of uniting the sealing disk to the cap, and for other well known purposes. After heating, the caps are transported by the wheel 62 to an assembling plunger 69, attached to an arm 70, which is slidably arranged in a vertical guide 71 of a bracket 72. The arm 70 is pivotally connected with a rod 73, which is fastened to the strap of an eccentric 74, the latter being keyed to the main driving shaft 53. The sealing disks are placed into a substantially vertical tube 75, which is attached to the table 20 by means of a bracket 76 or otherwise, and is provided with a longitudinal slot 77 through which a finger piece 78 of a weight 79 protrudes, said weight being placed on the sealing disks, and serves to feed the said disks into a guideway 80 of a plate member 81, which is attached to the table by a bracket 82′ in a plane above the plane of the star wheel 62. The plate 81 is provided with an aperture 82 in alinement with the plunger 69. This aperture tapers toward the plane

of the wheel 62, its upper diameter being larger than the diameter of a sealing disk 83, and the diameter at its lower end being somewhat smaller than that of a sealing disk. The purpose of this arrangement will be explained presently. The sealing disks are conveyed in the guideway 80 from below the tubular member 75 to the aperture 82 by a reciprocatable conveyer 84, which is slidably arranged in the guideway 80, and connected by a plurality of links and rods 85, 85 with the strap of an eccentric 86, which is keyed to the main driving shaft 53 of the machine. The conveyer 84 is provided with a recess 86′, which engages the sealing disk in transferring the same to the aperture 82. Obviously the angular relation of the eccentrics 74 and 86 must be such that when the plunger 69 is lifted, the conveyer 84 will move inward and transfer thereby a sealing disk within the reach of the plunger 69, which, in its downward movement, will force the cork disk through the aperture 82 into the metal cap. It should be noted that since the diameter of the lower end of the aperture 82 is smaller than that of the sealing disk, the latter will be compressed to some extent and, when forced into the cap, will expand and be held thus firmly in the cap.

As it happens sometimes that one or the other of the recesses in the star wheel 62 does not contain a metal cap, it becomes necessary to eject the sealing disk from that recess after it has passed the plunger 69. For this purpose the plunger 69 carries a bracket 88, to which a downwardly extending tubular member 89 is attached, in which is slidably arranged a spindle 90, provided upon its upper end with a stop 91 and near to its lower end with a disk 92. Against this disk and the bracket 88 bears a spring 93, tending to force the spindle 90 downward into the recesses of the star wheel 62. The distance between the longitudinal axes of the plunger 69 and the spindle 90 is equal to the distance between two neighboring recesses in the star wheel 62. When therefore the plunger 69 is forced downward to press a sealing disk into the metal cap beneath it, the spindle 90 will be forced into the neighboring recess of the star wheel. If an assembled crown cork is in this recess, the spring 93 will be compressed by the upward movement of the spindle 90. If, however, only a sealing disk is seated in the recess, the spindle 90 will force the same through an opening 94 in the table into a receptacle below said opening, for the reason that the tension of the spring 93 is greater than the resistance offered by the sealing disk in the recess.

The assembled crowns slide down an inclined passage 95 to the uniting head 96. This head comprises a rotary drum 97, keyed to a shaft 98, which is continuously driven from the main driving shaft 53. The drum is provided with a plurality of peripheral recesses 99, which are adapted to receive, one after the other, assembled crown corks from the passage 95. Plungers 100 are slidably arranged in the drum in alinement with the recesses, said plungers being located parallel with the longitudinal axis of the drum, and provided at their outer forked ends each with a pin 101, which engages slots 102 in radial arms 103, the inner ends of which are pivoted at 104 to the hub of the drum, while their upper free ends carry rollers 105, which are adapted to coact with a cam 106, attached to the frame of the machine. The arms 103 are engaged by the pointed ends 107 of spring pressed pins 108, which are slidably mounted on a ring 109, attached to the shaft 98. The cam 106 is arranged in the path of the rollers 105, whereby, as the drum 97 rotates, the plungers 100 will be forced against the action of the springs 110 upon the pins 108 out of the recesses 99 in the drum before they arrive opposite to the passage 95. When a recess arrives at this point, a crown cork will slide into the same, and after the corresponding roller 105 is disengaged from the cam, the spring 110 will force the plunger against the assembled crown cork, placing thereby the parts of the closure under compression, and holding it in this condition until the closure makes very nearly a full revolution around the shaft 98, when the roller of the plunger again arrives at the cam 106, whereby the plunger is disengaged from the closure, allowing the closure to be guided by a projection 111 into a chute 111′. It is obvious that the binding disk in the closure is still in its fused or softened condition when arriving in a recess of the drum 97, so that this binding medium, due to the pressure, will firmly unite the parts of the closure, the binding medium being partly or wholly hardened when the closure is discharged into the chute 111′. It is to be noted that an intimate union is formed between the sealing disk and the metal cap as there is no air between the said two parts to prevent such union. The sealing disk, on the other hand, is in its original tough condition, as it has not been subjected to the influence of the heating means upon the machine.

A tongue 112 is pivoted at 113 to a stationary part of the frame, its free end being provided with a pin 114, engaging an arc-shaped slot 115 in the frame. A spring 116 forces the tongue 112 into contact with the drum, so that closures, which are not properly seated in their recesses, will be forced into the same before the plunger engages them.

Motion is imparted to the entire mechanism through the intermediary of a pulley

117, which is keyed to the main driving shaft 53. The shaft 24′ of the continuously rotating disk 24 is driven by a belt 118, running over pulleys 119 and 120, attached to the shafts 24′ and 53, respectively. The shafts 29 and 63 are driven by worms 120′, 120′ upon the main driving shaft 53, engaging worm gears 121, 121 upon the shafts 29 and 63. The worms 120′, 120′ have straight portions 122, and while these are engaging the worm gears 121, 121, the latter are at rest. When the inclined portions 123, 123 of the worms 120′ coact with a tooth of the worm gears the same will be rotated a given distance, whereby the star wheels will transport the crowns a corresponding distance. The star wheel 58 may be either driven continuously from the shaft 53, or driven by the star wheel 62 through the intermediary of the metal caps engaged by both wheels. The shaft 98 is also actuated from the main shaft 53. For this purpose a bevel gear 125 is mounted upon the shaft 98 and meshes with a similar gear 126, keyed to a shaft 127, which is journaled in a bearing 128. Upon the shaft 127 is furthermore mounted a spur gear 129, meshing with a similar gear 130, the latter being fixedly attached to the shaft 53.

What I claim is:—

1. In a machine for the manufacture of bottle closures of the cap variety, the combination with means for placing a disk of impervious binding material into a cap, of means for depositing a sealing disk into the cap on top of the binding material, heating means interposed between said sealing disk depositing means and said means which place the binding disk into the cap, and means for holding the sealing disk under pressure within the cap after the parts are assembled and while the binding material is hardening.

2. In a machine for the manufacture of bottle closures of the cap variety, the combination with means for placing a disk of impervious binding material into a cap, of means for depositing a sealing disk into the cap on top of the binding material, heating means interposed between said sealing disk depositing means and said means which place the impervious binding disk into the cap, a rotary drum having a plurality of recesses into which the assembled closures are fed, and a plurality of spring pressed plungers for holding the sealing disks under pressure within the caps in said recesses while the binding material is hardening.

3. In a machine for the manufacture of bottle closures of the cap variety, the combination with means for placing an impervious fusible binding material into a cap, of means for depositing a sealing disk into the cap on top of the binding material, heating means interposed between said sealing disk depositing means and said means which place the impervious binding material into the cap, and means for holding the sealing disk under pressure within the cap after the parts are assembled and while the binding material is hardening.

4. In a machine for the manufacture of bottle closures of the cap variety, the combination with means for cutting disks from a strip of impervious binding material and forcing a disk into a cap, of means for depositing a sealing disk into the cap on top of the binding material, heating means interposed between said cutting means and sealing disk depositing means, and means for holding the sealing disk under pressure within the cap after the parts are assembled and while the binding material is hardening.

5. In a machine for the manufacture of bottle closures of the cap variety, the combination with means for cutting disks from a strip of impervious binding material and forcing a disk into a cap, of means for depositing a sealing disk into the cap on top of the binding material, heating means interposed between said cutting means and sealing disk depositing means, a rotary drum having a plurality of recesses into which the assembled closures are fed, and a plurality of spring pressed plungers for holding the sealing disks under pressure within the caps in said recesses while the binding material is hardening.

6. In a machine for the manufacture of bottle closures of the cap variety, the combination with means for cutting disks from a strip of impervious binding material and forcing a disk into the metallic cap, of means for depositing a sealing disk into the cap on top of the binding material, heating means inserted between said cutting means and sealing disk depositing means, a rotary drum having a plurality of recesses into which the assembled closures are automatically fed, and a plurality of spring pressed plungers for holding the sealing disks under pressure within the caps in said recesses while the binding material is hardening.

7. In a machine for the manufacture of bottle closures of the cap variety, the combination with a rotary drum having a plurality of peripheral recesses, of means for feeding an assembled closure into each of said recesses, plungers slidably arranged in said drum in alinement with said recesses having fork shaped ends, radial arms pivoted to said drum corresponding in number to said plungers engaging the fork shaped ends of said plungers and projecting above the plane of the same, yielding connections between said plungers and radial arms, spring pressed pins engaging said radial arms for applying pressure to the closures in the recesses to unite the parts thereof, rollers carried by the free ends of

said arms, and a cam in the path of said rollers for forcing said plungers away from said recesses before they arrive opposite to said feeding means.

8. In a machine for the manufacture of bottle closures of the cap variety, the combination with a rotary drum having a plurality of peripheral recesses, of means for feeding an assembled closure into each of said recesses, plungers slidably arranged in said drum in alinement with said recesses having fork shaped ends, radial arms pivoted to said drum corresponding in number to said plungers engaging the fork shaped ends of said plungers and projecting above the plane of the same, yielding connections between said plungers and said arms, spring pressed pins engaging said radial arms for applying pressure to the closures in the recesses to unite the parts thereof, rollers carried by the free ends of said arms, and a stationary cam in the path of said rollers for forcing said plungers away from said recesses before they arrive opposite to said feeding means.

9. In a machine of the character set forth, in combination, means for inserting a cementing material in a cap, means for heating and fusing said material while in said cap, means for registering a sealing gasket with said cap, means for forcing said gasket into contact with said fused cementing material, and means for maintaining said contact until said cementing material is set.

Signed at New York, in the county of New York and State of New York this 18th day of May, A. D. 1911.

UNITED STATES PATENT OFFICE.

ALEXANDER BOGDÁNFFY, OF NEW YORK, N. Y., ASSIGNOR TO INTERNATIONAL CORK COMPANY, OF BROOKLYN, NEW YORK, A CORPORATION OF NEW YORK.

PROCESS OF MANUFACTURING BOTTLE-CLOSURES.

1,053,898. Specification of Letters Patent. Patented Feb. 18, 1913.

Original application filed May 27, 1911, Serial No. 629,871. Divided and this application filed September 8, 1911, Serial No. 648,502. Renewed August 7, 1912. Serial No. 713,942.

To all whom it may concern:

Be it known that I, ALEXANDER BOGDÁNFFY, a subject of the King of Hungary, and resident of the city of New York, in the county of Kings and State of New York, have invented certain new and useful Improvements in Processes of Manufacturing Bottle-Closures, of which the following is a specification, the same being a division of application Serial No. 629,871, filed May 27, 1911.

The present invention relates to a process for the manufacture of bottle closures of the class known as "crown cork sealing caps or closures." Closures of this type comprise usually three parts, that is a metallic cap or crown, having a corrugated flange to be locked to the exterior of the bottle neck, a sealing disk or packing of cork or the like, and a disk of impervious binding material interposed between the metallic cap and the cork disk. These caps have been manufactured heretofore in the following manner: The three parts mentioned are assembled and the closure, as a whole, is then subjected to heating action, whereby the interposed impervious binding material is softened or fused so that, when pressure is applied to the closure, the impervious binding medium will firmly unite the packing disk with the metallic cap or crown. This process of manufacture has, however, several defects, to wit: The packing disks are liable to be injured by the heating action, no matter whether they are of cork or of a composite type. If cork sealing disks are employed, they will lose to some degree their toughness, or in other words they will become brittle, whereby the sealing properties of the same will be impaired to a great degree. If, on the other hand, sealing disks of a composite type are used, they might be rendered entirely useless for the reason that they contain a fusible material, which is, of course, affected by the heat. Another defect of the process of manufacture hereinbefore mentioned consists in that, when the parts are assembled, the diameter of the metallic cap is slightly reduced so as to grip the sealing disk. When now, after the assembling, the closure is heated, the moisture and air between the members of the closure cannot escape. Moreover, when then the parts are subjected to heating action, the air will be expended and act as a cushion, as it were, when the closure is subjected to pressure, and thus prevent a firm union between the parts thereof.

The object of the present invention is to obviate these defects mentioned, and with this and other objects in view, which will appear as the nature of the invention is better understood, the same consists in the process hereinafter fully described, and pointed out in the appended claim.

One of the many possible apparatus for carrying out the process forming the subject of the present application for Letters Patent is illustrated in the accompanying drawings, in which:—

Figure 1 is a plan view of a device constructed in accordance with the present invention; Fig. 2 is a front elevation thereof; Fig. 3 is a sectional view of a metallic cap inverted or in the position in which it passes to the machine ready to receive the other parts of the composite sealing closure; Fig. 4 is a plan view of the sealing disk of the closure; Fig. 5 is a front elevation thereof; Fig. 6 is a plan view of an impervious binding disk which is inserted into the metallic cap; Fig. 7 is a front elevation thereof; Fig. 8 is a sectional view of the means for feeding the strip of paper from which the binding disks are cut out; Fig. 9 is a front elevation of the device shown in Fig. 8; Fig. 10 is a vertical section taken through the means for cutting the strip of paper; Fig. 11 is a vertical section taken through the sealing disk holding means; Fig. 12 is a side elevation, partly in section, of the means for forcing the sealing disk into the metal cap; Fig. 13 is a sectional view of the means for conveying the sealing disk to the metallic cap; Fig. 14 is a detail view of a worm for intermittently rotating the transporting means of the device; Fig. 15 is a plan view of a transporting wheel; Fig. 16 is a detail of construction of the pressure applying means of the apparatus; and Fig. 17 is a side elevation of a further detail of construction.

In the drawings, the numeral 20 indicates a horizontal table, which is supported by legs or standards 21, the latter being attached in any suitable manner to the floor. Above

Page Tightly Bound

the plane of the table 20 is arranged a substantially horizontal support 23 onto which the metallic caps are placed in their inverted positions, to be passed manually to a continuously rotating carrying disk 24, which conveys the caps, one after the other, along a channel 25 in the direction of the arrow indicated in Fig. 1 of the drawings, which channel is formed between the said carrying disk 24 and a cover plate 26. This cover plate is attached to the table 20 in any suitable manner. The carrying disk 24 feeds the inverted caps or crowns one after the other to the recesses 27 of a star wheel 28, which is attached to a vertical shaft 29, journaled in the table 20 and in a bearing 30. To this shaft intermittent rotary motion is imparted in the direction of the arrow by means which will be hereinafter described. The star wheel 28 overlies partly the carrying disk 24, engages the flange portions 31 of the caps 32, and conveys them along a groove 33′ in the table 20 to rest directly beneath the means which cuts the impervious binding disk 33 from a strip of suitably prepared paper or other material, and places the disk into the inverted cap.

The paper strip, from which the disks 33 are cut, is wound upon a reel 34, which is suitably journaled in the frame of the machine, and from which the strip is conducted into a guide 35 to pass between the feeding rollers 36 and 37. The feeding roller 36 is journaled in the frame of the machine and projects through a slot 38 in the guide 35 above the lower plane of the latter, while the spindle 39 of the roller 37 is journaled in a bearing 40, and carries at its outer end a bevel gear 41, meshing with a similar gear 42 upon the shaft 43, upon the opposite end of which is mounted another bevel gear 44 in mesh with a similar gear 45, which latter is attached to the shaft 29 of the star wheel 28. It will be observed that the feeding rollers 36 and 37 will thus rotate intermittently, and advance the paper strip to the cutting means 46. The cutting means comprises a tubular cutter 47, secured in any suitable manner to an arm 48, which is slidably arranged in a vertical guideway 49 of a bracket 50, attached to the table 20. The arm 48 is pivotally engaged by a rod 51, which is fastened to the strap of an eccentric 52, the latter being mounted upon the main driving shaft 53 of the machine. The driving shaft is journaled in bearings, which are secured to or made integral with the standards or legs 21. As the paper disk is cut from the strip, it will be automatically forced, upon the upward movement of the cutter 47, by a stem 54 through a hole 55 in the guide 35 into the metallic cap. The stem 54 projects through an opening 56 of the arm 48 above the plane of said arm and carries upon its upper end a weight 57. When therefore the cutter 47 moves upward, the weight 57 will force the stem 54 downward and thereby the paper disk into the cap. After this, upon the further upward movement of the arm 48, the latter will engage the weight 57 and lift thus the stem 54 out of the hole 55 in the guide 35. The paper disk having been deposited in the metal cap, the latter will be transported by the wheel 28 within the reach of a star wheel 58, which rotates in a direction opposite to that of the star wheel 28 and lies in a plane below that of the wheel 28, engaging thus the heads 59 of the metal caps 32. The star wheel 58 is mounted upon a shaft 60, which is suitably journaled in the frame and in a bearing 61. The caps and paper disks are by the wheel 58 brought within the reach of a third star wheel 62. This star wheel overlies partly the wheel 58 and engages the metal caps at their flange portions 31, transporting the same intermittently to the means which force the sealing disks into the caps. The star wheel 62 is attached to a shaft 63, mounted in the frame of the machine and in a bearing 64. This shaft moves also intermittently, and is actuated also from the main driving shaft 53 in a manner hereinafter to be specified. While being transported by the wheel 62, the caps and the binding disks therein are heated by a suitable heating means, for instance a gas heater 65. This heater comprises a perforated tubular member 66, connected with the gas supply pipe 67, the communication being controlled by a valve 68. This heater is, preferably, arranged below the table 20. The heat is transmitted to the binding disks by the metal caps directly in contact with the table. The binding material is thus fused or softened for the purpose of uniting the sealing disk to the cap, and for other well known purposes. After heating, the caps are transported by the wheel 62 to an assembling plunger 69, attached to an arm 70, which is slidably arranged in a vertical guide 71 of a bracket 72. The arm 70 is pivotally connected with a rod 73, which is fastened to the strap of an eccentric 74, the latter being keyed to the main driving shaft 53. The sealing disks are placed into a substantially vertical tube 75, which is attached to the table 20 by means of a bracket 76 or otherwise, and is provided with a longitudinal slot 77 through which a finger piece 78 of a weight 79 protrudes, said weight being placed on the sealing disks, and serves to feed the said disks into a guideway 80 of a plate member 81, which is attached to the table by a bracket 82′ in a plane above the plane of the star wheel 62. The plate 81 is provided with an aperture 82 in alinement with the plunger 69. This aperture tapers toward the plane of the wheel 62, its upper diameter being larger than the diameter of a sealing disk 83, and the diameter at its

lower end being somewhat smaller than that of a sealing disk. The purpose of this arrangement will be explained presently. The sealing disks are conveyed in the guideway 80 from below the tubular member 75 to the aperture 82 by a reciprocatable conveyer 84, which is slidably arranged in the guideway 80, and connected by a plurality of links and rods 85, 85 with the strap of an eccentric 86, which is keyed to the main driving shaft 53 of the machine. The conveyer 84 is provided with a recess 86', which engages the sealing disk in transferring the same to the aperture 82. Obviously the angular relation of the eccentrics 74 and 86 must be such that when the plunger 69 is lifted, the conveyer 84 will move inward and transfer thereby a sealing disk within the reach of the plunger 69, which, in its downward movement, will force the cork disk through the aperture 82 into the metal cap. It should be noted that since the diameter of the lower end of the aperture 82 is smaller than that of the sealing disk, the latter will be compressed to some extent and, when forced into the cap, will expand and be held thus firmly in the cap.

As it happens sometimes that one or the other of the recesses in the star wheel 62 does not contain a metal cap, it becomes necessary to eject the sealing disk from that recess after it has passed the plunger 69. For this purpose the plunger 69 carries a bracket 88, to which a downwardly extending tubular member 89 is attached, in which is slidably arranged a spindle 90, provided upon its upper end with a stop 91 and near to its lower end with a disk 92. Against this disk and the bracket 88 bears a spring 93, tending to force the spindle 90 downward into the recesses of the star wheel 62. The distance between the longitudinal axes of the plunger 69 and the spindle 90 is equal to the distance between two neighboring recesses in the star wheel 62. When therefore the plunger 69 is forced downward to press a sealing disk into the metal cap beneath it, the spindle 90 will be forced into the neighboring recess of the star wheel. If an assembled crown cork is in this recess, the spring 93 will be compressed by the upward movement of the spindle 90. If, however, only a sealing disk is seated in the recess, the spindle 90 will force the same through an opening 94 in the table into a receptacle below, said opening, for the reason that the tension of the spring 93 is greater than the resistance offered by the sealing disk in the recess.

The assembled crowns slide down an inclined passage 95 to the uniting head 96. This head comprises a rotary drum 97, keyed to a shaft 98, which is continuously driven from the main driving shaft 53. The drum is provided with a plurality of peripheral recesses 99, which are adapted to receive, one after the other, assembled crown corks from the passage 95. Plungers 100 are slidably arranged in the drum in alinement with the recesses, said plungers being located parallel with the longitudinal axis of the drum, and provided at their outer forked ends each with a pin 101, which engages slots 102 in radial arms 103, the inner ends of which are pivoted at 104 to the hub of the drum, while their upper free ends carry rollers 105, which are adapted to coact with a cam 106, attached to the frame of the machine. The arms 103 are engaged by the pointed ends 107 of spring pressed pins 108, which are slidably mounted on a ring 109, attached to the shaft 98. The cam 106 is arranged in the path of the rollers 105, whereby, as the drum 97 rotates, the plungers 100 will be forced against the action of the springs 110 upon the pins 108 out of the recesses 99 in the drum before they arrive opposite to the passage 95. When a recess arrives at this point, a crown cork will slide into the same, and after the corresponding roller 105 is disengaged from the cam, the spring 110 will force the plunger against the assembled crown cork, placing thereby the parts of the closure under compression, and holding it in this condition until the closure makes very nearly a full revolution around the shaft 98, when the roller of the plunger again arrives at the cam 106, whereby the plunger is disengaged from the closure, allowing the closure to be guided by a projection 111 into a chute 111'. It is obvious that the binding disk in the closure is still in its fused or softened condition when arriving in a recess of the drum 97, so that this binding medium, due to the pressure, will firmly unite the parts of the closure, the binding medium being partly or wholly hardened when the closure is discharged into the chute 111'. It is to be noted that an intimate union is formed between the sealing disk and the metal cap as there is no air between the said two parts to prevent such union. The sealing disk, on the other hand, is in its original tough condition, as it has not been subjected to the influence of the heating means upon the machine. A tongue 112 is pivoted at 113 to a stationary part of the frame, its free end being provided with a pin 114, engaging an arc-shaped slot 115 in the frame. A spring 116 forces the tongue 112 into contact with the drum, so that closures, which are not properly seated in their recesses, will be forced into the same before the plunger engages them.

Motion is imparted to the entire mechanism through the intermediary of a pulley 117, which is keyed to the main driving shaft 53. The shaft 24' of the continuously

rotating disk 24 is driven by a belt 118, running over pulleys 119 and 120, attached to the shafts 24′ and 53, respectively. The shafts 29 and 63 are driven by worms 120′, 120′ upon the main driving shaft 53, engaging worm gears 121, 121 upon the shafts 29 and 63. The worms 120′ have straight portions 122, and while these are engaging the worm gears 121, 121, the latter are at rest. When the inclined portions 123 of the worms 120′ coact with a tooth of the worm gears, the same will be rotated a given distance, whereby the star wheels will transport the crowns a corresponding distance. The star wheel 58 may be either driven continuously from the shaft 53, or driven by the star wheel 62 through the intermediary of the metal caps engaged by both wheels. The shaft 98 is rotated also from the main shaft 53, the connection between these two shafts has, however, not been shown, as it would complicate too much the drawing.

What I claim is:—

In a process for the manufacture of bottle closures of the cap variety, which consists, first, in placing a fusible binding medium into the metallic cap, second, heating the metallic cap and binding medium for properly fusing the latter, third, depositing a sealing disk into the cap on top of the fused binding medium, and, fourth, subjecting the assembled closure to pressure while the binding material is hardening.

Signed at New York, in the county of New York and State of New York, this 28th day of July, A. D. 1911.

BOTTLE-SEALING DEVICE.

SPECIFICATION forming part of Letters Patent No. 468,226, dated February 2, 1892.

Application filed May 19, 1891. Serial No. 393,293. (No model.)

To all whom it may concern:

Be it known that I, WILLIAM PAINTER, of the city of Baltimore, in the State of Maryland, have invented certain new and useful Improvements in Bottle-Sealing Devices; and I do hereby declare that the following specification, taken in connection with the drawings furnished and forming a part of the same, is a clear, true, and complete description of the several features of my invention.

My present invention pertains to the sealing of bottles by the use of compressible packing-disks and metallic caps, which have flanges bent into reliable locking engagement with annular locking-shoulders on the heads of bottles, while the packing-disk is in each case under heavy compression and in enveloping contact with the lip of the bottle.

In order that the status of my present improvements may be properly defined with respect of novelty and utility, I deem it proper to briefly review the prior art in this special connection. So far as my knowledge extends, I am the first to seal bottles by means of sealing-disks each compressed into close solid contact with the lip of the bottle and maintained in that condition by means of a flanged metallic sealing-cap, the flange of which is bent or crimped into locking contact (while the disk is under pressure) with an appropriate annular locking-shoulder on the head of the bottle, as well as the first to devise methods and means by which in the use of such caps and disks liquids can be bottled under even the highest gaseous pressures employed in this art. Disclosures of my several prior inventions in this line have been made by me in certain of my applications for patents heretofore filed. (See Serial Nos. 323,314 and 355,603.)

Inasmuch as the application of my sealing-caps involves powerful mechanism for compressing the disks and for bending or crimping the flanges of the caps into locking contact with bottles, it follows that considerable manual force must be applied for detaching the caps from the bottles, and therefore in the early stages of my invention the use of loops of some kind or of equivalent holes in the tops of the caps was deemed essential, and the caps had wide or deep pendent flanges and they contained sealing-disks of considerable bulk or thickness. During further progressive stages of my invention I demonstrated the economic importance of using thin disks, and these in some forms preclude the use of a cap having either a hole in its top or even some forms of inserted loops. These contingencies led, after much devising and experimenting, to the production of a cap without a loop or a hole in its top, a thinner disk, and consequently narrower flanges, thus substantially reducing the cost of the sealing device as a whole without decreasing, but in fact increasing, the efficiency of the applied cap, and also securing higher sealing efficiency by the use of a less expensive disk. The flange of the cap being narrow and its locking or bent portions being between the edge of the flange and the top of the cap, and the said edge being practically intact or continuous the cap could be applied to a bottle with a tenacity at least equal to, if not greater than, the caps having wider and consequently more flexible flanges, and hence as much or more manual force was required for detaching said caps than with those of the said previous forms. These improved caps having in themselves no special provision—such as loops or openings in their tops—for detaching them from bottles led to my further devising a novel method of their combination with the bottle, in accordance with which the pendent edge of the flange below the bent portion is so far projected from the adjacent surface of the bottle-head as to afford an engaging-shoulder, to which a bottle-opener could be readily applied; but the required manual force to remove the cap was so great that openers of special form were a necessity, and these were operated by leverage and were fulcrumed either upon the top surface of the cap or upon the outwardly-rounded surface of the bottle-head below the cap. The disadvantages to consumers incident to a positive requirement for the use of specially-constructed openers are obvious, and to avoid them I have now so devised my loopless and close-topped caps and have so organized a combination thereof with the bottles that the caps can be almost as readily detached by the use of a knife, a screw-driver, a nail, an ice-pick, or any usually and readily available pointed instrument as if a special opener were used, the latter be-

ing, of course, always preferable when bottles are required to be opened rapidly. My present caps in their best forms have outwardly-flared edges, and the heads of the bottles below their locking-shoulders are of such form and diametrical dimensions that when the cap is locked upon the bottle there is ample space below and at the rear of the flange to admit of the free insertion of any pointed or thin-edged device capable of serving as a bottle-opener by prying the flange outwardly from the locking-rib at several points and thus releasing its hold thereon. The projected edge of the cap so applied also enables the use therewith of special bottle-openers operating as levers, as with my prior caps. When a special bottle-opener is employed, quite heavy detaching force is necessary, because of the practically simultaneous detachment of the cap from the shoulder on the bottle at many points of locking contact; but in operating within the space at the rear of the pendent edge of the flange, as with a knife-blade, for instance, the detachment is gradually effected at each of the points of locking contact, and hence but little manual force is required.

Now with relation to sealing-disks it is to be understood that at the outset I was well aware that cork was the most desirable material; but in view of the high cost of cork and of the presence therein of holes or pits and the apparent necessity that cork disks should be of considerable thickness prompted the devising by me of various substitutes for cork, some of the best of which have been disclosed in my aforesaid prior applications. Some of said disks were essentially quite thick, and hence I first used therewith a flat-topped cap and a bottle having a sharp-edged lip, which was embedded in the disk. With the thinner disks next used with narrow flanged caps such a deep embedding of the lip as was practicable and desirable with the thick disks was rendered objectionable, and hence I used a flat-topped cap and a bottle having a flat-edged lip. With both the thickest and the thinner disks there was a more or less, but far from extensive, packing contact with the annular surfaces inside and outside of the bottle-lip. I have now provided for a specially extensive area of packing contact by using a bottle having a lip well rounded on its outside and a thin disk capable of enveloping and lying in close conformity with the said outer rounded surface. I am thus enabled to secure very satisfactory results with very thin composite compressible disks and caps of a minimum size and weight, because a large proportion of the area of the disk is interposed between coincident surfaces of the cap and the outer rounded surface of the bottle-lip, and said disk is maintained under very high compression. At this stage of my invention I realized that inasmuch as such very thin disks of the composite types (linoleum, felt-paper, with various protecting-coatings, &c.) could be successfully used it would warrant the use of cork, even of the most expensive grades, because said sealing-disks may be normally not thicker than, say, one-sixteenth of an inch. While pursuing this line of experiment I made what may be termed a "paradoxical discovery"—viz., that with the extensive areas of contact and compression now provided by me and with the attendant possibility of using extremely thin disks a perfect gas and liquid sealing effect could be secured and practically maintained for an indefinite time by the use of disks composed of the cheap and ordinary grades of cork, which are well known to contain numerous holes and pits and also streaks of matter quite unlike the main or effective portions of the cork-wood. It is to be understood, however, to accomplish this result that the cork-wood must not only be peculiarly cut, but also subjected to special mechanical treatment. In this connection it will be remembered that in forming ordinary cylindrical or tapered bottle-corks the wood (or bark) is so cut that in each cork the lines of pits or holes are crosswise or at right angles to the axis of the cork, so that when the latter is inserted in the neck of a bottle the contact-surface of the glass closes the entrances to said holes or pits, and therefore their presence does not materially impair the sealing capacity of the cork. Now in cutting my disks from the wood special care is taken to have said lines of perforations or holes or pits parallel with the axis of the disk, and although the disks may be no thicker than one-sixteenth of an inch and be in fact reticulated or perforated they are nevertheless reliable sealing-disks as used by me, because the holes or perforations are so far surrounded by masses of true cork that when the disks are heavily compressed the cork around each hole is rendered impermeable and the ends of each hole are tightly closed, respectively, by the coincident inner surfaces of the rounded topped cap and the outwardly-rounded bottle-lip.

Now as to the necessity for mechanical treatment of the cork disks, I will state that cork-wood (especially the cheaper kind) contains numerous small masses of hard, solid, and almost flinty matter wholly unlike that of the true cork-wood, and it is quite difficult to get a disk which does not contain several of these hard spots. Such hard spots will not become softened by soaking in hot water or steaming, as is usually employed with corks. If such disks be used for sealing, the heavy pressures incident to the application of the caps are insufficient for crushing said hard masses of matter, and their presence would be sometimes indicated by well-developed indentations in the tops of the caps (notwithstanding they are composed of hard sheet metal) with a resultant liability of leakage. For obviating said difficulty I discovered that I must subject the cork disks to a crushing pressure, which so flattens, crushes, or disintegrates said hard masses that they cannot

operate obstructively in the sealing operation. It is to be understood that said disks and the method or process of preparing them will be made the subject of a separate application for Letters Patent. (See Serial No. 417,285, filed January 7, 1892.) It is obvious that in the use of such cork disks the liquid contents of a bottle cannot be excluded by the disks from contact with portions of the cap, and therefore the interior surface of the caps is coated with an inodorous, tasteless, and practically insoluble protecting material.

For more particularly describing my invention I will refer to the accompanying drawings, and after a description thereof the features deemed novel will be specified in the several clauses of claim hereunto annexed.

Referring to the drawings, Figure 1, in side view, illustrates a bottle-head adapted for use in combination with my cap and a sealing-disk. Figs. 2 and 3 respectively illustrate in side view and section a bottle-head with one of my caps and a sealing-disk applied thereto. Fig. 4, in side and top views, illustrates a cap prior to its application to a bottle. Fig. 5, in top and edge views, illustrates a sealing-disk of a composite character in its normal form. Fig. 6, in top and edge views, illustrates a sealing-disk in its normal condition composed of ordinary cork and fairly indicating the open or porous character of such disks as have been successfully used by me with my caps in maintaining gas or air tight closure even under much higher pressures than are ever needed in bottling. Fig. 7 illustrates a cork disk in the form which it is made to assume within the cap and after it has been subjected to heavy pressure for reducing its hard spots. Figs. 8, 9, and 10 respectively illustrate a sheet-metal blank from which the cap is formed, the shape first developed therefrom and the final shape, these being in section with the sealing-disks therein.

Commencing with the bottle-head A, (shown in Fig. 1,) it is to be understood that it differs from such as have been heretofore devised by me in the contour of its lip and of the packing-surface outside of and below said lip above the locking-shoulder, as well as below said shoulder. The lip a is well rounded instead of being quite angular, sharp, or flattened, as in different forms of my prior bottles, and the exterior packing-surface a' below the lip is also well rounded instead of being, as before, quite straight and inclined. The locking-shoulder b is substantially as in some of my prior bottles; but from the recess c below the shoulder downwardly, as at c', the surface of the head is straight or inclined for a short distance instead of being quite abruptly rounded outwardly, as in my prior forms. These differences in form are each of importance in the attainment of some of the specific results now sought by me, as will be hereinafter made apparent.

The metal cap B and its disk C or C′ will first be described in connection with those features which specially relate to their combination with a bottle having a locking-shoulder on its head and constructed, as described, below said shoulder, and it is now to be understood that after a bottle has been filled and the cap, with its disk, has been placed thereon heavy pressure is then applied to the cap and disk, and then the flaring edge of the flange d of the cap is so bent downwardly and inwardly that an annular portion of said flange, as at d', is forced beneath and into reliable engagement with said locking-shoulder; but instead of the lower inside edge of the flange lying closely against the surface of the glass, as heretofore provided for by me, the said edge, by reason of its being now beveled outwardly and also by reason of the shape and dimensions of the bottle-head adjacent to said edge, stands off from the surface of the glass, so as to thereby afford a free annular space at e between the lower portion of the flange and the adjacent surface of the head, and a free entrance to said space is secured for the ready insertion of any sharp or pointed instrument, as indicated in dotted lines in Fig. 3, for service as a bottle-opener by prying the flange of the cap outwardly from the locking-shoulder, as previously described. It will now be seen, although the cap would be well locked and although this bottle-head need be neither unduly large in diameter nor in length, that the flange of the cap may be of a lesser diameter than that of the rounded portion of the head, notwithstanding the liberal annular space e at the rear of the flange. As the result of this peculiar and novel combination of the cap and bottle no special bottle-opener is needed, although the edge d^2 of the cap-flange is so well projected that special bottle-openers may be used, if desired. Any form of sealing-cap applied to and in combination with a bottle-head which is recessed below the locking-shoulder and below and at the rear of the flange and which affords the freely-accessible annular space e will involve this portion of my invention.

Now, more specifically describing the sealing-cap B, as shown in Fig. 4 and as it appears prior to its application to a bottle, it differs from any of my prior caps in that at the junction of the flange and top it is well rounded, as at a^2, so that its corresponding inner surface will correspond with or conform to the rounded packing-surface a' on the bottle-head, this being an essential feature when thin sealing-disks C or C′ are used. As these disks are not or need not normally be more than one-sixteenth of an inch in thickness, and as they are generally reduced to at least one-fourth of that thickness by the requisite sealing compression, it is obvious that the surfaces between which the disk is compressed should be thoroughly coincident, or at least in substantial conformity. With the thick or heavy disks as heretofore used by me and with caps rounded to a minimum

or to any degree at the junction of the flange and top and whether the bottle-lips were flat or sharp, the main point sought was the embedding of the lip in the disk. A comparison of my caps, disks, and bottles and their combination as now disclosed with my prior caps, disks, and bottles and their combination as heretofore devised and disclosed by me, will enable it to be seen that my present improvements involve novel principles of substantial value. With a sharp-lipped bottle and the flat-topped cap a disk as now used by me would be inevitably cut on the line of compression and the sealing effect defeated; but with the outwardly-rounded lip and the extended area of packing contact and the correspondingly-formed cap no cutting action is possible. The thick disks before used and applied by me were essentially impermeable to liquid, and the sealing effect was due, mainly, to the packing contact between the impermeable surface of the disk and the lip of the bottle; but with the thin disks and the rounded coincident surfaces of the bottle-head and the cap permeability of the disk is a matter of no consequence so far as relates to the sealing effect, as will now be made fully apparent.

Referring to Figs. 6 and 7, it is to be understood that the sealing-disk C′ is composed of a thin slice of cork-wood of a low ordinary grade and full of pits or irregularly-shaped holes *f*, which extend completely through the disk, so that when such a disk is held up to the light and close to one's eye it will but little obstruct the vision. In some cases the partitions between the original holes are broken away, forming large ragged holes; but whether the holes are large or small all but those at the extreme edge of the disk are surrounded or bounded by serviceable cork, and hence when the disk is compressed between the surfaces a^2 of the cap and $a\,a'$ of the bottle-lip some of the small holes will be quite closed in or up by the compression of the adjacent cork, and such as are not so closed are tightly walled on one side by glass and on the other side by metal, and the several portions of integrally-communicating cork, although of extremely limited bulk, perform their packing functions more fully than when in larger masses and in the ordinary forms of bottle-corks. It will be seen, however, that, while it is essential in an ordinary bottle-cork that the lines of holes or pits in the cork-wood should be at right angles to the axis of the cork, said holes or lines of holes must be parallel with the axis of a sealing-disk, as before described.

It is obvious that with a thin disk permeable except at its compressed portion it is important that the metal cap should be so coated on its inner side that no metallic taste can be imparted to the liquid contents of a bottle, and for this purpose I apply to the interior of the caps a surfacing of inodorous, tasteless, and insoluble liquid-proof material. It is to be understood that this resistant or non-corrodible coating need only be a very thin film, and I secure the best results by the use of a fusible adhesive material which is tasteless and odorless—such as thin shellac varnish—applied to the interior of the caps and well dried, although a varnish composed of Egyptian asphaltum and aromatic benzole affords quite satisfactory results.

The combination of a metallic sealing-cap coated inside with a protecting film and a permeable or porous sealing-disk is a valuable portion of my invention, and especially if the sealing-disk be composed of cork.

The very hard spots or masses of various sizes and forms found in all ordinary cork will, as hereinbefore indicated, render thin cork disks more or less defective as compressed sealing-disks whenever such hard matter is located in that annular portion of a disk which is compressed between a cap and the packing-surface of a bottle. I therefore, prior to the application of the disks to bottles, free the disks from said hard spots. In other words, I subject them to a heavy pressure, which breaks or crushes and disintegrates the normally hard masses, so that they cannot operate obstructively during the compression of the disk between the bottle and the cap. This crushing operation may be performed prior to the insertion of the disks into the caps; but it is best accomplished at the time the disk is forced into the cap, the latter having had its interior already coated with a film of well-dried shellac, and then heated sufficiently to melt the shellac and render it adhesive, it being always too insufficient in quantity to cause it to flow and to fill the holes or pits in the cork, as will now be described.

Referring to Figs. 4, 6, 7, 8, 9, and 10, it is to be understood that the cap B is developed from a thin tinned iron disk *g*, Fig. 8, which is first struck up and formed into the shape shown in B′, Fig. 9. The flange *d* of this cap B′ is flared to a greater extent than in the finished cap B, as will be seen upon a comparison of Figs. 9 and 10. A cork disk as received from the cork-cutting machine is placed in the cap B′, previously coated inside with shellac and well heated, and then subjected to heavy crushing pressure in suitable dies, and the edge of the flange is compressed, thereby flattening the inner lower portions of the corrugations and slightly reducing the diameter of the flange at and near its edge. Under this operation the hard spots in the cork are not only crushed, but the cork disk is developed into a concavo-convex form, and it is also well confined in the cap by the melted shellac.

The cap B, having the rounded edge at its top, is free from liability of displacement or partial loosening under such edgewise blows on the cap as are incident to handling filled bottles, and said rounding of the top edge also prevents the metal from being lifted at said

edge out of packing contact, even if the center of the cap should be lifted or sprung outwardly under specially powerful gaseous pressure, and therefore it is to be understood that the well-rounded top is an important feature of novelty, but that with respect of its corrugations it is substantially in accordance with my previous disclosures; but in some of my prior caps the edge of the flange was flattened or flared for the sole purpose of causing said edge to lie closely in contact with the surface of a bottle-head rounded outwardly immediately below the locking-shoulder, whereas in my present combination said flattened edge is for an exactly opposite purpose, or, in other words, so as to locate it remotely from the adjacent surface of the bottle-head, which is straight and inclined below the locking-shoulder for a suitable distance, so as to afford the specially useful annular space below and at the rear of the lower portion of the flange. It will also be readily understood that the form and character of the corrugations are immaterial to my present invention, inasmuch as they may be long, short, large, small, straight, or spiralled, because in either case the flanges are to be always bent or crimped into locking contact with the annular shoulder on the bottle-head in such a manner as to afford the annular space *e*, this being wholly independent of the corrugations.

Having thus described my invention, I claim as new and desire to secure by Letters Patent—

1. The combination, with a bottle having a head provided with an annular locking-shoulder adjacent to its lip and a straight or inclined surface below the recess beneath said shoulder, of a metallic sealing-cap containing a sealing-disk and having a flange which is bent or crimped into locking contact with said shoulder above the edge of the flange, the said edge being located remotely from the adjacent surface of the bottle-head to afford between the lower portion of the flange and the adjacent surface of the bottle-head an annular space which is freely accessible to any pointed instrument applied for detaching the cap, substantially as described.

2. The combination, with a bottle having a head provided with an annular locking-shoulder adjacent to its lip and a straight or inclined surface below the recess beneath said shoulder, of a metallic sealing-cap containing a sealing-disk, and having a flaring-edged flange which is bent or crimped into locking contact with said shoulder above its flared edge, the latter being located remotely from the adjacent surface of the bottle-head to afford between the lower portion of the flange and the adjacent surface of the bottle-head an annular space which is freely accessible to any pointed instrument applied for detaching the cap, substantially as described.

3. The combination, with a bottle having on its head and between its lip and neck an annular locking-shoulder and a rounded packing-surface above and extending to the lip from said shoulder, of a metallic cap containing a thin concavo-convex heavily-compressed sealing-disk and having a top which is rounded in conformity with the packing-surface on the bottle-head and has a flange which is bent or crimped into locking contact with said shoulder, substantially as described.

4. A metallic flanged sealing-cap adapted to receive the head of a bottle and containing a concavo-convex sealing-disk and an interposed film of inodorous and tasteless adhesive matter which not only secures reliable initial union of the cap and disk, but also protects the interior surface of the cap against corrosion by liquids permeating the disk, and also prevents metallic tainting of the contents of a bottle sealed by means of said cap and disk, substantially as described.

UNITED STATES PATENT OFFICE.

ROBERT G. CLARK, OF NEW YORK, N. Y., ASSIGNOR TO JOHN ARON JOHNSON, OF BROOKLYN, NEW YORK.

BOTTLE-CAP-ASSEMBLING MACHINE.

1,134,031. Specification of Letters Patent. Patented Mar. 30, 1915.

Application filed August 20, 1913. Serial No. 785,637.

To all whom it may concern:

Be it known that I, ROBERT G. CLARK, a citizen of the United States, and resident of the city of New York, borough of Brooklyn, county of Kings, and State of New York, has invented certain new and useful Improvements in Bottle-Cap-Assembling Machines, of which the following is a specification.

This invention relates to a machine for assembling bottle caps. These caps consist of a metal cup shaped member having a facing of cork in the form of a flat disk secured to the inner surface of the cap.

The object of the invention is to provide a machine for placing these cork facings in position and securing the same in the cap automatically.

In the machine embodying the invention as illustrated in the accompanying drawings a flat rotary table receives the metal caps from a hopper, the caps being fed to the table by a chute. These caps are formed with a flaring edge which is utilized as a means for supporting the caps while the same are being advanced through the successive operations thereupon. The caps are carried forward by the rotary table into position to be engaged by a shifter finger, by means of which the same are moved upon a pair of parallel supporting rails upon which the caps are supported by their flaring edges.

The feeding mechanism comprises a finger bar of peculiar construction to which is imparted a rotary motion enabling it to engage the caps carried by the supporting rails during a portion of its movement and advance the same successively with an intermittent movement along the supporting rails. This feeding mechanism, while peculiarly adapted for use in this machine, may also be adapted for use in other machines and mechanisms for various purposes where a feeding device is useful.

The next step in the operation of assembling is the placing of an adhesive, such as a gummed disk of paper or other suitable material, in the cap for securing the cork disk in position. For this purpose an automatic mechanism is provided which punches the gummed disks from a strip and positions the same in the caps. Means are also provided for preventing the operation of this mechanism except when the caps are being fed thereto by the feeding mechanism. The caps are next advanced along the supporting rails by the feeding mechanism over burners or other heating means which melts or softens the adhesive material to the proper consistency to hold the cork facing. The cork facings, usually in the form of flat disks, are fed by a suitable mechanism which operates automatically to place the same in position in the cap. Means are also provided in connection with this mechanism which automatically prevent the operation thereof if no caps are being fed thereto by the feeding mechanism. After the cork facings have been placed in the caps the feeding mechanism delivers the same to a rotating table upon which are mounted a series of punches or pressure plungers which press the cork facings against the adhesive material in the caps and hold the same together while cooling and finally release and deliver the assembled caps.

The above and other features of the invention will be described more fully hereinafter in connection with the description of the machine shown in the accompanying drawings as illustrative of one operative embodyment of the same.

In the drawings like parts in the several views have been given the same reference numerals.

Figure 1 is a plan view of one end of the machine. Fig. 2 is a plan view of the opposite end of the same. (Figs. 1 and 2 form one complete plan view of the machine.) Fig. 3 is an enlarged sectional view on the line 3—3 of Figs. 1 and 4. Fig. 4 is an enlarged side elevation, partly in section, on the line 4—4 of Figs. 1 and 3. Fig. 5 is an enlarged sectional view on the line 5—5 of Figs. 2 and 8. Fig. 6 is a side elevation of Fig. 5. Fig. 7 is a sectional view on the line 7—7 of Figs. 2 and 8. Fig. 8 is a plan view of Figs. 5, 6 and 7, partly broken away. Fig. 9 is a detail sectional view on the line 9—9 of Fig. 8. Fig. 10 is a perspective view of the right hand end of Fig. 1. Fig. 11 is a perspective view of a portion of Fig. 3. Fig. 12 is a perspective view of a portion of Figs. 2 and 8.

A flat rotary table 1 is rotated in the direction indicated by the arrow in Figs. 1 and 10 by the vertical shaft 2 driven by the bevel gears 3 and 4 from the main driving shaft 5. This shaft is driven by means

of suitable pulleys, such as 6, shown in Fig. 2. The caps are fed to the table 1 from a chute, not shown, the caps being indicated by the dotted circles in Fig. 1 and are carried between the horizontal guides 7 and 8 by the movement of the table 1.

The shifter finger 9 is pivoted at 10 and is oscillated by a link 11 acting in conjunction with a spring 12 and successively engages the caps, pushing the same to the left into position to be engaged by the finger bar 13.

The finger bar 13 consists of a long flat bar slidably mounted and provided with a series of projections on one side spaced to receive the caps, allowing a slight clearance. This finger bar 13 is mounted upon a support 14, shown more clearly in Figs. 7 and 8, which is provided with two extensions 15 and 15′ connected to the crank members 16 and 16′ mounted upon the vertical shafts 17 and 17′, respectively. These shafts are driven by bevel gears from the main shaft 5, as shown. It will thus be seen that a rotary reciprocating movement is imparted to the finger bar 13 which causes the projections thereon to successively engage and advance the caps with an intermittent movement, the throw of the crank members 16 and 16′ being substantially equal to the diameter of the cap. As the caps are thus advanced the same are received upon and suspended from a pair of parallel supporting rails 18 and 19, which have their upper inner edges beveled to carry the caps suspended from their flaring edges so that the finger bar engages the body of the cap.

The mechanism for placing the adhesive material in the caps is shown in Figs. 3, 4 and partly in Fig. 11. An eccentric 20 is operated from the shaft 5. The eccentric arm 21 is connected to oscillate a lever 22, which is pivotally mounted at 23. The upper end of the lever 22 operates a slide 24 which is slidably mounted in the cross support 25 by the T shaped member 26. The slide 24 is provided with a projection extending upwardly and over the cross support 25 carrying a weighted pawl 27. A similar pawl 28 is pivotally mounted upon the frame of the machine. The pawl 27 carries a flexible member 29, preferably of rubber, at its lower end and the pawl 28 carries an engaging member 30 similarly located. A strip of gummed paper is fed from a roll, not shown, between the guides 31 and 32 over the cross support 25 and under the portions 29 and 30 of the pawls 27 and 28. The slide 24, carrying the pawl 27 is oscillated and moves the strip of gummed paper along the cross support 25, the strip being held against the return movement by the pawl 28 and its engaging portion 30. It will be seen that a wedging action is produced on the forward movement between the flexible member 29 on the pawl 27 and the paper strip, holding the paper against the member 26 of the slide 24 and a like action is produced by the pawl 28 against the paper upon the return movement, thus causing the paper strip to be advanced by the forward movement and held against the return movement.

A punch 33 is mounted in a vertically sliding carrier 34 and operated by the eccentric 35 on the shaft 5 through the eccentric arm 36. The punch is positioned over the cross support 25 and the strip of gummed paper, from which disks are punched and dropped into the caps as the same are advanced successively thereunder, carried by the supporting rails 18 and 19. In the recess in the bottom of the punch 33 is positioned a small disk 37 mounted upon a stem 38, which extends through a longitudinal opening in the punch and is provided with an adjustable stop at its upper end. The purpose of this is to cause the disk of gummed paper when cut from the strip to fall into the cap beneath, which might otherwise stick to the punch, the weight of the disk 37 and stem 38 being sufficient to push the disk out.

In case no caps are being fed by the finger bar 13 it is desirable to prevent the paper feeding mechanism from operating and for this purpose a weighted lever 39 is pivoted to the frame at 40. This lever is provided at one end with a weight 41 carrying a contact piece 42, which is positioned over the path of the caps and holds the lever 39 up, or in its inoperative position while any caps pass under the same. (See Figs. 1 and 11.) When there are no caps being fed the weighted end of the lever 39 falls and the opposite end is raised and engages a pivoted latch 43, (see Figs. 4 and 11,) swinging the upper end of the same inwardly into the path of a pin 44 on the pawl 27, holding the same out of engagement with the gummed strip of paper and preventing the feeding until released by the raising of the inner end of the lever 39 by the caps again passing under the same. It will thus be seen that the operation of this mechanism is controlled automatically by the presence or absence of the caps which are to receive the adhesive material supplied thereby.

After the adhesive material is placed in the caps, as just described, the same are advanced along the supporting rails 18 and 19 by the finger bar 13 over the flames from a number of gas jets supplied from a perforated pipe 45, shown in Fig. 3, or other suitable heating means. This melts or softens the adhesive material preparatory to receiving the cork facings. During this portion of their travel the caps are held against displacement on the supporting rails 18 and 19 by means of a bar 46, shown in Fig. 1, which

is positioned over the path of the caps and rests lightly thereon and is hinged at one side, as at 47 and 48, to the frame and provided with a weighted handle 49 extending on the opposite side. This construction permits the bar 46 to be raised to provide access to the caps for removing any that may become displaced, etc.

The mechanism for placing the cork facings in the caps is shown in Figs. 5 to 8 inclusive. These facings are in the form of disks of cork cut to size and placed in a vertical tube 50. An eccentric 51 on the shaft 5 is connected by the pitman rod 52 to a pivoted lever 53, which, in turn, is operatively connected to and oscillates a slide 54. On the forward movement a shoulder on the slide 54 engages a cork shifter slide 56, which is provided with a semi-circular recess at one end for engaging the lowermost of the cork disks in the tube 50 and moving the same forward beneath the plunger 57 over one of the caps advanced by the finger bar 13 upon the rails 18—19. On the return movement of the slide 54 the rear end engages a latch 55, which is pivotally attached to the cork shifter slide 56.

The plunger 57 is carried in a sliding head 58 mounted on the frame and operated by an eccentric arm 59 from the eccentric 51. The plunger 57 carries a sleeve 60 which has a tapered lower end and is slidably mounted upon the plunger and supported by a spring 61. The purpose of this sleeve is to locate or center the cap beneath the plunger so that the cork facing will be properly placed or positioned therein. Means are provided for preventing the operation of this mechanism and stopping the feeding of the cork facings when there are no caps being fed beneath the plunger. These means are shown in Figs. 7 and 8 and consist of a lever 62 pivotally mounted upon the frame of the machine at 63 and provided at one end with a foot piece 64 which rests upon the caps as the same are advanced thereunder. The lever 62 is thus normally held in inoperative position and permits the cork feeding mechanism to operate as just described. Should no caps be present, however, the inner end 64 of the lever 62 being unsupported allows the outer end to be raised by the action of the spring 65 and its plunger 65′ positioned beneath the outer end of the lever 62. A projection 55′ from the latch 55 passes between the end of the lever 62 and the plunger 65′ and the latch 55 is thereby raised out of engagement with the slide 54, consequently, the cork shifter slide 56 is not returned with the return movement of the slide 54 and the feeding of the corks is thus automatically prevented as long as no caps are being advanced by the finger bar.

The caps are now delivered to a rotating table 66, which is revolved by the vertical shaft 67 driven by a worm and gear from the main shaft 5, as shown in Fig. 2. Upon the table 66 a number of pressure plungers 68 are mounted, these being indicated in Figs. 2 and 8 and shown in detail in Fig. 9. The plungers 68 are slidably mounted in a bracket 69 attached to the table 66. A spring 70 normally holds the plunger 68 against the cork facing in the cap and presses the same together while cooling, this taking place during one revolution of the table 66.

The end of the supporting rail 19 is bent to extend angularly over the revolving table 66 and a flat cap 71 is secured on top of this angular portion extending over the beveled edge for holding the flaring edge of the caps as the same are fed upon the table by the movement of the finger bar 13. (See Figs. 8 and 12.) A swinging finger 72 is pivotally mounted upon the rail 19 and extends over the table 66. The end of this finger 72 is swung out of the path of the caps successively by engagement with the plungers 68 and as the plunger ahead of the one about to receive the cap passes out of engagement with the finger the finger 72 the same snaps back, by the action of the spring 75, against the cap, which has just been advanced upon the table 66 by the finger bar 13, and positions the cap against the shoulder 66′ on the table 66 and the rail 19, with its flaring edge under the cap 71, and holds the cap until the following plunger 68, which passes off from the cam 73, engages the same. The cam 73 is stationary and positioned in the path of the plungers 68, the outer end being inclined engages in a slot in the plungers 68, as shown in Figs. 2 and 9, and raises the same successively from the caps, which are thus released and removed from the table by the further movement of the same under the ejector finger 74, which is mounted on the frame of the machine and extends over the table 66 in the path of the caps when released by the plunger 68, as just described.

As many changes could be made in the above construction and many apparently widely different embodiments of my invention designed without departing from the scope thereof I intend that all the matter contained in the above description or shown in the accompanying drawings shall be interpreted as illustrative merely of an operative embodiment of my invention and not in a limiting sense.

What I claim is:—

1. In a machine for assembling bottle caps and the like, in combination, means for receiving the caps, a pair of parallel supporting rails upon which the caps are suspended from their flaring edges, means for shifting

the caps successively to the supporting means, a hinged bar positioned over the path of the caps upon said rails and resting lightly thereupon to prevent their displacement, means for advancing the caps successively upon said supporting rails during the operation of assembling, means for placing an adhesive in said caps, means adapted to automatically control the operation of said adhesive placing means, means for heating the cap and adhesive therein, means for placing cork facings in said caps, means adapted to automatically control the operation of said cork placing means, means for pressing the cork facings and caps together against the adhesive, and means for delivering the assembled caps from the machine.

2. In a machine for assembling bottle caps and the like, in combination, means for receiving the caps, means for shifting the caps successively to a supporting means upon which the caps are supported and guided in a straight path, means for advancing the caps successively upon said supporting means during the operation of assembling, a pawl carried by an oscillating slide adapted to feed a strip of adhesive paper to a punch, a punch positioned over the path of the caps adapted to punch disks from the strip of adhesive paper and place the same successively in the caps, a lever having one end weighted and positioned over the path of the caps and held thereby in its inoperative position and having its opposite end arranged and adapted to hold said feeding pawl in an inoperative position when no caps are being fed, means for heating the cap and adhesive therein, means for placing cork facings in said caps, means for pressing the cork facings and caps together against the adhesive, and means for delivering the assembled caps from the machine.

3. In a machine for assembling bottle caps and the like, in combination, means for receiving the caps, means for shifting the caps successively to a supporting means upon which the caps are supported and guided in a straight path, means for advancing the caps successively upon said supporting means during the operation of assembling, means for placing an adhesive in said caps, means for heating the cap and adhesive therein, a cork shifter slide for feeding the cork facings to the caps, a latch pivotally attached to said cork shifter slide and normally engaging an oscillating slide, a lever having one end positioned over the path of the caps and held thereby in its inoperative position and having its opposite end arranged and adapted to automatically control the position of said latch and the movement of said cork shifter slide, means for pressing the cork facings and caps together against the adhesive, and means for delivering the assembled caps from the machine.

4. In a machine for assembling bottle caps and the like, in combination, means for receiving the caps, means for shifting the caps successively to a supporting means upon which the caps are supported and guided in a straight path, means for advancing the caps successively upon said supporting means during the operation of assembling, means for placing an adhesive in said caps, means for heating the cap and adhesive therein, means for placing cork facings in said caps, a revolving table upon which the caps are received, a series of pressure plungers mounted on said table adapted to press the cork facings and caps together against the adhesive, means actuated successively by said plunger for positioning and holding the cap in position to be engaged by the following plunger, and means for delivering the assembled caps from the machine.

5. In a machine for assembling bottle caps and the like, in combination, means for receiving the caps, means for shifting the caps successively to a supporting means upon which the caps are supported and guided in a straight path, means for advancing the caps successively upon said supporting means during the operation of assembling, means for placing an adhesive in said caps, means for heating the cap and adhesive therein, means for placing cork facings in said caps, a revolving table upon which the caps are received, a series of pressure plungers mounted on said table adapted to press the cork facings and caps together against the adhesive, a spring actuated finger extending over said table in the path of the caps and successively engaged by said plungers to move the same out of the path while each cap is being fed to the table and adapted when released to position and hold the cap in position to be engaged by the following plunger, and means for delivering the assembled caps from the machine.

6. In combination, means for feeding the caps, means for placing an adhesive in said caps, means for placing cork facings in said caps, a revolving table upon which the caps are received, a series of pressure plungers mounted on said table adapted to press the cork facings and caps together against the adhesive, a finger extending over the table into the path of the caps and successively engaged by said plunger to move the same out of the path while each cap is being fed to the table, and adapted when released to position and hold the cap in position to be engaged by the following plunger and means for delivering the assembled caps from the machine.

7. In a machine for assembling bottle caps and the like, in combination, means for receiving the caps, a pair of parallel supporting rails upon which the caps are suspended from their flaring edges, means for shifting

the caps successively to the supporting means, a hinged bar positioned over the path of the caps upon said rails and resting lightly thereupon to prevent their displacement, and means for advancing the caps successively upon said supporting rails during the operation of assembling.

8. In a machine for assembling bottle caps and the like, in combination, a rotary table, means for feeding the caps to said table, a pair of guides extending over said table, a pair of supporting rails upon which the caps are adapted to be received from said table, a reciprocating finger bar arranged under said supporting rails, and adapted to shift said caps successively along said rail, an oscillating shifter finger extending over said table and adapted to successively engage the caps and shift them to the supporting means, said shifter finger being actuated by the motion of said finger bar.

9. In a machine for assembling bottle caps and the like, in combination, means for successively feeding the caps means for placing an adhesive in said caps, means for heating the caps and adhesive therein, means for placing cork facings in said caps, a revolving table upon which said caps are received, a series of plungers mounted upon said table adapted to press the facings and caps together upon the adhesive, means successively operated by said plungers for positioning and holding the caps for engagement by the following plunger and means for delivering the finished cap from the machine.

10. In a bottle cap assembling machine, and the like, in combination, means for feeding the caps, means for placing an adhesive in said caps, means for heating the cap and adhesive, means for placing a cork facing in said caps, a rotary table upon which the caps are received, a series of pressure plungers on said table, an annular shoulder formed on said table, a stationary member extending over said table, a spring actuated finger extending over the said table in the path of the caps, and successively engaged by said plungers to move the same out of the path while each cap is fed to the table and adapted when released to force said cap against said annular shoulder and said stationary member for engagement by the following plunger and means for delivering the assembling caps from the machine.

11. In a machine for assembling bottle caps and the like, in combination, a supporting means, means for advancing the caps intermittently upon said supporting means during the operation of assembling, means for intermittently feeding a strip of adhesive paper over the caps during the period of advancement of said caps, a punch positioned over the path of the caps adapted to punch disks therefrom and place the same successively in the caps during the period of rest, and means controlled automatically by the caps to control the operation of said strip feeding means.

12. In a machine for assembling bottle caps and the like, in combination, means for delivering the caps, a rotary table upon which the caps are received, a pair of parallel supporting rails, a reciprocating finger bar adapted to engage and advance the caps successively during the operation of assembling, means for successively shifting said caps to said supporting rails comprising a pair of horizontal guides extending from said table and between which the caps are carried by the rotation of said table and an oscillating shifter finger operated by the reciprocation of said finger bar adapted to successively engage the caps and place the same in position to be engaged by the finger bar.

13. In a machine for the manufacture of bottle closures of the cap variety, the combination with transporting means for a metallic cap, of means for cutting a disk from a strip of binding material and inserting it into the cap, means for feeding the strip to said cutting means, and means for rendering said feeding means inoperative if said transporting means fails to bring a cap into registering position with said inserting means.

Signed at the city of New York, in the county and State of New York, this 18th day of Aug., 1913.

ROBERT G. CLARK.

[fol. 1813] DEFENDANT'S EXHIBIT VVV

(Letterhead of)

Goetz Company, St. Joseph, Mo.,

August 22, 1928.

Ferdinand Gutmann Co., Bush Terminal #19, 39th St. & 2nd Ave., Brooklyn, N. Y.

GENTLEMEN:

We have to-day made further test with the aluminum center crowns you sent us. We took 500 crowns which had gone through our shaker, wherein the spots seemed securely fastened and put them in an Adriance Crowner and run the machine for ten minutes without crowning any bottles, in order to ascertain what effect the agitation in hopper would have on discs.

After removing same from machine we found three dozen crowns that the discs came off entirely and fully fifty percent of the rest were loose and hanging at one point only.

You are no doubt already aware that the discs falling off of crowns would choke up crowner chute and stop the operation of the crowner.

Yours very truly, M. K. Goetz Brewing Co., (Signed) A. N. Ketterer, Supt. Btl. Dept.

ANK/ELA.

[fol. 1814] (Letterhead of)

M. K. Goetz Brewing Co., St. Joseph, Mo.

August 23, 1928.

Ferdinand Gutmann & Co., Bush Terminal No. 19, 39th St. & 2nd Ave., Brooklyn, N. Y.

GENTLEMEN:

On my return I found your letter of August 13th and also that it has been taken care of and that you received the required information as to our requirements, also that you should ship on September 1st a car consisting of one half regular cork disc crowns and one half of aluminum centered crowns. This was quite correct before we received and tried

out the case of aluminum centered caps which you sent as a trial lot. It is extremely fortunate that this sample lot was shipped now before you proceeded further with the making of more caps like that.

Mr. Ketterer wrote you at once on the 21st and again on the 22nd and in these letters informed you very thoroughly and correctly as to the results we had with these aluminum centered crowns.

In order to call your attention to the defects at once the following nightletters were sent to you on Tuesday and Wednesday evenings:

August 21st "Aluminum center crowns not usable because many aluminum discs fall out in crown shaker are sending you some of them letter follows"!

[fol. 1815] August 22nd "In using crowns which retained aluminum discs during shaker process more discs were loosened in adriance crowner your system of fastening aluminum to cork entirely wrong (stop) furthermore the aluminum itself is much too heavy almost three times as heavy as aluminum used by others Gutmann promised thinner quality"

These wires and letters have no doubt explained to you that these caps (as you are now making them) are absolutely unsatisfactory and the writer sincerely trusts that you at once stopped their further production.

Referring to the 2nd part of the last wire we find the thickness of the aluminum you used entirely too great. So far as we could we calibered it and find it to be about 0.0085", while the aluminum discs Mr. F. Gutmann submitted in his several trial lots calibers ca. 0.0035" only. We even objected to this and in one of Mr. Gutmann's letters to the M. K. Goetz Brewing Co. or to the writer you will find that he agreed that a thinner aluminum must be used. Instead of that the thickness of the aluminum in your trial lot is between 2 and 3 times greater.

Other manufacturers use aluminum of ca. 0.003" thickness and Mr. E. A. Siebel suggested that even this should be and was in fact being reduced somewhat more.

At any rate your aluminum is entirely too heavy and will result in a great many of the discs being cut thru by the edges of the bottles during the crowning process.

The writer incloses 3 Aluminum discs, one of the smaller ones with several holes punched into it is one of the ones you [fol. 1816] sent now, the other small one from a Bamberger Kraus crown. The large one is from one of the crowns submitted by your Mr. Gutmann, in one of the several test lots of several months ago.

By closely examining these discs you will find that the thickness of your last lot is entirely too great.

The result with this sample lot leaves the matter as it was several months ago and we are very much disappointed indeed and await your explanation and further advices in the premises at the earliest possible date.

In your letter of the 14th in reply to the writer's letter of the 11th you show deep concern in the manner your regular plain cork disc crowns affect the "taste of our products". The writer—during his recent trip—had several occasions to further prove the seriousness of the situation caused by the "plain cork discs".

We were in hopes that the "aluminum centered caps" would change this condition and are still of the opinion that they will do this, but the new condition—created by the unsatisfactory results with your trial lot—is much more than disappointing.

We sincerely trust that you will be enabled to at once remedy the several defects and shortcomings of your aluminum centered crowns and expect to hear from you at once. As we cannot safely use the "regular cork discs" either,—we may be compelled to soon decide on some other means to improve the condition.

Yours very truly, M. K. Goetz Brewing Co., per F. W. Boldenweck, Supt.

FWB/HLC.

[fol. 1817] P. S.—In reference to the Bamberger & Krause, also to the aluminum centered crowns finished by the C. C. & Seal Co. will say that the discs did not loosen during the crown "shaker" period nor during the time the crowns were in the hopper of the Adriance crowner.

In fact none of the discs became loose or came off.

(Letterhead of)

E. I. du Pont de Nemours & Company, incorporated, Parlin, New Jersey, U. S. A.

May 12, 1932.

Ferdinand Gutmann & Co., Bush Terminal No. 19, 39th St. and 2nd Ave., Brooklyn, N. Y.

Attention of Mr. J. B. Eisen

GENTLEMEN:

This will acknowledge the receipt of your letter of May 6th requesting that we send you a sample of our #4620 Thermoplastic Cement, and in accordance with your request we are sending you by prepaid parcel post, without charge, a 1-½ pint can of this material for trial.

[fol. 1818] This cement may be applied by brushing, dipping, spraying or roller coating. It will be found light in color and deposits a clear, nearly colorless film. After applying the cement to the objects which are to be joined, the film should be allowed to dry from 3 to 20 minutes at room temperature, depending on the material coated, and when the solvents have completely evaporated, the objects should be brought together and heated with a hot press, roll, or flat-iron. An ordinary electric flat-iron will suffice and a temperature of between 130 to 150° C. may be employed with a little pressure. The exact heating time, of course, depends on the conductivity of the material through which the heat must pass to fuse the cement.

In cementing most materials where the cement would be applicable, the heat need be applied only momentarily, and on cooling it will set up quickly and will develop a strong bond between the cemented objects. Materials coated with 4620 Thermoplastic Cement may be stored indefinitely without destroying the adhesive properties of the Cement which is only very slightly tacky and the tackiness will not increase unless it is subjected to temperatures above 50° C. (122° F.). It is a waterproof product and can be used advantageously wherever a non-aqueous cement is required, and will be found to have excellent flexibility and adhesion to a wide range of articles.

Our 4620 Thermoplastic Cement is priced at $1.80 per gallon in 50 gallon returnable drums, and is also available in 5 gallon cans at $2.00 per gallon, f. o. b. delivered in Brooklyn.

We hope that your tests with the 4620 Thermoplastic Cement will prove satisfactory and that as a result of them, [fol. 1819] we will be permitted to supply you with this item regularly. As soon as you have had an opportunity to fully demonstrate it, we would appreciate receiving a report from you and if there is any further assistance needed, kindly do not hesitate to call upon us for it.

Yours very truly, J. W. Cleaveland, Eastern Manager Industrial Sales, by H. F. Hall.

[fol. 1839] DEFENDANT'S EXHIBIT LLLL

(Letterhead of)

Schwarz Laboratories, Inc.,

Brewery Consultants and Engineers, 202 East 44th Street, New York

July 24, 1933.

Ferdinand Gutmann & Co., Bush Terminal, Brooklyn, New York.

Attention Mr. Jesse Gutmann

GENTLEMEN:

With reference to the enclosed report, it is definitely our opinion that there is no difference between the two crowns submitted to us for examination. This statement, of course, does not apply to the methods of manufacture involved in the making of these two crowns; it is quite possible that there may be differences of which we know nothing. Our statement that there is no difference between the two crowns is based on the result obtained in the practical test noted on the report.

On completion of the test these samples were examined and tasted by three individual chemists and brewing technologists, who had no knowledge of the question involved. It was their definite opinion in each instance that there was no difference in the appearance of the two crowns involved, nor was there any difference in the taste, odor, or appearance of the beer.

[fol. 1840] We sincerely hope that these tests give you the desired information, but if you have any further inquiries please be assured that these will receive our prompt attention.

Always at your service,

Schwarz Laboratories, Inc., (Signed) Herbert A. Schwarz.

[fol. 1843] DEFENDANT'S EXHIBIT OOOO

Defendant's Interrogatories to Plaintiff and Plaintiff's Answers Thereto

Q. 1. What Claims of each of the patents in suit does plaintiff allege defendant has infringed?

Ans. See Plaintiff's Bill of Particulars.

Q. 2. When was the amalgamation of Crown Cork & Seal of Baltimore City with New Process Cork Co., Inc. effected?

Ans. The Crown Cork and Seal Company of Baltimore City did not amalgamate with New Process Cork Co., Inc. The legal steps were as follows: A New York corporation known as the N. Y. Improved Patents Corporation purchased the assets of The Crown Cork and Seal Company of Baltimore City; thereafter the New Process Cork Co., Inc., and N. Y. Improved Patents Corporation consolidated, forming Crown Cork & Seal Company, Inc., Certificate of Consolidation was filed December 19th, 1927 with the Secretary of State at Albany, New York.

Q. 3. When was the present plaintiff incorporated?

Ans. December 19, 1927.

Q. 4. Were any officers of the plaintiff corporation officers of plaintiff's predecessor, Crown Cork & Seal Company of Baltimore City?

Ans. Yes.

Q. 5. If the answer is yes, give their names?

Ans. F. Erwin Fusting, Edward J. Costa.

Q. 6. Is Wm. Vinson an officer of the plaintiff company?

Ans. Yes.

Q. 7. If so, what office does he hold and what are his duties?

Ans. Vice-President, connected with sales.

Q. 8. Upon what date or dates were the licenses mentioned in the Bill of Complaint and Reply made?

Ans. Attached hereto is a list of the licensees with the [fol. 1844] dates of the license agreements.

Q. 9. Have the terms of the License Agreements since been changed or modified?

Ans. Yes.

Q. 10. In what respects and when?

Ans. The licenses of all licensees, except Truslow & Fulle, were modified by supplemental agreement, copy of which is attached. Further under date of December 19, 1934, Plain-

tiff voluntarily reduced temporarily the royalty terms as shown by letter, copy of which is attached.

Q. 11. Who are the licensees referred to in the Bill of Complaint and the Reply?

Ans. See attached list.

Q. 12. Are any of the licensees, named in answer to Int. 11, the subsidiaries of the plaintiff corporation?

Ans. Yes.

Q. 13. If the answer to Int. 12 is "Yes," give the names of such licensees.

Ans. Western Stopper Co., Inc.

Q. 14. If the answer to Int. 12 is "No," does the plaintiff corporation have any financial interest in the business of any of said licensees.

Ans. No.

Q. 15. If the answer to Int. 14 is "Yes," give the names of such licensees.

Ans. None.

Q. 16. Did the plaintiff corporation authorize the publication of the advertisements in magazines and trade papers as follows:

Western Brewer	p.	Aug. 1934 issue
Brewer & Malster	p.	July 1934 issue
Brewer & Malster	p.	Aug. 1934 issue
Brewer's Journal (Western Brewer)	p.	July 1934 issue
Modern Brewer	p.	Aug. 1934 issue
The Crown	p.	—— —— issue
The Crown	p.	—— —— issue
The Crown	p.	—— —— issue

[fol. 1845] and in what, if any other trade journals or publications advertisements like those above referred to were authorized?

Ans. The following advertisements were authorized:

Western Brewer	Aug.	1934 issue Page 19
Brewer & Malster	July	1934 issue Page 116
Brewer & Malster	Aug.	1934 issue Page 114
Brewers' Journal (Western Brewer)	July	1934 issue Page 13
Modern Brewery	Aug.	1934 issue Inside of back cover.

Substantially corresponding advertisements were also authorized in the following publications in the issues mentioned herein:

American Brewer	July and Aug. 1934 issues
Beverage News	ditto
National Bottlers Gazette	"
National Carbonator and Bottler	"
Western Brewery World	"

Any advertisements appearing in the "Crown of Baltimore," which is the Plaintiff's own publication, under Plaintiff's name, were authorized by Plaintiff.

Q. 18. Did the plaintiff corporation cause to be printed and published a pamphlet entitled "Spot Crowns"?

Ans. Yes.

Q. 19. If the answer to Int. 18 is "Yes," when were such pamphlets first distributed to users of crown caps, how many of such pamphlets have been so distributed and to whom generally?

[fol. 1846] Ans. The booklet entitled "Spot Crowns" was first distributed on or about September 21, 1934; it has been distributed to all those companies whose products are represented in the booklet, and, additionally, to representative or principal users of spot crowns. Approximately 2,000 copies have been distributed.

Q. 20. When did plaintiff or its predecessor, Crown Cork & Seal Company of Baltimore City, first make and sell center spot crowns having a facing disk formed of varnished Express, Kraft or other hard paper having a water finish or of a metal foil secured to the cushion disk of the crown by means of gutta percha or any other water insoluble adhesive material extending throughout the entire surface of the center spot?

Ans. About 1917.

Q. 21. Was a strip of center spot material used on the dates given in answer to Int. 20 in which one surface thereof had bonded thereto a coating of gutta percha?

Ans. No.

Q. 22. Did the plaintiff corporation, or its predecessor Crown Cork & Seal Company of Baltimore City, on or

about May 7th, 1927, or prior thereto, make and deliver for use bottle caps or crowns as described in Int. 20?

Ans. Yes.

Q. 23. If the answer to Int. 22 is "Yes," when and to whom and in what quantities were such crowns or caps delivered?

Ans. Metal foil center spot crowns were made and sold prior to May 7, 1927 detailed sales reports are not available. Paper center spot crowns were not sold prior to May 7, 1927 on which date the first shipment was made to Burroughs Bros., Baltimore, Maryland, totaling ten (10) gross.

Q. 24. Were the caps delivered to the parties above named in answer to Int. 23 charged for?

Ans. Yes.

[fol. 1847] Q. 25. Did the plaintiff corporation, or its predecessor Crown Cork & Seal Co. of Baltimore City, ever use varnished Express or varnished Kraft paper in bottle closures of any kind prior to 1925?

Ans. Yes.

Q. 26. If the answer to Int. 25 is "Yes," state who furnished such paper?

Ans. Irvington Varnish & Insulator Co., Pittsburgh Insulator Co.

Q. 27. When did the plaintiff corporation, or its predecessor Crown Cork & Seal Co. of Baltimore City, first manufacture crown Bottle caps having a center spot of varnished paper or of a metal foil, which center spot was adhered to the cushion disk by gutta percha, and in which a strip of gutta percha and a strip of facing material were simultaneously fed in a machine for applying the center spot to the cushion disk?

Ans. In 1917 or 1918; no definite date is ascertainable.

Q. 28. Did the plaintiff corporation, or its predecessor Crown Cork & Seal Co. of Baltimore City, ever manufacture and sell center spot caps in which the center spot disk is secured to the cushion disk by means of a cellulose derivative, cement or adhesive?

Ans. Yes.

Q. 29. If the answer to Int. 28 is "Yes," when were such caps first made and sold?

Ans. June, 1934.

Q. 30. If the answer to Int. 28 is "Yes," in what quantities have such caps been sold to users thereof?

Ans. Large quantities.

Q. 31. When did the plaintiff corporation, or its predecessor Crown Cork & Seal Co. of Baltimore City, first manufacture and sell a center spot crown with a metal foil facing disk secured to the cushion disk by means of gutta percha?

Ans. About 1917.

[fol. 1848] Q. 32. Over what period of time did the plaintiff corporation, or its predecessor Crown Cork & Seal Co. of Baltimore City, continue to manufacture and sell such center spot crowns as are referred to in Int. 31?

Ans. From about 1917 to date.

Q. 33. Does any application for Letters Patent of the United States, other than those referred to in the patents in suit filed by the plaintiff corporation, or its predecessor Crown Cork & Seal Co. of Baltimore City, or by any employee of said plaintiff or said predecessor, and assigned to the plaintiff or its predecessor, refer to the use of gutta percha for securing center spots of any material, whether varnished paper or a metal foil, to the cushion disk in crown caps?

(Answer refused.)

Q. 34. Does an application by Albin H. Warth executed August 10th, 1926, and assigned to the plaintiff or to plaintiff's predecessor, Crown Cork & Seal Co. of Baltimore City, refer to the use of gutta percha for securing center spots of any material, whether paper or a metal foil, to the cushion disk in crown caps, and will plaintiff authorize the defendant to have access to said application?

Ans. Yes, and is identified as Serial No. 130,631, filed Aug. 21, 1926; Defendant may have access thereto.

Q. 35. Are any records of plaintiff's predecessor, Crown Cork & Seal Co. of Baltimore City, relating to center spot crowns, available to the plaintiff corporation, and what period of time do such records cover?

Ans. Incomplete records from 1917 to date are available.

Q. 36. For how long has Albin H. Warth been employed by the plaintiff corporation and its predecessor, Crown [fol. 1849] Cork & Seal Co. of Baltimore City, and what have been his duties?

Ans. Employed on May 17, 1916; he has been Chemical Director since that date.

Q. 37. When did the plaintiff corporation, or its predecessor Crown Cork & Seal Co. of Baltimore City, first deliver center spot crown caps in which gutta percha was used to affix the facing disk to the cushion disk of a cap?

Ans. About 1917.

Q. 38. To whom were such crown caps delivered?

Ans. No information available.

Q. 39. Has plaintiff corporation, since August 8th, 1933, made center spot caps in the following manner:

Depositing a heat fusible cement in a metal shell.

Subjecting said shell and cement to heat.

Depositing a cushion disk within said shell upon said adhesive.

Subjecting the exposed surface of the cushion disk to heat.

Cutting a facing disk from a strip of material having heat fusible, cementitious material applied to the face thereof presented toward the cushion disk.

Applying pressure to said facing disk, said cushion disk and said shell without the presence of heat and until the adhesive has set.

Ans. No.

Q. 40. Has there been any adjudication of any one of the six patents in suit?

Ans. No.

Q. 41. If the answer to Int. 40 is "Yes," state the names of the parties and the Court in which such adjudication was held?

[fol. 1850] Q. 42. Did the plaintiff corporation or anybody for and on behalf of, or for the benefit of the plaintiff corporation, acquire any interest in the Johnson patent prior to December 20th, 1933?

Ans. Yes.

[fol. 1850a] Copy of Letter Modifying Agreement Forwarded to all Licensees on December 19, 1934, and Furnished in Response to Defendant's Interrogatory 10

December 19th, 1934.

GENTLEMEN:

Referring to the Crown Seal Agreement dated the — day of ——, 193-, and the Supplemental Agreement dated the 28th day of September, 1934, this is to advise that until further notice to you and beginning January 2nd, 1935, we hereby voluntarily agree to accept as complete payment for the royalties specified by Paragraph 3 of the Supplemental Agreement, a royalty at the rate of one-quarter of a cent (¼ of 1¢) per gross.

In making this offer, we specifically reserve the right to restore on ten (10) days written notice to you the existing royalty rates as specified in said Paragraph (3) or any rates not exceeding the same.

If this offer, subject to the reservation specified, is acceptable to you, will you please so indicate by your signature at the bottom of this letter and return the same to us, retaining the signed carbon copy herewith.

Yours very truly, Crown Cork & Seal Company, Inc., Licensor, by (Signed) F. E. Fusting, Vice-President.

Accepted: December —, 1934. —— ——, Licensee, by —— ——.

[fol. 1851] Copy of Supplemental Crown Seal Agreement Furnished in Response to Defendant's Interrogatory 10

Crown Seal Agreement

(Supplemental)

Supplemental Agreement

This Agreement, made at New York, New York, this — day of September, 1934, between Crown Cork & Seal Company, Inc., a New York corporation, hereinafter termed "Licensor," and —— ——, a —— corporation, hereinafter termed "Licensee"

Witnesseth: That

Whereas, the parties hereto have heretofore entered into a license agreement relating to the manufacture and sale of crown seals dated the — day of ——, 1933, and

Whereas, the parties mutually desire to modify said agreement as hereinafter provided.

Now, therefore, in consideration of the premises and of other good and valuable considerations, receipt of which [fol. 1852] is mutually acknowledged, the parties hereto agree that said agreement is from the date hereof modified as follows:

1. Paragraph 3 is amended by changing the period at the end thereof to a comma and adding the following:

"provided, Licensee desires such Letters Patent added to the Schedules A and B. And it is agreed that no additions shall be made to Schedules A and B without specific consent in writing by Licensee. Licensor shall give notice in writing to Licensee of any patents which Licensor proposes to add to Schedules A or B, and Licensee shall have thirty (30) days from the date of such notice within which to signify

whether or not it desires to have such further patents added to Schedules A or B."

2. Paragraph 4 is amended by adding thereto the following:

"Licensor agrees not to quote to the trade any amended or altered minimum prices until the expiration of fourteen (14) days following a written notice to Licensee of such amended or altered prices. And it is further agreed that when no minimum price is established by Licensor, after receipt of a request from Licensee for the establishment of such minimum prices, and Licensee shall proceed to enter into contracts for the sale of articles, the prices of which are not specified by Schedule C, then upon any subsequent [fol. 1853] fixing of minimum prices by Licensor, Licensee shall be free to fill all contracts for such articles previously entered into at the prices therein specified. If Licensor shall deliberately not establish a minimum price within one (1) year of the receipt of request from Licensee, the item shall remain unrestricted as to prices thereafter provided that, should Licensor fail to so establish a minimum price for any particular type, size, construction or embodiment of crown seals upon the request of any Licensee other than this Licensee, then this Licensee shall likewise be free to sell any such crown seals without price restriction."

3. Paragraph 7 is cancelled and the following paragraph is substituted therefor:

"Licensee agrees to pay to Licensor a royalty at the rate of three quarters of a cent (¾ of 1¢) per gross on all net sales of crown seals manufactured and shipped hereunder when the price fixed for the particular type (paper, aluminum, tin) spot crowns by Schedule 'C' under the heading 'Base Sales Prices—Two Color Composition Disc Crowns With Spots As Indicated' for shipments of 30,000 gross (car load lots) shall be twenty cents (20¢) or over, and a royalty of one-half cent (½ of 1¢) per gross on all such sales when the price fixed by Schedule "C" under the same heading for such shipments shall be under twenty cents (20¢) per gross, [fol. 1854] the royalty to be calculated on the net sales reported as provided for in Paragraph 6 and to be paid to the Licensor when rendering said reports. The price fixed by Schedule "C" for shipments of 30,000 gross lots shall deter-

mine the rate of royalty, regardless of the price to particular classes of consumers, i. e., small consumers or large (300,000 gross per year or more) consumers. Royalties shall be calculated separately on each type of spot (e. g., aluminum, paper, tin).

4. Paragraph 9 of the agreement is amended by inserting in line 12 the word "promptly" before "with."

5. Paragraph 11 is amended by cancelling in line 18 the word "mailing" and substituting "receipt."

6. Paragraph 15 (b) is amended by cancelling the last clause "whether this license thereafter continue in force or not" and substituting:

"so long as this license shall continue in force. And it is agreed that upon termination of this license, Licensee shall be in the same position, insofar, as its rights to question validity or scope of any of the patents is concerned, as though the license had never been made."

7. Substitute for Schedules "A" and "B" the following:

[fol. 1855] Schedule "A"

No. 1,899,782, Warth, February 28, 1933

Schedule "B"

No. 1,339,066, McManus, May 4, 1920;
No. 1,867,637, Warth, July 19, 1932;
No. 1,899,783, Warth, February 28, 1933;
No. 1,899,784, Warth, February 28, 1933;
No. 1,908,498, Warth, May 9, 1933;
Re. No. 19,117, Warth, March 20, 1934;
No. 1,956,481, Warth, April 24, 1934;
No. 1,967,195, Warth, July 17, 1934.

8. It is further agreed that the aforesaid agreement, dated the — day of ——, 1933, shall continue to remain in force without change, except as above specified.

[fol. 1856] Agreement

This Agreement, made at New York, New York, this — day of May, 1933, between Crown Cork & Seal Company, Inc., a New York corporation, hereinafter termed "Licensor" and ——— ———, a —— corporation, hereinafter termed "Licensee"

Witnesseth: That

Whereas, Licensor is engaged in the manufacture and sale of crown seals, and is the owner of certain United States Letters Patent for inventions relating to materials for facing bottle caps and method of making the same as set forth in the Schedule hereunto attached and marked Exhibit A, and is the owner of certain patents and applications for patents on closures and methods of manufacturing closures, as set forth in the schedule hereunto attached and marked Exhibit B;

Whereas, Licensee desires to acquire certain license rights under the Letters Patent in Schedules A and B; and

Whereas, Licensor desires to grant such license rights subject to certain terms and conditions as hereinafter set forth;

Now, Therefore, in consideration of the premises, of the mutual promises hereinafter set forth and of good and valuable consideration the parties hereto have agreed and do hereby agree as follows:

[fol. 1857] 1. Licensor does hereby grant to Licensee a non-exclusive right and license upon the terms and conditions hereinafter set out, in connection with use of material for the facing of crown seals, and the employment of Licensor's improved methods in the manufacture of crown seals:

(a) To manufacture (or have manufactured), for use in crown seals, but not to sell except as part of a crown seal, the materials of Patent No. 1,899,782 of Schedule A; and

(b) Under the patents and applications of Schedule B, to employ the methods thereof in the manufacture of crown seals and to manufacture and sell crown seals covered thereby.

The aforesaid license is to remain in force throughout the United States, its territories and possessions during a

period of time in which there may continue in force any Letters Patent (a) identified in said Schedules A or B; (b) issued upon the application for Letters Patent listed in Schedule B, and (c) issued upon any further or additional inventions or improvements owned by or coming into the possession of Licensor and added to said schedules as hereinafter provided, unless this license is sooner terminated, as hereinafter provided for, provided that Licensee shall at all times observe, perform and abide by the provisos, terms and conditions of this instrument and its covenants and agreements therein set forth and in the event [fol. 1858] of breach by Licensee, notice must be given Licensee by Licensor in order to effect cancellation of this agreement as hereinafter provided.

2. Licensor agrees to add to said Schedules any and all Letters Patent of the United States hereafter owned or controlled by it, or under which it may acquire the right to grant licenses without the payment by Licensor of royalty, provided such patents cover improvements (a) in materials for facing or spotting the cushion disks of crown seals or (b) in materials for adhesively uniting such facing materials to the cushion disks of crown seals or (c) in methods of uniting facing materials to the cushion disks of crown seals. In the event that Licensor acquires the right to grant licenses under patents of the aforesaid character, but must pay royalties or compensation to others for use of such patented inventions, Licensor shall include the same in schedule "C" as above set forth, provided Licensee shall pay to Licensor, in addition to the royalty herein specified, the amounts due from Licensor to others because of Licensee's use of such patented inventions. No such additional royalties shall be payable hereunder, however, if the said Letters Patent referred to in this Paragraph 2 be acquired, or the right to license under them be acquired, by Licensor from any of its officers or employees.

3. Licensor hereby agrees that when it may come to own or control or have the right to grant licenses or sub-licenses under any improvement Letters Patent as defined in Paragraph 2, it will immediately notify Licensee, and Licensee [fol. 1859] shall be immediately entitled to utilize the same upon the same terms and conditions as the Letters Patent now listed in Schedules A and B without payment of additional royalty except as provided in Paragraph 2. The

Licensor will formally include such Letters Patent in the Schedules A and B hereto attached as such license rights accrue to Licensee.

4. It is a limitation and condition of this license, however, that Licensee is licensed and authorized, under the Letters Patent for which this license is granted, to sell the crown seals manufactured hereunder (and upon which royalty is to be paid as a consideration for this license) at prices not less than the minimum prices established by Licensor by current bona fide price quotations to its trade for corresponding crown seals. Licensor shall promptly from time to time advise Licensee of the minimum prices thus established. In case no minimum prices are so established as to any particular type, size, construction or embodiment of crown seals, the Licensee shall request the establishment of a minimum price therefor and if the Licensor fails to do so within 14 days following the receipt of such request, this license shall be without price restriction as to such particular product until the establishment of a minimum price therefor. It is agreed that the present minimum prices are those set forth in Schedule C hereto attached and made part hereof. The minimum prices set forth in Schedule C may be amended or altered from time to time upon fourteen (14) days advance written notice to Licensee.

[fol. 1860] 5. Licensee agrees to keep in the United States, full, true and accurate records and books of account of crown seals manufactured and sold under this license. A duly Certified Public Accountant appointed by Licensor and at its expense, shall have access to said records and books of account at all reasonable times during business hours. If the accountant find that the Licensee's royalty payments and reports have been correct, then the accountant shall so report to Licensor but shall not disclose to Licensor or any one else any information derived from Licensee's books; but if the accountant find any discrepancy between Licensee's books and its reports or royalty payments, then the accountant shall be entitled to report to Licensor such information derived from any source as in the discretion of the accountant may be necessary to advise the Licensor of all facts pertinent to the amount and character of such discrepancies and the reason therefor, and only such information shall be disclosed.

6. Licensee agrees to make monthly reports to Licensor, not later than the 25th day of each month of each year while this license continues in force, setting forth therein the number of crown seals sold hereunder during the preceding calendar month in terms of net sales, i. e., shipped sales without deduction of cash discount but less returns and less cost of freight equalization, and less warehouse differential as set forth in Schedule C, and less defective goods allowances not exceeding one (1) per cent. of shipped sales.

7. Licensee agrees to pay to Licensor a royalty at the rate of five per cent. (5%) of all net sales of crown seals [fol. 1861] manufactured and shipped hereunder, the royalty to be calculated on the net sales reported as provided for in Paragraph 6 and to be paid to the Licensor when rendering said reports.

8. Licensor agrees that it shall be sufficient patent marking to place upon cases containing the licensed crown seals the numbers of the patents appearing in Schedules A and B, and the Licensee agrees so to do.

9. Licensor agrees that it will not grant any license to any other person, firm or corporation engaged in the manufacture and/or sale of crown seals for the manufacture and sale of crown seals under the Letters Patent at any time forming a part of Schedules A or B hereof upon terms more favorable than those herein provided, and Licensee may at its option substitute in this license and terms in any subsequent licenses under said Letters Patent which it believes to be more favorable. In order that Licensee may determine whether other licenses contain more favorable terms, Licensor covenants and agrees to furnish Licensee with a true copy of all licenses granted others for the manufacture or sale of crown seals under said Letters Patent or any of them.

10. Licensor agrees to maintain the Letters Patent under which this license is granted and to protect the same against infringement by taking effective action by suit, license or otherwise within reasonable time upon notice of such infringement.

[fol. 1862] 11. In the event Licensee breach any of the provisions of this agreement on its part to be performed,

Licensor may give notice thereof to Licensee, and in the event said breach be continued, or repeated after such notice, Licensor may cancel the agreement forthwith upon written notice. Licensee shall have the privilege of cancelling this agreement at any time after September thirty, nineteen hundred thirty-four (September 30, 1934) upon thirty (30) days written notice in advance of the date such cancellation is to take effect. Licensee shall have the right to cancel this agreement on thirty (30) days written notice to Licensor at any time prior to September thirty, nineteen hundred thirty-four (September 30, 1934) or thereafter should Licensor lower those sales prices originally established in the attached Schedule C and designated as "Base Sales Prices," provided however that should Licensee fail to give notice of cancellation within fourteen (14) days following the mailing of the notice of the lowering of such prices, the lowered prices shall be deemed to have been accepted by Licensee. Deliveries after cancellation, whether by Licensor or Licensee, on contracts made before cancellation, shall be subject to the specified royalty and shall be billed at not less than the prices of Schedules C as it existed at the date of cancellation, or at the prices of Schedule C as it existed at the date on which the contracts were written, whichever price is lower.

12. So long as this agreement be in effect, Licensee agrees not to contest the validity of any of the patents licensed [fol. 1863] hereunder nor to aid or assist others directly or indirectly in contesting their validity.

13. In the event Licensor bring suit against any third party for infringement of any of the Letters Patent herein licensed, Licensee agrees to assist Licensor by giving any evidence that Licensee may have knowledge of to be used in the prosecution of such suit to the extent to which Licensee is reasonably able, but in no event shall Licensee be required to undertake any expense in connection with such suit.

14. Licensor undertakes and agrees to save Licensee harmless and indemnify it against patent infringement by reason of Licensee's manufacture, sale or use of the articles, or Licensee's practice of the methods, covered by the Letters Patent herein licensed.

15(a) The obligation of Licensee to pay royalty as to any of the Letters Patent herein licensed shall cease and determine upon such Letters Patent being declared invalid, or so limited as not to cover Licensee's manufacture as then carried out, by the Supreme Court of the United States or a lesser court whose decision is not reversed upon appeal or review.

(b) It is agreed that if in a suit by Licensor against an alleged infringer, a court of final jurisdiction or a lower court from whose decision no appeal is taken, shall declare said Letters Patent, or any of them, invalid or limited, then said Letters Patent shall, as between Licensor and Licensee, be interpreted in accordance with the construction given to said Letters Patent in said decision, whether this license thereafter continue in force or not.

[fol. 1864] 16. This agreement and each of the terms thereof shall inure to the benefit of and be binding upon the parties hereto, their successors and subsidiaries. No right of assignment to any third party other than subsidiaries shall attach hereto on the part of either party except upon written approval by the other party.

17. Any notices provided in this agreement shall be served by either party to the other by registered mail addressed to the other party at its last known address.

18. This agreement shall at all times and places be interpreted in accordance with the laws of the State of New York.

19. The Licensor and Licensee agree that all claims or penalties for past infringements committed or alleged to have been committed by the Licensee in respect to the patents contained in Schedules A and B shall be forever waived and cancelled upon the execution of this agreement.

20. It is agreed that, as between Licensor and Licensee, Licensee may procure materials, whether patented or not, for use in crown seals covered by the Letters Patent for which this license is granted, from any sources it may desire, and no royalty other than or additional to that herein provided shall accrue to Licensor from any source of supply of Licensee by reason of such source of supply manufacturing or processing for, or supplying to, Licensee, mate-

rials for use in crown seals covered by any of the Letters Patent under which this license is granted.

[fol. 1865] 21. The Licensor and Licensee agree that as to contracts entered into before May one nineteen hundred thirty-three (May 1, 1933) shipments thereon prior to September thirty nineteen hundred thirty-three (September 30, 1933), shall not be subject to payment of any royalty or to Schedule C, but otherwise shall be subject to the terms of this agreement and shipments thereon after September thirty nineteen hundred thirty-three (September 30, 1933) shall not be subject to Schedule C, but otherwise shall be subject to the terms of this agreement, including the payment of the royalties specified.

22. Any of the rights or obligations granted or undertaken by this agreement may be delegated by Licensee to its subsidiaries owned or controlled by Licensee, but the sharing or delegation of any such right or obligation shall not relieve the sharing or delegating party from performance hereunder.

In Witness Whereof, the parties hereto have caused this agreement to be executed in duplicate for them and in their names by their respective officers thereunto duly authorized, and their corporate seals to be affixed, on the day and year first above written.

Jacksonville, Fla.	¾¢ " "	Salisbury, N. C.	1½¢ " "

Licensor will specify differentials for any additional branch or warehouse points upon request of Licensees.

[fol. 1868] DEFENDANT'S EXHIBIT PPPP

Oct. 10th, 1930.

Crown Cork & Seal Co., Baltimore, Md.

Att. Mr. N. Vinson, Vice President, & Genl. Sales Mgr.

MY DEAR MR. VINSON:

I just had confirmation through a very reliable source, of reports which have lately been brought to my attention.

It seems that your Chicago representative has recently advised the trade there that all crown manufacturers have to purchase their aluminum center crowns as well as their composition cork disc supplies from the Crown Cork & Seal Co. of Baltimore.

I believe that your firm will not permit such untruthful statements to be made in the trade, and therefore consider it my duty to bring this to your attention.

With best personal regards, I am,

Cordially yours, Ferdinand Gutmann & Co.

FG:CS.

The Crown Cork and Seal Company

Baltimore, U. S. A.

October 13, 1930.

Mr. Ferdinand Gutmann, President, Ferdinand Gutmann & Co., Bush Terminal No. 19, Brooklyn, N. Y.

MY DEAR MR. GUTMANN:

This will acknowledge yours of the 10th and regret very much to learn of the statements attributed to our Chicago representation. In no sense will we permit remarks on the part of our men that might be derogatory to our competitors.

Please be assured that this will be carefully investigated and thanking you very much for bringing this to the writer's attention, we are with all good wishes

Yours very truly, (Signed) W. Vinson, Vice President.

[fol. 1871] Defendant's Exhibit RRRR

Statement of Warth, Filed Jan. 19, 1931, Approved Jan. 24, 1931

In the United States Patent Office

Interference No. 60,931

Albin H. Warth

v.

Louvern G. Lange

Preliminary Statement of Albin H. Warth

District of Columbia, ss:

Albin H. Warth, being first duly sworn, deposes and says that he is a party to the above entitled interference involving his application, Serial No. 360,895, filed May 5, 1929, and a patent to Louvern G. Lange, No. 1,779,884.

That he conceived the invention defined by the several counts on or about the first day of July, 1915.

That he first disclosed to others the said invention on or about the first day of July, 1915.

That he made first written description of the said invention on or about the first day of July, 1915.

That first drawings of the invention were made on or about the first day of August, 1926.

That the invention was reduced to practice by the manu-

[fol. 1872] facture and use of material of the character de-

fined in each count on or about the first day of June, 1915, at Baltimore, Maryland.

That the material of the character defined in each count has been made in large quantities since June 1, 1915.

Albin H. Warth.

Sworn to and subscribed before me, a Notary Public, this 16th day of Jan., 1931. Catharine S. Wilton, Notary Public, D. C. (Seal.)

DEFENDANT'S EXHIBIT SSSS

IN THE UNITED STATES PATENT OFFICE

Interference No. 60,931

LANGE

vs.

WARTH

DISTRICT OF COLUMBIA, ss:

John J. Darby, being first duly sworn, deposes and says:

That he is a member of the firm of Cushman, Bryant, Darby and Cushman, attorneys for the party Warth.

[fol. 1873] That deponent has been in immediate charge of this interference on behalf of the party Warth and attended the taking of testimony for the party Lange at the office of Messrs. Pennie, Davis, Marvin & Edmonds, in New York City on March 30th, March 31st, and April 1st, 1932.

That prior to March 30th, deponent had orally informed attorneys for Lange that deponent would stipulate the taking of the testimony stenographically instead of directly on the typewriter, provided deponent was furnished each day with a copy of the testimony; that this statement was repeated to attorneys for Lange at the beginning of the taking of testimony on March 30, 1932, whereupon counsel for Lange agreed to do so and stated that in order to do this, he would arrange to have the testimony taken by two stenographers in the employ of Messrs. Pennie, Davis, Marvin & Edmonds, under the supervision of Marie Loftus, a Notary Public who was also in the employ of Messrs. Pennie, Davis, Marvin & Edmonds.

That on both March 30th and March 31st, a copy of the testimony thus far transcribed was furnished deponent in

accordance with this agreement, and that deponent, throughout the taking of testimony, made many personal notes in the interest of the party Warth on said copy of the testimony.

That attorneys for Lange completed taking testimony about noon on April 1st, and informed deponent that no further testimony would be taken on behalf of the party Lange.

That deponent thereupon requested one of the stenographers under the supervision of the Notary, and without [fol. 1874] reference to attorneys for Lange, to add to deponent's copy of the testimony the few pages which had not been transcribed and to mail this copy, with copies of the exhibits, promptly to deponent at his offices in Washington, D. C., and that said stenographer agreed to do this.

That the statements made in deponent's affidavit filed April 5, 1932, as well as in the motion to dissolve, were based largely upon the testimony given by the party Lange, since the party Lange had furnished materials to the Crown Cork & Seal Company during the years in question and had confirmed deponent's suspicions, previously stated to attorneys for Lange, that material made by the party Lange and used for many years by the Crown Cork & Seal Company responded to the single claim in issue.

That when deponent made his affidavit filed with the motion to dissolve this interference, deponent regarded his copy of the testimony which counsel for Lange had agreed to furnish and which the stenographer had promised to forward promptly to deponent, as evidence constructively in the possession of deponent, and, therefore, constituting "proofs available" to the party Warth as set forth in deponent's affidavit.

That since the dissolution of this interference deponent has made repeated efforts to have returned in completed form his copy of the testimony bearing deponent's notes, with copies of the exhibits, but that both the Notary and attorneys for the party Lange decline to return said copy of the testimony in either complete or incomplete form.

That deponent's affidavit in support of the motion to dissolve was based largely upon the testimony, copy of which [fol. 1875] Lange's counsel agreed to furnish deponent; said affidavit was, therefore, made with the understanding by deponent that the agreement entered into would be adhered to and that the Notary or counsel for Lange would return deponent's papers and notes.

That deponent would not have permitted the testimony to be taken by Lange in stenographic form had deponent not been assured of a complete copy of the proceedings at the termination of each day; that a copy of the major portion of the testimony was delivered to deponent pursuant to this agreement, but the same is now retained by counsel for Lange notwithstanding demands made upon him and the Notary that the same be returned.

That deponent believes that the Notary has delivered deponent's copy and personal notes of the testimony to counsel for Lange, although given no authority to do so, and that counsel for Lange have definitely declined to return the same or to furnish any copy of the testimony or copies of the exhibits.

That deponent, therefore, filed the motion to dissolve and the supporting affidavit under the belief that the Lange testimony constituted part of the proofs available to Warth in connection with the question of public use, and that in view of the refusal of counsel for Lange to deliver copy of this testimony to counsel for Warth, deponent's statements in connection with the motion to dissolve were largely in error since such proofs are not, in fact, available to deponent's client because of the refusal of the Notary and attorneys for Lange to return deponent's papers and notes or to furnish a copy of said testimony as stipulated and agreed.

[fol. 1876] That deponent based his affidavit in support of the motion to dissolve largely upon the testimony and admissions by the party Lange.

That the letters attached hereto are copies of correspondence between deponent and the Notary and between deponent and attorneys for Lange.

That deponent did state to attorneys for Lange on or about March 2nd, that deponent felt the subject matter of the claim had probably been in public use, but that prior to the admissions by the party Lange in the course of his testimony, deponent did not feel that he had available any clear proof of such public use.

Further deponent sayeth not.

John J. Darby.

Subscribed and sworn to before me, a Notary Public, this 20th day of May, 1932. Theresa Buckhantz, Notary Public, D. C. (Seal.)

[fol. 1877] DEFENDANT'S EXHIBIT UUUU

License Agreement

This agreement entered into this — day of December, 1933, by and between Crown Cork & Seal Company, Inc., a corporation of New York, hereinafter termed first party and Louvern G. Lange of East Rutherford, New Jersey, hereinafter termed second party, witnesseth:

Whereas, first party is the owner of United States Letters Patent, 1,899,782, granted February 28th, 1933 and

Whereas, second party desires to acquire the right to manufacture and sell adhesive coated paper and foil under said patent, and,

Whereas, first party is willing to grant such right subject to the condition that material made under and in accordance with said patent for the center spotting of closure caps shall be sold by second party only to those licensed by first party to manufacture and sell caps.

Now Therefore, in consideration of Ten Dollars ($10.00) each to the other in hand paid, receipt of which is hereby mutually acknowledged, and in consideration of the mutual agreements herein set forth as well as other good and valuable consideration, the parties hereto agree as follows:

1. First party hereby grants to second party the right to manufacture coated paper and foil under United States Letters Patent 1,899,782, granted February 28th, 1933, provided that when such material shall be sold for the purpose [fol. 1878] of center spotting closure caps, it shall only be sold to persons duly licensed by first party to manufacture and sell caps containing material of the character covered by said patent and also licensed under first party's patents number 1,339,066, granted May 4th, 1920.—1,788,260, granted January 6th, 1932,—1,867,637, granted July 19th, 1932,—1,899,783, granted February 28th, 1933 and 1,889,784, granted February 28th, 1933.

2. Second party covenants that material made and sold under this license shall not be sold to manufacturers of crown seal and/or for center spotting of crown seals, or other center spot closure, except and unless the purchasers of such materials are duly licensed by first party under first party's Patent No. 1,899,782, granted February 28th, 1933 and under the first party's patents mentioned in paragraph numbered (1) supra.

3. First party further grants to second party a free license to manufacture and sell to anyone other than crown seal manufacturers the varnish and adhesive coated paper and foil covered by United States Letters Patent 1,899,782, dated February 28th, 1933, for other than center spotting purposes. By "center spot" as used in this agreement is meant a facing disposed substantially centrally within a cap of less diameter than the diameter of the inner surface which contacts with the top or lip of the vessel to which the cap is applied. By "center spotting" is meant the step of applying a center spot.

[fol. 1879] 4. The aforesaid license is to run for the life of the said patent 1,899,782 unless sooner terminated. The said license shall be terminable by second party upon sixty (60) days notice in writing to the first party and upon termination of the license no estoppel shall exist against second party to contest said patent in any way because of second-party's having entered into this license agreement. The license shall be terminable by first party only in the event second party shall fail to live up to the provisions of this agreement or to any of the provisions of separate agreements entered into with first party this — day of December, 1933.

5. This license is non-exclusive and is not assignable, except that second party may permit the Standard Insulation Company, a corporation of New Jersey located in East Rutherford, New Jersey to operate thereunder in second party's place and stead.

—— ——, Second Party.

Witness: —— ——.

Crown Cork & Seal Company, Inc., First Party, By —— ——.

Attest: —— ——, Secretary.

[fol. 1880] License Agreement

This agreement entered into this — day of December, 1933 by and between Crown Cork & Seal Company, Inc., a corporation of New York, hereinafter termed first party and Louvern G. Lange of East Rutherford, New Jersey, hereinafter termed second party, witnesseth:

Whereas, first party has by separate agreement granted to second party a license under United States Letters Patent No. 1,899,782, and

Whereas, the parties hereto are involved in a number of controversies which both parties desire to settle by agreement;

Now Therefore, in consideration of the aforesaid separate license agreement under said Letters Patent, and in consideration of the payment of ten dollars ($10.00) each to the other in hand paid, receipt of which is hereby mutually acknowledged and other good and valuable considerations, the parties hereto agree as follows:

1. Second party shall take no action in and shall permit to go by default judgment to first party a certain conflict proceeding now pending in the Dominion of Canada and involving first party's application for Canadian patent Serial No. 371,376, and second party's application for Canadian patent Serial No. 364,272; it is agreed that first party shall file a statement of date of invention and upon issuance of an order to second party requiring the latter to file a date of invention the latter shall fail to do so and shall [fol. 1881] permit entry of judgment by virtue of such failure in favor of first party.

2. Second party shall cause his attorneys, Pennie, Davis, Marvin & Edmonds of New York City to deliver to first party forthwith upon the signing of this agreement a complete copy of testimony taken in a certain interference proceeding involving second party's patent No. 1,779,884, including a partial copy bearing notes made by first party's attorneys, and also photostatic copies of all exhibits introduced in evidence; the latter to be prepared at first party's expense. Second party agrees that should his said attorneys decline to deliver the said papers, he will co-operate with first party to force delivery of said papers.

3. Second party agrees to sell and first party agrees to buy from second party the latter's German party No. 557,780, dated August 27, 1932, for the sum of five hundred and ninety-five ($595.00) dollars; all necessary papers for formal transfer of title of said patent to first party to be prepared at the expense of first party, and the same to be executed by second party upon tender of the payment of said sum. Second party agrees not to oppose a pending request by first party to inspect the application file of said German patent.

4. Second party shall be given by first party in the Dominion of Canada and Germany rights corresponding to the rights given second party by first party in the United States and subject to the same conditions, including restriction to sale of the material to licensees of first party [fol. 1882] or of its assigns.

Witness: —— ——. —— ——, Second Party.

[fol. 1883] DEFENDANT'S EXHIBIT VVVV

At a stated term of the District Court of the United States in and for the Southern District of New York, held in the United States Court House and Post Office Building, Borough of Manhattan, City and State of New York, this 31st day of January, 1934.

Present: Honorable William Bondy, U. S. District Judge.

E. 72-52

CROWN CORK AND SEAL CO., INC., and ALBIN H. WARTH, Plaintiffs,

vs.

WILLIAM H. DAVIS, ARBA B. MARVIN, DEAN S. EDMONDS, W. Brown Morton, Merton W. Sage, Willis H. Taylor, Jr., Ernest H. Merchant, Morris D. Jackson, R. Morton Adams, Raymond F. Adams, Leslie B. Young, Marie Loftus, Defendants

Consent Order

This cause having come on to be heard at this Term of Court for the entry of this order, and all parties herein, [fol. 1884] by their respective attorneys, having consented thereto, it is, upon consideration thereof,

Ordered, Adjudged and Decreed:

1. That the sealed envelope containing the original transcript and exhibits of the party Louvern G. Lange, in the

Patent Office Interference #60,931, together with copies of the same, including that portion of a copy of the transcript of the testimony containing pencilled notes by John J. Darby, and stenographic notes of the testimony now under seal in the custody of the clerk of this Court be returned to John F. Neary (or his representative), the solicitor for the Defendants herein.

2. That in accordance with paragraph 2 of the agreement, heretofore entered into by and between Crown Cork and Seal Company, Inc., party of the first part and L. G. Lange, party of the second part, the firm of Pennie, Davis, Marvin & Edmonds, of which certain of the Defendants herein are members, shall deliver forthwith, upon the signing of said agreement, a complete copy of the testimony taken in a certain interference proceeding involving Lange patent #1,779,884, including a partial copy bearing notes made by Crown Cork and Seal Company's attorneys, and also photostatic copies of all exhibits introduced in evidence; the latter to be prepared at the expense of Crown Cork and Seal Company, Plaintiff herein.

[fol. 1885] 3. That this action be and the same is hereby dismissed with prejudice, but without damages or cost to either party.

Wm. Bondy, U. S. District Judge.

Approved as to form and consented to:
Thomas Ewing, Solicitor for Plaintiffs. John F. Neary by C. Di Martino, Solicitor for Defendants.

Envelope described above Received this 1st day February, 1934.

John F. Neary, by C. Di Martino, Solicitor for Defendants.

DEFENDANT'S EXHIBIT X X X X

SPOT CROWNS

ANNOUNCEMENT

TO THE BOTTLING AND BREWING INDUSTRIES:

The conclusion of litigation involving spot crown patents (paper, tinfoil and aluminum foil) has resulted in the award to the Crown Cork & Seal Company, Inc. of the following patents:

1,899,782	granted	February 28, 1933
1,899,783	granted	February 28, 1933
1,899,784	granted	February 28, 1933
1,908,498	granted	May . . . 9, 1933

The above patents were issued after the Crown Cork & Seal Company, Inc. had established its priority of invention in an interference proceeding in the United States Patent Office.

The above patents supplement the protection granted under previously issued Crown Cork & Seal Company, Inc. spot crown patents as follows:

1,339,066	granted	May 4, 1920
1,788,260	granted	January 6, 1931
1,867,637	granted	July 19, 1932

These patents grant to Crown Cork & Seal Company, Inc., and its licensees, the exclusive right to manufacture and sell spot crowns (paper, tinfoil or aluminum foil), and the exclusive right to the methods of manufacturing "spot" materials and spot crowns, as described in these patents.

All crown manufacturers have been notified of the issuance of the patents, and they have also been advised that if they desire to manufacture aluminum foil spot, tinfoil spot and paper spot crowns, the Crown Cork & Seal Company, Inc. is prepared to issue licenses granting them the right to manufacture and sell under these patents. Many crown manufacturers have already obtained such licenses.

Spot crowns, as covered by these patents, were developed at very great expense to the Crown Cork & Seal Company, Inc. and while willing to license other crown manufacturers under these patents, it is their intention to rigidly enforce them.

Therefore, the bottling and brewing trades are advised that they should purchase spot crowns either from Crown Cork & Seal Company, Inc., or from other manufacturers licensed under its spot crown patents.

CROWN CORK & SEAL CO. Baltimore Md.

PAGE

[fol. 1887] DEFENDANT'S EXHIBIT YYYY

IN THE UNITED STATES PATENT OFFICE

Interference No. 66,201

WARTH

vs.

JOHNSON

Record for Albin H. Warth

Declaration

The case, above referred to, is forwarded to the Examiner of Interferences because it is adjudged to interfere with others, hereafter specified. The question of priority will be determined in conformity with the Rules. The interference will be identified as No. 66201 on or before May 15, 1933, the statement demanded by rule 110 must be sealed up and filed with the subject of invention, and name of party filing it, indorsed on the envelope. The subject-matter involved in the interference is

Count 1. The method of assembling linings for sealing pads in receptacle closure caps, consisting in providing caps with sealing pads therein and a web of lining material arranged with an adhesive surface non-viscous at normal temperature, heating the pads in the caps, and severing linings [fol. 1888] from the web of lining material and assembling the linings as they are severed from the web in the caps with the adhesive surface in contact with the heated pads to render the adhesive viscous and effect adhesion of the linings to the pads.

Count 2. The method of assembling linings for sealing pads in receptacle closure caps, consisting in providing caps, with sealing pads therein and a web of lining material arranged with an adhesive surface non-viscous at normal temperature, heating the pads in the caps, severing linings from the web of lining material and assembling the linings as they are severed from the web in the caps with the adhesive surface in contact with the heated pads to render the adhesive viscous and effect adhesion of the linings to the pads; and then placing the linings in the caps under

1615

heat and pressure to effect an intimate adhesion between the linings and pads.

Count 3. The method of assembling linings for sealing pads in receptacle closure caps, consisting in providing caps with sealing pads therein and a web of lining material arranged with an adhesive surface non-viscous at normal temperature, heating the pads in the caps, severing the linings from the web of lining material and assembling the linings as they are severed from the web in the caps with the adhesive surface in contact with the heated pads to render the adhesive viscous and effect adhesion of the linings to the pads, then placing the linings in the caps under heat and pressure to effect an intimate adhesion between [fol. 1889] the linings and pads, and then placing the linings assembled in the caps under pressure during the cooling thereof.

The interference involves your application above identified and a patent, No. 1,852,578, granted April 5, 1932, for Method and Apparatus for Assembling Linings in Receptacle Closure Caps, Serial No. 409,793, filed November 26, 1929, by John A. Johnson, whose post office address is 84-16-86th Street, Woodhaven, N. Y., and whose attorney is John O. Seifert, 277 Broadway, New York, N. Y.

The relation of the counts of the interference to the claims of the respective parties is as follows:

Counts	Warth	Johnson
1	1	28
2	2	29
3	3	30

Counts Compared.

——— ———, Examiner, Division 14.

In the United States Patent Office

Interference No. 66,201

Warth

vs.

Johnson

The parties hereto, by counsel, stipulate as follows:

(1) That the accompanying affidavits of Frank L. Lloyd, H. Monroe Humason, and Albin H. Warth may be received

[fol. 1890] in support of the case of the party Warth, with the full force and effect of testimony regularly taken, and that said affidavits may be used by the party Warth on appeal to the Board of Appeals and/or the Court of Customs and Patent Appeals.

(2) That at final hearing the only question to be decided, is whether those portions of the Warth specification of his case in interference (Serial No. 664,410) and which also appeared in the earlier filed applications referred to in the second paragraph of the Warth specification in interference, support any or all of the claims in interference.

(3) That if the Examiner of Interferences or a higher tribunal on appeal determines that said portions of the specification do support the claims or any of them, the party Warth shall be entitled to and shall receive an award of priority as to such claims. And on the contrary, if in the event of a finding that such portions of the application do not support the claims in interference or any of them, the party Johnson shall be entitled to, and shall receive an award of priority.

John O. Seifert, Attorney for Johnson. Cushman, Darby & Cushman, Attorneys for Warth.

March 16, 1934.

[fol. 1891] IN THE UNITED STATES PATENT OFFICE

Interference No. 66,201

WARTH

vs.

JOHNSON

Affidavit

STATE OF MARYLAND,
City of Baltimore, ss:

Albin H. Warth, being first duly sworn, deposes and says:

I am the Albin H. Warth who filed on January 7, 1927, an application Serial No. 159,743, entitled "Process of Pro-

ducing Closures," and whose application Serial No. 664,410, filed April 4, 1923, is involved in the above entitled interference.

For approximately seventeen (17) years I have been employed by the Crown Cork & Seal Company, Inc., and its predecessor in Baltimore, Maryland, and for the same period of time have been continuously engaged in technical work connected with the manufacture of caps of the "crown" type.

"Crown" caps may be roughly divided into two classes, namely, (1) "center spot" caps in which a small disc facing of less diameter than the cork disc or cushion is adhesively united to the cushion disc, and (2) caps in which the cushion disc is left entirely exposed.

[fol. 1892] In the manufacture of center spot caps, it has always been the practice first to manufacture what is known as an "assembled crown." That is to say, by a suitable machine the metal shell has inserted and adhesively fixed therein a cork disc or cushion which may be either natural cork or cork composition. This product has always been known in the trade as an "assembled crown."

In the manufacture of "center spot" crowns, the assembled crowns are then introduced into a machine by which the "center spot" or facing is adhesively affixed to the cushion disc of the assembled crown.

I have carefully read the following portion of the specification of my original application filed January 7, 1927, Serial No. 159,743:

> "At the time of assembly the coating material is softened to render it adhesive and the assembled unit is subjected to pressure. In carrying out the invention according to what is now considered the best practice the coating will be softened by heat after the crown is assembled. This may be accomplished in any suitable manner, as by a heated plunger or a plunger and heated table. The heat softens the coating and renders it adhesive and the pressure serves to unite the metal foil spot to the cork.
>
> * * * * * * *
>
> It may be desirable to secure the metal foil spot in position, prior to the heat and pressure steps, sufficiently to prevent dislodgement of the spot during any interval between assembling and final sticking. This may be accomplished,

[fol. 1893] for example, by preheating the assembled crown, to soften the coating, as soon as the metal foil spot is deposited. Or the coating may be softened by moistening slightly with a solvent, such as benzol. In either case the coating becomes tacky enough to hold the metal foil spot from getting out of position during ordinary passage through assembling apparatus."

The use of the term "assembled crown" in the clause "preheating the assembled crown" is correct. An "assembled crown" is now understood and always has been understood by me and by those familiar in the art to mean merely a metal shell of the crown type having a cushion disc deposited therein. Whenever I refer in the specification to the spotted crown, I refer to it as the "assembled *unit*." It will be noted that this expression is used throughout the specification. For example, the expression (p. 3, l. 12 et seq., "the assembled unit is then cooled and the cooling may advantageously be coupled with pressure etc.," illustrates that I clearly drew a distinction between the term "assembled crown" and the term "assembled unit."

The expression "assembled crown," as used in line 6 of the second paragraph above quoted, was used by me in the sense it is ordinarily used in the art. Ever since my association with the Crown Cork & Seal Company of Baltimore, over seventeen years ago, I, and everyone with whom I am acquainted in the crown cork industry, have used the expression "assembled crown" to refer simply to a cap consisting of a metal shell having the cork disc inserted and [fol. 1894] adhesively affixed in position. Since prior to 1919, these assembled crowns have been produced in the plant of the Crown Cork & Seal Company of Baltimore, Maryland, upon machines of the type disclosed in the patent to Goebel, No. 1,469,557, granted Oct. 2, 1923. It will be noted that the expression "assembled crown" is used repeatedly in the specification of the above noted patent in exactly the same sense it is employed by me. For example, note the following portions of the patent specification:

"In making closures of this type, according to one method, the shell, binding disk and sealing disk are assembled, the *assembled crown* is heated to soften the adhesive material, and the crown is subjected to pressure

and a cooling medium. It is to apparatus for *assembling crowns* of the type mentioned that the present invention relates." (Page 7, lines 18-26, emphasis ours.)

"Finally, the *assembled crown* is delivered to a heating and cooling wheel." (Page 1, lines 92-95, emphasis ours.)

The patented art includes numerous illustrations of the use of the expression "assembled crown" to designate exactly what I intended to designate in the above quoted portion of my specification. A few examples are the following:

Patent No. 1,402,780, McManus, Jan. 10, 1922, describes a machine for applying center spots to the cushion discs of crown caps. This patent repeatedly refers to the caps which are introduced into the machine to be spotted as "as-[fol. 1895] sembled caps." Note the following portions of the specifications: p. 2, l. 67 and p. 6, ll. 37-43. The portion of the specification last referred to reads as follows:

"In the form of the invention shown the protecting facing disk is applied after the cork or *other resilient disk has been assembled* with the metal part of the cap, and the details of the machine are so constructed as to adapt the machine to the handling of the *assembled caps.*" (Emphasis ours.)

Patent No. 1,574,913, McManus, March 2, 1926. This patent describes a machine for inserting cushion discs in crown caps. The machine is identified in the specification p. 1, l. 18 as a "cap assembling machine."

Patent No. 1,580,642, Binder, April 13, 1926. This patent describes a mechanism for assembling sealing discs with crown caps. The caps produced are described in the specification (p. 4, l. 49) as "*assembled crowns.*"

Patent No. 1,444,615, McManus, Feb. 6, 1923, describes a machine for performing the same function and the crown or cap produced thereby is identified in the specification (p. 5, l. 23) as an "assembled cap."

Patent No. 1,662,862, McManus, March 20, 1928, covers a delivery mechanism for a machine intended to assemble cushion discs with the metal shells of crown caps and the caps produced by the machine are identified as "assembled bottle caps" (specification p. 1, l. 11).

[fol. 1896] Patent No. 1,354,530, Angus, Oct. 5, 1920. The specification of this patent refers to a crown, which is fed

into a spotting machine in the manner described by me, as an "assembled crown." See p. 1, l. 18.

It has been the invariable practice in the art of manufacturing crown caps to identify machines for combing a cushion disc with a metal shell as "assembling machines" and to term the product of this machine an "assembled crown" or "assembled cap."

The quoted portion of the application was intended by me to describe a method which I fully disclosed prior to January 7, 1927, to the patent counsel who prepared the application, namely, H. M. Humason, Esq., of the firm of Philipp, Sawyer, Rice & Kennedy. Prior to January, 1927, I disclosed said process to Mr. Humason, both direct and through Mr. Frank L. Lloyd of Baltimore, Maryland, who for over seventeen (17) years has been associated with the Crown Cork & Seal Company, Inc., and its predecessor.

I refer particularly to the sentences of the specification (Serial No. 159,743 and Serial No. 664,410) which reads:

"This may be accomplished, for example, by preheating the assembled crown, to soften the coating, as soon as the metal foil spot is deposited. Or the coating may be softened by moistening slightly with a solvent, such as benzol."

The above disclosure was intended by me to describe alternative methods of insuring a sticking of the adhesively coated center spot to the cushion disc as soon as the spot is [fol. 1897] deposited. In the second method, the adhesive coating on the foil strip is pre-softened by moistening slightly with a solvent so that, as soon as the punched center spot falls on the cushion disc, it tends to stick thereto. The first method described in the preceding sentence involved the preheating of the assembled crowns which are fed into the spotting mechanism so that the pre-applied heat will soften the coating on the spot as soon as the spot is deposited on the cushion disc.

The foregoing was the meaning I intended to convey by the portions of the specification quoted. In other words, when I used the term "preheating the assembled crown," I meant only one thing, namely, that the assembled crowns being fed to the spotting mechanism had heat applied thereto prior to the deposition of the spot in order to effect sticking of the spot to the cushion disc "as soon as the metal foil spot is deposited." This prevents dislodgement

or moving of the spots from their exactly centered position. An exact centering of the spot on the cushion disc is absolutely essential in order that only a very narrow marginal portion will overlie the lip of the bottle and the greater portion of the width of the bottle lip entirely around the same may uniformly contact with the cushion disc.

This procedure was fully described by me to Mr. Frank L. Lloyd, and the portions of the specification above quoted were intended to convey an understanding of such procedure.

My attention has been called to the comma which appears after the word "coating" in the above quoted portion of the specification. It is my feeling that this comma does [fol. 1898] not make the sentence misleading, but if it does make possible any interpretation other than the one I intended, as above set forth, its presence is a typographical error which I have not heretofore noted. The words "as soon as," in my judgment, clearly qualify and relate to the softening of the coating and not to the heating. They mean, as was intended by me, that the assembled crown, i. e., the metal shell and cushion disc, is preheated so that as soon as the metal foil spot is deposited, the coating will be softened.

Further deponent sayeth not.

Albin H. Warth.

Sworn and subscribed to before me, a Notary Public, this 14th day of March, 1934. Florence M. Meckrotte, Notary Public. (Seal.)

WARTH

vs.

JOHNSON

Affidavit

STATE OF MARYLAND,
City of Baltimore, ss:

Frank L. Lloyd, being first duly sworn, deposes and says:

I am of legal age, and for twenty (20) years have been associated with the Crown Cork & Seal Company, Inc., of

[fol. 1899] Baltimore, Maryland, and its predecessor the Crown Cork & Seal Company of Baltimore City. In January, 1927, and for sometime prior to that date, I was chief engineer of the Crown Cork & Seal Company of Baltimore City. Among my duties was the handling of patent matters, including the transmission of disclosures for patent applications to the patent attorneys for the company who were at that time Philipp, Sawyer, Rice & Kennedy of New York City. Mr. H. M. Humason of that firm personally handled practically all of the patent work for my company.

Among the disclosures which I submitted to Mr. Humason was one which afforded a basis for an application of Albin H. Warth, Serial No. 159,743, filed January 7, 1927. I discussed the said application prior to its filing with Mr. Humason, and the said Albin H. Warth also discussed the same with him. Prior to the filing of this case among the other steps described therein, Albin H. Warth fully explained to me two steps which he had developed for the purpose of insuring that the center spot applied to the cushion disc is accurately centered the instant it is deposited on the cork disc in order that in the further steps of his method, the spot would not move from its centered position. I have read the accompanying affidavit of Albin H. Warth and know that the statements contained therein are true.

I have further read that portion of the specification which reads as follows:

"It may be desirable to secure the metal foil spot in position, prior to the heat and pressure steps, sufficiently to [fol. 1900] prevent dislodgement of the spot during any interval between assembling and final sticking. This may be accomplished, for example, by preheating the assembled crown, to soften the coating, as soon as the metal foil spot is deposited. Or the coating may be softened by moistening slightly with a solvent, such as benzol. In either case the coating becomes tacky enough to hold the metal foil spot from getting out of position during ordinary passage through assembling apparatus."

I understood from the explanation of the invention given by Dr. Warth prior to the filing of the application on January 7, 1927, and now understand from the above quoted portion of the specification, that the instantaneous sticking of the spot is obtained in two ways. First, the coating on

the foil strip may be softened by a solvent, whereby when the spot is punched therefrom and deposited on the cork, it is immediately struck in its accurately centered position. Second, a preheating method is employed. It was clear that the strip itself or the spot is not preheated. The language distinctly states that the step involves "preheating the assembled crown." An "assembled crown" has always meant in the crown industry and to anyone skilled in this art, simply a metal shell of the crown type having a cushion disc therein. It is distinguishable from an assembled "unit," such as is referred to in other parts of the Warth specification from which I have quoted above. It is evident that the term "assembled unit," as used in said specification, means an assembled crown having a center spot [fol. 1901] affixed to the cushion disc thereof. To use the preheating method, instead of a solvent, to obtain sticking "as soon as the metal foil spot is deposited, it is obvious from the language of the specification, in the light of common knowledge in the art of spot crown manufacture available prior to January, 1927, that the preheating is to be effected at some point or time prior to depositing the spot on the cushion disc. Otherwise, there would be no preheating; nor would there be preheating of an "assembled crown," as this term is understood in the art and evidently used in the specification.

The only reasonable interpretation which I place upon the sentence quoted is that the assembled crown, i. e., the shell with cushion disc therein, is preheated so that the applied heat will soften the coating "as soon as the metal foil spot is deposited."

The word "preheating," as used in the specification means to me, and in my judgment would mean to anyone skilled in the crown cap art, the application of heat before the spot is applied, particularly in view of the fact that the word "preheating" is used in connection with the application of heat to an "assembled crown." Delaying the application of heat until the spot is applied would not constitute "*preheating the assembled crown*," as these words are understood in the art.

Further deponent sayeth not. Frank L. Lloyd.

Subscribed and sworn to before me, a Notary Public, this 1st day of March, 1934. W. S. Brownley, Notary Public. (Seal.)

[fol. 1902] IN THE UNITED STATES PATENT OFFICE

Interference No. 66,201

WARTH

vs.

JOHNSON

Affidavit

STATE OF NEW YORK,
County of New York, ss:

H. Monroe Humason, being duly sworn, deposes and says:

I am 46 years of age and reside in New Canaan, Connecticut. Since July 1, 1927, I have been a member of the firm of Philipp, Sawyer, Rice & Kennedy, attorneys and counsellors at law, with offices at 220 Broadway, New York City and for over 11 years prior to that date I was employed by said firm as an assistant attorney. Said Philipp, Sawyer, Rice & Kennedy were for many years general patent counsel for Crown Cork & Seal Company of Baltimore City, predecessor of Crown Cork & Seal Co., Inc., and from about July, 1916, to about July, 1928, I personally prepared substantially all the patent applications of said Crown Cork & Seal Company of Baltimore City, under the general supervision of James Q. Rice, Esq., now deceased.

Among the applications so prepared by me was an application of Albin H. Warth, Serial No. 159,743, filed January 7, 1927.

[fol. 1903] About the end of 1930 prosecution of this Warth application was taken over by Cushman, Bryant & Darby (now Cushman, Darby & Cushman), since which time neither I nor my firm have had anything to do with the prosecution of said application or any divisional or related applications.

According to the Warth invention as disclosed to me, prior to the preparation of the application, Mr. Warth proposed to prevent dislodgment of the coated spot during any interval between the time the spot is assembled and the final sticking, which final sticking may be accomplished, for example, by heat and pressure. Two ways of attaining this end were proposed, one involving a preheating to soften the coating sufficiently to position the spot temporarily, the other involving moistening with a solvent to the same end.

This step of temporarily preventing dislodgment is set forth in the original application in the following paragraph:

"It may be desirable to secure the metal foil spot in position, prior to the heat and pressure steps, sufficiently to prevent dislodgment of the spot during any interval between assembling and final sticking. This may be accomplished, for example, by preheating the assembled crown, to soften the coating, as soon as the metal foil spot is deposited. Or the coating may be softened by moistening slightly with a solvent, such as benzol. In either case the coating becomes tacky enough to hold the metal foil spot from getting out of position during ordinary passage through assembling apparatus."

[fol. 1904] I refer particularly to the following sentence from that paragraph:

"This may be accomplished, for example, by preheating the assembled crown to soften the coating, as soon as the metal foil spot is deposited."

For convenience I shall here refer to the heating for temporarily preventing dislodgment as "preventive heating" as distinguished from final heating.

It is my opinion that the above quoted sentence should not be read and cannot properly be read to mean that the coating of the spot is given its temporary softening by preventive heating when and only when the spot has been deposited. On the contrary, it is my opinion that the sentence should be read and properly must be read to mean that the preventive heating of the crown is effected before the spot is deposited. Putting it another way, the words "as soon as" relate to the softening of the coating and not to the step of heating. Or, to paraphrase the sentence, it means: "This may be accomplished, for example, by heating the assembled crown before the spot is deposited, thereby to soften the coating of the spot as soon as the spot is deposited."

The reasons for the above opinion are as follows:

1. Since the avowed object, as stated in the quoted paragraph, is to prevent dislodgment of the spot between the time of depositing the spot and the time of final sticking, the word "preheating" of the crown logically, reasonably [fol. 1905] and naturally means heating prior to the time when softening is desired, i. e., prior to the depositing of the spot. If the preventive heat is to be applied to the crown unit when and only when the spot has been deposited, it is

not a prior heating and the prefix "pre" becomes meaningless, in view of the context.

2. I am unable now to recall why I used the precise wording and terminology I did use in drafting the specification in question. But I feel sure that had I intended to limit the step of effecting preventive heating to a time when and only when the spot had been deposited, I would naturally have said that the "assembled unit is heated as soon as the spot is deposited so as to soften the coating," or words to that effect, and would not have used the word "preheating" because in view of the context, "preheating" is illogical and more or less meaningless unless the heating is prior to the depositing of the spot.

3. As is more fully set forth in an affidavit of said Warth about to be filed herewith, the term "assembled crown" in the trade means definitely a metal shell in which has been inserted and affixed a cork disc or cushion. Therefore, when the sentence in question refers to preheating the "assembled crown," it logically means heating the metal shell and assembled cork disc and not that plus something else.

4. I am informed that some question has arisen over the comma appearing after the word "coating" in the above quoted sentence. I do not now recollect why or how that comma was inserted. But in my opinion, the presence or [fol. 1906] absence of that comma is immaterial because, in view of the above remarks the sentence should be construed to mean a heating prior to depositing the spot, comma or no comma. Certainly the comma was not inserted for the purpose of defining the preventive heating as being effected when and only when the spot has been deposited, i. e., it was certainly not inserted to make the words "as soon as" relate to the heating rather than to the softening. If its presence leads to such an interpretation, then and to that extent it is a typographical error.

I have read the proposed affidavits of Albin H. Warth and Frank L. Lloyd about to be filed herewith and the same are true to the best of my knowledge and belief.

Further deponent saith not. H. Monroe Humason.

Subscribed and sworn to before me this 9th day of March, 1934. John M. Crane, Notary Public. (Seal.)

1907

N° 16,075 A.D. 1913

Date of Application, 12th July, 1913—Accepted, 9th July, 1914

COMPLETE SPECIFICATION.

Improvements relating to Closures for Bottles, Jars and the like.

I, Ernest Frédéric Eduard Demuth, of Townmead Road, Fulham, London, in the County of Middlesex, Manufacturer, do hereby declare the nature of this invention and in what manner the same is to be performed, to be particularly described and ascertained in and by the following statement:—

My invention has reference to closures or stoppers for bottles jars and like vessels of the well known "crown cork" type.

In bottle closures of this kind the metallic shell or capsule is lined with a disc of resilient material usually cork which has sometimes been faced with tinfoil and which when the closure is applied to the mouth of the vessel serves to make a more or less tight joint and prevent the contents of the bottle leaking or in the case of aerated liquids preventing escape of gas. In practice however considerable difficulty is experienced in obtaining a satisfactorily tight joint more especially in the case of bottles containing aerated liquids for the reason that the cork lining which is necessarily thin and more or less permeable allows the liquid to pass through to the back thereof and so destroy the tightness of the joint, as it is not feasible to obtain as tight a joint between the glass bottle mouth and the metallic foil as is possible where the glass is directly in contact with the cork.

Now the object I have in view is to remedy the aforementioned defects and in order that my invention may be readily understood and carried into effect I will now proceed to describe the same fully for which purpose reference is to be had to the accompanying drawings in which:—

Figure 1 represents a bottom plan view of a closure of the "crown cork" type and

Figure 2 is a section taken on line *a—a* of Figure 1.

The metallic capsule 1 is as usual provided with a disc of cork or other resilient material 2 and this latter is in accordance with my invention provided a disc 3 of metallic foil parchment or similar thin liquid resisting material of such size that it shall prevent the liquid contents of the bottle coming into contact with the disc 2 while leaving sufficient of said disc 2 exposed that the mouth of the bottle may—when the closure is in position as indicated in Figure 2—make a tight joint directly therewith. The disc 3 is secured to the cork disc 2 by cementing or in any other appropriate manner.

A closure under the present invention effectually obviates the aforesaid disadvantages and that portion of the cork disc in direct contact with the bottle mouth is free to expand under climatic conditions without prejudicially affecting the tightness of the joint.

The disc 3 may be of any desired thickness without interfering in any way with the efficiency of the device.

Having now particularly described and ascertained the nature of my said invention and in what manner the same is to be performed, I declare that what I claim is:—

1. A closure of the crown cork type characterized by the fact that the cork or

[Price 8d.]

1629

1908

Demuth's Improvements relating to Closures for Bottles, Jars and the like.

like resilient lining is provided with a disc of metallic foil or like thin liquid resisting material in such a manner as to prevent the liquid contents of the bottle coming into contact with said cork lining while allowing the bottle mouth to abut directly against said lining substantially as described.

2. A closure of the crown cork type comprising the combination with a metallic shell or capsule a cork or like resilient lining arranged therein and a disc of protective material attached to said lining all arranged and operating as described for the purpose specified.

Dated this 11th day of July, 1913.

PROVISIONAL SPECIFICATION.

Improvements in and connected with Bottle Seals.

We, JOHN MACCORMACK, of Balcregan, Prestwick, Ayrshire, Scotland, Wire Manufacturer, and DAVID EGLIN MCPHUN, of Myrtle Cottage, Shettleston, Lanarkshire, Scotland, Secretary, do hereby declare the nature of this invention to be as follows:—

This invention relates to improvements in bottle seals.

In metallic seals, as presently in use, within the cap of such seals, there is a resilient washer of soft rubber and a lining of block tin, but seals made in such manner are not satisfactory inasmuch as the rubber rings never being of an equal size a perfect seal cannot be relied upon. The object therefore of our invention is to construct a seal which will be a perfect fit as well as to reduce the cost of manufacture.

According to our invention, we use in combination with the cap of the seal a disc of wood pulp or other similar material having a covering of tin foil. In manufacture the wood pulp is coated with an adhesive substance and then the tin foil is laid on and afterwards the discs stamped out.

Dated this 11th day of November, 1909.

JOHN LIDDLE,

Chartered Patent Agent.

COMPLETE SPECIFICATION.

Improvements in and connected with Bottle Seals.

We, JOHN MACCORMACK, of Balcregan, Prestwick, Ayrshire, Scotland, Wire Manufacturer, and DAVID EGLIN MCPHUN, of Myrtle Cottage, Shettleston, Lanarkshire, Scotland, Secretary, do hereby declare the nature of this invention and in what manner the same is to be performed, to be particularly described and ascertained in and by the following statement:—

This invention relates to improvements in that class of metallic bottle seals in which a disc or washer is placed within the cap of such seals, and has for its object to construct a seal which will be a perfect fit as well as reduce the cost of manufacture.

According to our invention, we use in combination with the ordinary cap of the seal a disc or washer of wood pulp, which is absorbent and expanding with moisture and with a layer of tin-foil intimately adhering to the underside of the disc or washer by an adhesive substance. In manufacture the wood pulp is coated with the adhesive substance and then the tin-foil is laid on and afterwards the discs or washers stamped out.

[Price 8d.]

1632

1911

Macnamara and McPhail's Improvements in and connected with Bottle Seals.

In order that our invention may be properly understood and readily carried into effect, we have hereunto appended one sheet of drawings, of which

Figure 1 is a section of part of the neck of a bottle sealed in combination with a disc or washer of wood pulp made in accordance with and embodying our invention.

Figure 2 is a plan of the disc or washer detached, and

Figure 3 is a side elevation of the same all hereafter more fully referred to and described.

Referring to the drawings, A is the disc or washer of wood pulp, which is coated on its under-surface with some adhesive material in order that a layer of tin-foil B, covering the under-surface shall be intimately attached thereto. In the sealing operation, the disc or washer A being composed of wood pulp which is absorbent and expanding with moisture; should any leakage take place, the moisture will act on the edge of the disc or washer and cause it to swell and so stop the leakage and thus make the seal a perfect fit.

Having now particularly described and ascertained the nature of our said invention and in what manner the same is to be performed, we declare that we are aware that it has been proposed to use in conjunction with bottle seals discs saturated in melted wax and with a loose sheet of tin-foil either above or below same and we make no specific claim for such but what we do claim is:—

In metallic bottle seals of the class in which a disc or washer is placed within the cap of such seals, forming such disc or washer of wood pulp coating same on its under side with an adhesive substance and intimately fixing thereto a layer of tin-foil all substantially as and for the purposes hereinbefore described and illustrated on the accompanying sheet of drawings.

Dated this 7th day of January, 1910.

UNITED STATES PATENT OFFICE.

JOHN A. JONES, OF NEW YORK, N. Y.

COMPOSITION CORK.

No. 903,865. Specification of Letters Patent. Patented Nov. 17, 1908.

Application filed June 12, 1907. Serial No. 378,589.

To all whom it may concern:

Be it known that I, JOHN A. JONES, a citizen of the United States, and a resident of New York, in the county of New York and State of New York, have invented a certain new and useful Composition Cork of which the following is a specification.

This invention relates to composition cork.

The main object of the invention is to provide a composition cork which can be used for all purposes for which corks, whatever the form thereof, made from cork wood, may be employed.

A particular object of the invention is to provide a composition cork capable of such use which will withstand a considerable amount of heat and pressure, as for example the heat of pasteurization employed in pasteurizing beer and similar liquids, and the pressures usually found in bottles containing carbonated beverages.

The process of producing composition cork of this character comprises essentially the mixing of suitably granulated cork with a binder such as a solution of pure rubber, and afterward compressing the granulated cork and heating it to a sufficient temperature while in the compressed condition to retain it substantially in the form to which it was compressed, that is to say, the heating should be carried far enough to vulcanize the rubber employed to unite the granules of cork.

The apparatus which may be employed for producing the composition cork may be varied considerably, but simple means for performing the essential operations will be hereinafter described in detail.

In the drawings Figure 1 is a sectional elevation of devices for forming granulated cork, which has been mixed with a suitable binder, into rods of composition cork. Fig. 2 is a sectional side elevation illustrating means for compressing such a cork rod in a tube. Fig. 3 is a similar view of a tube with a cork rod held therein under compression. Figs. 4 and 5 are details illustrating in end and side elevation respectively a finished cork rod, and means for cutting the same up into cork disks.

In carrying my invention into effect I may form the composition cork into solid pieces of any desired shape and size by utilizing a suitable mold in which to form the same. In order, however, to form cork rods, and cork disks from such rods, I prefer to make use of a cylinder or tube of considerable strength, which may be filled with granulated cork which has been mixed with a binder and into which the granulated material may be forced into a compact mass. Usually this cork will be filled into such a tube or cylinder, which is here indicated by 2, by tamping it in with a plunger such as 3, the granulated cork being preferably led to the receiving end of the tube 2 by means of a hopper or funnel, such as 4, the outlet from which is substantially of the same diameter as the receiving end of the cylinder 2 and registers therewith. By means of the plunger 3 the granulated cork in the hopper or funnel 4 is forced into the cylinder 2 and tamped down by repeated blows until the cylinder is filled with cork in a state of considerable compression.

As soon as the cylinder has been filled with approximately all the granulated cork that can be forced into it by this mode of filling and compressing the granulated material, additional pressure may be brought to bear by means of a pair of plungers, such as 5 and 6, fitting the opposite ends of the cylinder 2. These two plungers may be operated by power in any suitable manner, as by the reciprocating compressors 7 and 8 which force in the plungers 5 and 6 to the positions shown in Fig. 3, in which they may be held by pins, such as 9 and 10, passing through suitable openings, such as 11 and 12, in the tube 2 and through corresponding openings in the plungers 5 and 6. These plungers 5 and 6 thus constitute plugs for closing the ends of the cylinders 2 after the cork has been fully compressed therein. It will be noticed that the cork in the cylinder in Fig. 1 is compressed to approximately one-third its original length by the plungers or plugs 5 and 6, although the compression may be carried to any desired point within limits.

The material which is placed in the hopper 4 and compressed into the cylinder 2 is chiefly granulated cork. The cork should be granulated to such an extent that the major portion thereof will go through a screen of about three-sixteenths inch mesh, but the finer particles of cork and the cork dust may all be left in the mass and utilized. After granulation there is added to the cork a binder which is preferably a solution of pure rubber containing, or to which has been added a vulcanizing medium. In this solution sulfur, and gasolene or any other suit-

able volatile solvent of rubber may be employed. The proportions in which the different ingredients may be mixed will vary according to the character of the article to be made. For cork rods such as are shown in the drawings two ounces of granulated cork by weight and approximately one and one-half ounces by measure of rubber solution may be combined and thoroughly mixed so that every particle of the cork is covered with a thin film of vulcanizable binder. In the solution so combined with the cork I obtain good results by combining approximately one ounce of rubber by weight with a pint of gasolene, benzin or naphtha or other rubber solvent by measure, this solution containing a sufficient quantity of sulfur to assure vulcanization in the granulated mass after it is properly heated.

In preparing the materials for heating, the cork and the rubber solution are first thoroughly mixed so that every particle of cork is covered with a thin film of the vulcanizable liquid. The volatile portions of the solution are driven off in any suitable way, either by permitting the material to stand and the volatile substances to escape, or by subjecting the material to a temperature of about 70° F. to volatilize the solvent quickly. It is not essential to drive off the volatile substances at this stage of the process, though it is advisable to do so.

The granulated cork, after thoroughly mixing it with the solution just described, is then packed into cylinders, such as 2, or any other form of mold, as in the manner before described, that is, by tamping or otherwise filling the granulated material into tubes or cylinders, as shown and described in connection with Fig. 1. This tamping produces a substantially even and uniform rod throughout the length thereof, and this uniformity of compression is assured by subsequently forcing in the plungers or plugs 5 and 6 from both ends of the tube, the cork rod being compressed to substantially the same extent throughout its length by these various operations and devices. After compression the molded composition cork is subjected to the action of heat for the purpose of effecting vulcanization of the relatively small quantity of rubber contained in the compressed material. The temperature employed may be that of soft vulcanization and may vary from 125° to 350° F. Usually the desired temperature is maintained for from twenty to thirty-five minutes. The heat is ordinarily applied directly to the metallic tubes 2 while the mass of compressed material is held therein under compression, as by means of the plugs 5 and 6. After the tubes so heated have been cooled the plugs may be withdrawn therefrom and the rods removed. The rods resulting from these operations are compact and close-grained with no holes in them. The cork rods so formed may be cut up into pieces of any desired lengths, this being dependent upon the use to which such cut pieces are to be put. In Figs. 4 and 5 I have illustrated at 13 and 14 a cutter and its shaft for severing the cork rod into sections. Here this cork rod, which is designated by 15, is cut into short lengths to form cork disks, such as 16, each of these disks being only one-eighth inch or less in thickness, firm and close-grained, with no holes of any kind in them and having the particles of cork so intimately united that they will withstand all temperatures employed in pasteurizing beer, etc., and all pressures to which bottles containing carbonated liquids are subjected.

An important advantage resulting from the use of corks or cork disks made in the manner herein described is that they have great elasticity in the direction of the line of compression, that is to say, in the direction of the thickness of the cork disks, and this is a very important factor in sealing disks to be used in beer bottles and for analogous purposes.

What I claim is:

1. Composition cork, constituting a substantially homogeneous body of solid cork consisting of granules of pure cork covered with thin coatings of a binder which unites all the granules and is insoluble by, and substantially neutral in the presence of, water, beer, and similar beverages both at normal and at high temperatures and pressures.

2. Composition cork, constituting a substantially homogeneous body of solid cork consisting of granules of pure cork covered with thin coatings of rubber which is permanently united with all the granules by soft vulcanization and is insoluble by, and substantially neutral in the presence of, water, beer and similar beverages both at normal and at high temperatures and pressures.

3. A solid homogeneous elastic composition cork disk, consisting of granules of cork covered with thin coatings of rubber which is permanently united with all the granules by soft vulcanization and is insoluble by, and substantially neutral in the presence of, water, beer and similar beverages both at normal and at high temperatures and pressures.

4. A solid homogeneous elastic composition cork disk, consisting of granules of cork covered with thin coatings of rubber which is permanently united with all the granules by soft vulcanization while the cork and the rubber are in a compressed state, said rubber and the disk being insoluble by, and substantially neutral in the presence of, water, beer and similar beverages both at normal and at high temperatures and pressures.

5. Composition cork, constituting a sub-

stantially homogeneous body of solid cork having its air cells substantially unclogged and of substantially the same resiliency as natural cork wood and consisting of granules of pure cork covered with thin coatings of a binder which unites all the granules but does not impregnate them and which is insoluble by, and substantially neutral in the presence of, water, beer and similar beverages both at normal and at high temperatures and pressures.

6. Composition cork embodying a substantially homogeneous body of solid cork incapable of shrinkage under any ordinary conditions of atmosphere or use as a sealing medium and consisting of granules of pure cork covered with thin coatings of a binder which unites all the granules and is insoluble by water, beer and similar beverages both at normal and at high temperatures and pressures.

7. Composition cork constituting a substantially homogeneous body of solid cork normally expansible and incapable of shrinkmosphere or use as a sealing medium and age under any ordinary conditions of atmosphere or use as a sealing medium and consisting of granules of cork covered with thin coatings of a binder which unites all the granules and is insoluble by, and substantially neutral in the presence of, water, beer and similar beverages both at normal and at high temperatures and pressures.

Signed at New York, in the county of New York, and State of New York, this 11th day of June, A. D. 1907.

Correction in Letters Patent No. 903,865.

It is hereby certified that in Letters Patent No. 903,865, granted November 17, 1908, upon the application of John A. Jones, of New York, N. Y., for an improvement in "Composition Cork," an error appears in the printed specification requiring correction, as follows: Page 3, line 25, consisting of the words "mosphere or use as a sealing medium and" should be stricken out; and that the said Letters Patent should be read with this correction therein that the same may conform to the record of the case in the Patent Office.

Signed and sealed this 22d day of December, A. D., 1908.

UNITED STATES PATENT OFFICE.

JOHN A. JONES, OF NEW YORK, N. Y.

VESSEL-SEAL.

1,110,138. Specification of Letters Patent. Patented Sept. 8, 1914.

Application filed October 16, 1909. Serial No. 522,941.

To all whom it may concern:

Be it known that I, JOHN A. JONES, a citizen of the United States, and a resident of New York, in the county of New York and State of New York, have invented certain new and useful Improvements in Vessel-Seals, of which the following is a specification.

This invention relates to vessel seals, and particularly to a vessel seal formed as a unitary article, which invention is disclosed in Letters Patent of Mexico, dated October 27th, 1908 and numbered 8,516; France, #395,950, dated November 4th, 1908; Spain, #44,304, dated January 16th, 1909; and Belgium, #211,762, dated November 6th, 1908.

The main object of the invention is to provide a device of this description having a metal or equivalent stiff cap adapted to engage the neck of a bottle or similar article and a sealing layer formed therein. This sealing layer may be of any material suitable for the purpose, either a single substance or a combination of two or more substances, and said substance or combination should be sufficiently plastic to permit its being formed or molded within said cap. When the sealing layer is composed of small particles of material united by a binder, as will usually be the case, the composition will be fed into the caps, formed or molded therein, subjected to pressure, and the binder set while the composition is under compression. Said composition is generally made up of particles of granules of cork coated with a binder. This composition is fed into metal shells, held under compression to form a sealing layer or disk, and the binder then set, in which case the sealing layer formed in said cap is a substantially homogeneous but soft, elastic and readily compressible body of solid gas-tight cork made up of granules permanently united by thin coatings of a binder that is substantially neutral in the presence of water, beer and similar beverages under all ordinary conditions of bottling, pasteurization and use, and capable of withstanding the temperature of pasteurization without being dissolved, disintegrated or distorted thereby, and substantially incapable of shrinkage under any ordinary conditions of temperature or use.

Bottle seals of the crown type as previously made have consisted of a metal cap adapted to engage a bottle neck and a sealing disk of cork wood inserted therein and insecurely held by friction or an adhesive. Cork disks, however, even of the best quality, are more or less porous, causing leakage of gas when used on bottles containing beer or aerated liquids. The porous nature of cork disks also necessitates the use of a layer of waxed paper or similar material between the cap and the cork to prevent corrosion of the metal. Such seals are also unduly expensive, it being necessary to use the best grades of cork wood to insure good results. Moreover, many operators, both hand and machine, have been necessary in cutting and sorting these disks, treating them to increase their pliability, cutting paper fillers therefor, and assembling these various independent parts in the metal shell, the result being an expensive closure. To increase the effectiveness of vessel seals and at the same time decrease the cost of production thereof, applicant has produced an article having a non-porous sealing layer formed or molded directly in the metal cap and preferably adhering thereto. This sealing layer may be of any material capable of sealing a bottle mouth, a preferred type being that in which granules of cork are united by a binder, said sealing layer being in such case non-porous, elastic, and capable of withstanding a considerable amount of heat and pressure, such as the heat of pasteurization and the pressure usually found in bottles containing carbonated beverages, and the binder being insoluble by and substantially neutral in the presence of water, beer or similar beverages.

In the drawings Figure 1 is an underside view of a vessel seal embodying my invention, and Fig. 2 is a section of the same.

In the drawings I have shown a unitary vessel seal, designated generally by 1, said seal consisting of an outer shell or cap 2 of any suitable form, and usually of metal, adapted to engage the neck of a bottle, and a molded or formed sealing layer 3 therein of any material suitable for sealing the mouth of a bottle or similar vessel. Good results have been obtained by the use for this purpose of a composition of granulated cork and a binder, and said binder may be any suitable for the purpose. The ingredients of this composition may be combined in varying proportions and under different

conditions to produce a sealing layer of sufficient elasticity to insure an effective closure for such vessel mouth. When the sealing layer is a composition of an adhesive nature, as will usually be the case, it is particularly favorable to the formation of a unitary seal, said composition being formed or molded directly in the cap and adhering thereto without the interposition of any additional member such as the paper necessary with porous cork disks.

A unitary seal as herein described possesses many advantages over the ordinary closure or any seal having the cap and the sealing layer made as separate articles requiring assembling. It is more effective, owing to the non-porous character of the formed sealing layer, and also because of the certainty that said sealing layer will be positively held in the cap, which is not the case with the loose or slightly cemented-in cork disk. The cost of production is also much less than in the case of articles heretofore used, as the sealing layer is ordinarily made of materials that are easily obtained and cheap, this being especially the case when granulated cork is employed. The binder, of which a very small amount is ordinarily employed, is also inexpensive. Another great saving arises out of the reduction of the number of operations necessary to produce the finished product.

No one has made, so far as I am aware, a complete vessel seal, consisting of a metal cap and a layer of sealing material—preferably composition cork such, for example, as described herein—formed in such cap; nor has any one made such a vessel seal with a sealing layer, whether of this or some other material, permanently united with the metal cap so that the seal, considered as a whole, is a unit and not a mere assemblage of independent elements; and these are important features of my invention.

A vessel seal such as herein described may be used for all purposes for which seals of large or small diameter have heretofore been employed, and on bottles containing beer, aerated liquids and other beverages, as well as on vessels containing liquids or commodities not containing gas pressure.

In forming my unitary seal, any metal or other stiff cap may be used that is adapted to engage a bottle neck. Within this cap is placed a portion of material capable of forming a seal for the mouth of a bottle and preferably adapted to adhere to the cap. Said sealing material is then formed in said cap as desired and subjected to further treatment, if necessary, to cause it to retain the desired form. When this sealing material is a composition of granulated cork and a binder of rubber the rubber is subjected to soft vulcanization while the sealing layer is held under compression. These operations may be carried out in the manner described in Patent #903,865, granted to me November 17th, 1908.

What I claim is:

1. A vessel seal, comprising a flanged metal cap having at its inner side a cavity constituting a mold space, and a molded layer of compressible and expansible solid sealing material formed under pressure in said cap and forced by said pressure into intimate union with the cap to form a unitary article.

2. A vessel seal, comprising a flanged metal cap having at its inner side a cavity constituting a mold space, and a molded layer of compressible and expansible solid composition sealing material formed under pressure in said cap and forced by said pressure into intimate union with the cap to form a unitary article.

3. A vessel seal, comprising a flanged metal cap having at its inner side a cavity constituting a mold space, and a molded layer of compressible and expansible solid composition cork formed under pressure in said cap and forced by said pressure into intimate union with the cap to form a unitary article.

4. A vessel seal, comprising a flanged metal cap having at its inner side a cavity constituting a mold space, and a layer of sealing composition molded in said cap under pressure and forced by said pressure into intimate union with the cap, said composition being a substantially homogeneous but soft elastic and readily compressible body of solid gas-tight cork made up of granules permanently united with one another and with the metal cap by thin coatings of a binder, said body being also substantially incapable of being dissolved, disintegrated or distorted by pasteurization.

5. A vessel seal, comprising a flanged metal cap having at its inner side a cavity constituting a mold space, and a layer of sealing composition molded in said cap under pressure and forced by said pressure into intimate union with the cap, said composition being a substantially homogeneous but soft elastic and readily compressible body of solid gas-tight cork made up of granules permanently united with one another and with the metal cap by thin coatings of a binder, said body being also substantially incapable of being dissolved, disintegrated or distorted by pasteurization and substantially incapable of shrinkage when in use.

6. A vessel seal, comprising a flanged metal cap having at its inner side a cavity constituting a mold space, and a disk of sealing composition molded in said cap under pressure and forced by said pressure into intimate union with the cap, said composition being a substantially homogeneous but

t elast' and readily compressible body solid gas-tight cork made up of granules rmanently united by means of soft vulnization by thin coatings of a rubber nder, said disk being also substantially inpable of being dissolved, disintegrated or torted by pasteurization and being subntially incapable of shrinkage when in use.

Signed at New York, in the county of New York, and State of New York, this 14th day of October, A. D. 1909.

UNITED STATES PATENT OFFICE.

GEORGE M. C. NIELSEN, OF MILLIS, MASSACHUSETTS, ASSIGNOR TO UNITED CORK & SEAL CO., OF MILLIS, MASSACHUSETTS, A CORPORATION OF MAINE.

MACHINE FOR MAKING BOTTLE-CAPS.

1,195,392. Specification of Letters Patent. Patented Aug. 22, 1916.

Application filed April 28, 1909. Serial No. 493,051.

To all whom it may concern:

Be it known that I, GEORGE M. C. NIELSEN, a citizen of the United States of America, and a resident of Millis, in the county of Norfolk and State of Massachusetts, have invented certain new and useful Improvements in Machines for Making Bottle-Caps, of which the following is a specification.

This invention relates to an apparatus for manufacturing bottle caps and particularly to that class of caps which are provided with a lining of cork secured to the inner side of the cap by means of an adhesive.

It has for its object the provision of means for assembling the various parts of the cap and when thus assembled, subjecting them to heat to cause the adhesive to adhere to the cork and the cap between which it is interposed and then subjecting the cap to pressure for a limited length of time and subjecting the cap to the action of a cold air blast while under pressure.

Another object of the invention is to provide a means for protecting the inner face of the cork lining from the action of the contents with which the bottles on which the caps are used are filled.

The invention consists in certain novel features of construction and arrangement of parts which will be readily understood by reference to the description of the drawings and to the claims hereinafter given.

Of the drawings: Figure 1 is a side elevation of one end of a machine embodying the features of this invention, portions thereof being cut in section on line 1—1 on Fig. 3. Fig. 2 is a rear elevation of the same. Fig. 3 is a horizontal section of the same, the cutting plane being on line 3—3 on Fig. 2. Fig. 4 is an enlarged vertical section of the devices for stamping out the protecting plates, the cutting plane being on line 4—4 on Figs. 1 and 3. Fig. 5 is a vertical section of the end of the machine opposite to that shown in Fig. 1. Fig. 6 is an enlarged transverse section of a portion of the same, the cutting plane being on line 6—6 on Fig. 5. Fig. 7 is a plan of a portion of the chain conveyer, showing a completed cap supported thereon. Fig. 8 is an enlarged vertical section showing the cutting dies for cutting out the cork protecting plates from strips of facing material. Fig. 9 is a plan of a blank cut from the sheet of facing material by the cutting die. Fig. 10 is an inverted plan of the protecting plate after an annular flange has been formed thereon. Fig. 11 is a vertical section similar to Fig. 8 showing the positions of the various parts assumed after the annular flange has been formed upon the protector plate. Fig. 12 is a sectional elevation, the cutting plane being on line 12—12 on Fig. 3 and showing the various devices for cutting the annular groove in the cork lining to the cap, placing the flanged protector plate thereon, and forcing the flange thereof into said annular groove. Fig. 13 is a section of a cap after the annular groove has been cut into the cork lining in which condition it is positioned beneath the plunger, adapted to force the protecting plate therein. Fig. 14 is an enlarged section showing the operation of the device for forcing the protecting plate into the annular groove in the cork lining, and Fig. 15 is a section of the completed seal with the protector plate therein.

Similar characters designate like parts throughout the several figures of the drawings.

In the drawings, 10 represents a bed mounted on any suitable supports such as the legs 11 and provided with the upwardly extending guide members 12 in the upper end of which is mounted a revoluble crank shaft 13, the outer end of which is preferably supported in a bracket 14 and has secured thereto a pulley 15 through which power is imparted by means of the belt 16 to said crank shaft 13. The cranks 17 formed upon or secured to the shaft 13 are connected by links 18 to a member 19 adapted to be vertically reciprocated on the guides 12 during the revolution of the shaft 13. The crank shaft 13 has also secured thereto a bevel gear 20 meshing with a similar bevel gear 21 secured to a vertical shaft 22 having at its upper end a bearing 23 in the bracket 14. Keyed to the lower

end of this shaft is a large gear 24 meshing with a smaller gear 25 supported upon a stud 26 secured to the under side of the bed 10. The hub of the gear 25 has formed thereon a crank arm 27, the outer end of which is provided with a roller adapted to engage with the radial slots 28 in a disk 29 revolubly mounted upon the lower end of the shaft 22 and thus cause an intermittent movement of a small gear 30 formed upon and movable with said disk plate 29. This smaller gear 30 meshes with a large gear 31 keyed to the shaft 32, shown in dotted lines in Fig. 3, the upper end of said shaft 32 having secured thereto so as to be revoluble therewith a large dial plate 33. The gear 31 also meshes with a smaller gear 34 secured upon the lower end of the shaft 35 mounted in a vertical bearing 36 secured to the side of the bed plate 10, the upper end of said shaft 35 having keyed thereto a smaller dial plate 37, the lower face of which coincides with the upper face of the dial plate 33.

The dial plate 33 rests upon a bolster plate 38 secured to the upper face of the bed 10, the upper face of the dial plate 33 being provided with a plurality of pockets 39, each one of which is adapted to receive a cup-shaped metal cap 40 such as is shown in Figs. 13 and 15. These cup-shaped members are fed into the pockets 39 at the front of the machine in any well-known manner either by any well-known automatic feeding device or they may be fed thereto by hand, if desired. Preferably these cup-shaped members are fed automatically to the pockets 39 at the point 41, as indicated in Fig. 3 of the drawings, and then by the rotation of the dial plate 33 they are carried by the intermittent movements of said dial plate to the position 42, indicated in Fig. 3, where each in its turn receives a circular disk of adhesive material cut from any suitable source of supply and placed in the bottom of the cup-shaped member by the downward movement of the plunger 43 secured to the under face of the reciprocating member 19. The further rotation of the dial plate carries the cup-shaped members successively to the position indicated at 44 on Fig. 3 where each cup-shaped member is supplied with a cork filling, these disks of cork being fed thereto in any well-known manner, either automatically or otherwise, as desired. The metal cup-shaped member, with the disk of adhesive material and the layer of cork therein is then moved with the dial 33 into a position beneath the bunter 45 which, in the downward movement of the reciprocating frame 19, forces the cork filling onto the adhesive material and insures a proper seating of the same within said cup-shaped member. A pilot pin 46 securely attached to the reciprocating frame 19 is adapted, in the downward movement of said frame 19 to enter one of the holes 47 of the dial plate 33 and thereby position the dial plate on the completion of each of its successive movements, thus insuring steadiness during the various operations and also acting as a lock to prevent further movement of said dial plate until the operations in progress are completed. When the cap has passed from beneath the bunter 45 it is in condition to receive the metal facing or protector plate which constitutes one of the most important features of this invention. In order to provide for this a grooved cutter 46 is adjustably secured to the reciprocating frame 19 and in its downward movement the cutting edge thereon cuts into the layer of cork 47 within the metal cup-shaped member 40 an annular groove 48, when said cup-shaped member 40 is in the position 49 indicated in Fig. 3 of the drawings. The next movement of the dial 33 carries the cup-shaped member 40 with its disk of adhesive material 50 and its lining of cork 47 having the annular groove 48 cut in its upper face into the position 51 beneath an open ended pocket 52 in the small dial 37, the pocket 52 and the pocket 39 being in axial alinement and also in axial alinement with a plunger 53 secured to the under face of the reciprocating member 19. This plunger 53 has slidably mounted thereon a sleeve 54 provided with slots 55 into which project the ends of a pin 56 passing through said plunger 53 to limit the movement of said sleeve in either direction, said sleeve being normally retained in the position shown in Fig. 12 of the drawings by means of a spiral spring 57 surrounding said plunger 53. When the cup-shaped member 40 is thus positioned at 51 beneath the pocket 52, the pocket 52 contains a metal protector plate 58 provided with an annular flange 59 which extends downwardly in said pocket 52 in position to be forced by the downward movement of the plunger 53 into the annular groove 48 formed in the cork disk 47 in the cup-shaped member 40, thus leaving the cup-shaped member provided with the protector plate 58, as shown in Fig. 15 of the drawings, this protector plate, when the caps are in use, being adapted to cover the opening of the mouth of the bottle to which the cap or seal is secured to prevent the contents of the bottle from acting upon the cork lining to cause its deterioration and consequential disintegration which permits small particles of cork to drop into the contents of the bottle to its manifest injury. During this operation the pilot pin 60 secured to the reciprocating member 19 enters one of the holes 61 in the small dial 37 and accurately registers the dial during the operation of the plunger 53, the sleeve 54 being retracted against the tension of the spring 57 during the opera-

tion of the plunger. The next movement of the dial 33 brings the cup-shaped member 40 to the position 63 indicated in Fig. 3 of the drawing in which position the downward movement of the plunger 64 secured to the reciprocating member 19 acts upon the protector plate 58 to slightly cup the same, as indicated in Fig. 15 of the drawings.

The bottoms of each of the pockets 39 of the dial plate 33 are formed by the plungers 65 traveling in an annular groove 66 in the bolster plate 38. In the bottom of the groove 66 is secured a cam member 67 slightly in advance of the position 63, indicated in Fig. 3 of the drawings, so that as the disk 33 continues to rotate after the metal protector plate 58 has been subjected to the action of the bunter 64 the cam 67 will act upon these plungers 65 to elevate them and force the cup-shaped members 40 out of the pockets 39 in the dial plate 33. While the plungers 65 are in such elevated position upon the cam 67 and supporting the cup-shaped members 40 these members 40 come into contact with a deflector plate 68 which causes the cup-shaped members to be dropped into an inclined chute 69, the opposite end of which delivers the cup-shaped members to a continuous chain carrier 70, each link of which is provided with a central opening and is constructed to receive one of the cup-shaped members 40. The plungers 65 are returned to their seats by means of a bunter pin 45* similar to 45 which insures a proper pocket being ready to receive the cups at the feeding point 41. The chain 70 is supported by a tray 71 having side flanges or guides, said tray being provided with two long slots or perforations 71ª and 71ᵇ extending through the bottom thereof. Beneath one of the perforations 71ª in the bottom of the tray 71 is a slotted gas pipe 72 to which gas is supplied through the pipe 73 from any suitable source. When the gas passing from the slots or jets in the pipe 72 is ignited and the flames therefrom come into contact with the outer face of the cup-shaped member 40 supported by the perforated chain carrier 70, the heat from said gas flames will act upon the adhesive material contained within the cup-shaped members 40 and soften the same, making it more tacky. Immediately above the chain 70 is another endless chain 74 provided with a plurality of pressure members 75 adapted to enter the cup-shaped member 40 and force the cork disk 47 and disk of adhesive 50 into closer contact with each other and the inner end of the member 40. After the members 40 have been subjected to the heat from the gas jets of the pipe 72 the chain 74 comes into contact with a pressure plate 76 located over the second slot or perforation 71ᵇ in the tray 71 and adjustable toward and from the chain 70 and its track or tray 71 by means of the adjusting screws 77 in the frames 78. By means of these adjusting screws 77 the position of the pressure plate may be regulated relative to the track or tray 71 and beneath this second slot is a pipe 79 provided at its top with a plurality of slots through which cold air may pass or be forced from any suitable source of supply communicating with said pipe 79 by the pipe 80 to set the adhesive while under pressure. It is obvious therefore that as the members 40 pass over the gas flames the adhesive material is subjected to the heat therefrom and becomes tacky and when in this tacky condition the continued movement of the carriers 70 and 74 causes the pressure members 75, contacting with the protector plate 58 to be pressed downwardly to insure the firm adherence of the cork to the cap through the instrumentalities of the disk of adhesive material, and while pressure is being thus subjected to the contents of the cup-shaped member 40, the exterior of the cup-shaped member is being subjected to a blast of cold air to cool the same and insure the adherence of the various members of the seal. As the chain 70 passes over the sprocket wheel 81, the finished caps fall off into any suitable receptacle. The sprocket wheel 81 is revolubly mounted upon a shaft 82 mounted in any suitable bearing in a framework 83, the opposite end of the chain 70 being mounted upon a similar sprocket wheel 84 on a shaft 85 driven by means of a pulley 96 which is secured thereon. A gear 86 secured to the shaft 85 meshes with a similar gear 87 on the shaft 88 and on this shaft 88 is a sprocket wheel 89 connected by means of a sprocket chain 90 to a sprocket wheel 91 on a shaft 92 mounted in the framework 83. This shaft 92 has also mounted thereon a sprocket wheel wheel 93 driving the endless chain 74, the opposite end of which is mounted upon the sprocket wheel 94 on the shaft 95. It is obvious that by this construction of driving mechanism the chains 70 and 74 are driven in unison.

Secured to the bed 10 are suitable brackets 97—97* supporting an auxiliary table 98, one end of which is provided with suitable bearings 99 for a shaft 100 upon which is revolubly mounted a reel 101 containing a strip 102 of suitable facing material such as tin, which is adapted to travel along a groove in the upper face of the auxiliary table 98 which extends diametrically of the dial plate 37 and slightly above the same. This strip of material 102 is fed along said groove in the table 98 by means of a suitable feeding mechanism, to be hereinafter described, beneath suitable devices for punching out from the strip of material a flat disk and then by means of forming tools acting in conjunction with the aforesaid punch, upsetting the edges of the disk

to form an annular flange of the right diameter to fit the annular groove in the cork filling.

Secured to the upper face of the auxiliary table 98 is a bearing 103 in which is mounted a punch 104, the upper end of which is provided with an annular groove which is engaged by a forked member 105 secured by screws 106 to the reciprocating member 19. The lower end of the punch 104 is provided with a cylindrical chamber in which is mounted a plunger 107, the stem of which is provided with a pin 108 extending into a diametral slot 109 in said punch, this pin 108 co-acting with the ends of the slot 109 to limit the movement of the plunger 107 in either direction. A spring 110 in a suitable socket in the punch 104 normally retains the plunger in its lowermost position, as indicated in Fig. 4, with the pin 108 at the lower end of the slot 109. The auxiliary table 98 is provided with an opening therethrough in axial line with said punch 104 and has set therein an annular member 111 with a shearing edge, the interior diameter of which coincides with the exterior diameter of the punch 104. It is obvious, therefore, that as the strip of material 102 is fed along the groove in the upper face of the auxiliary table 98 over the annular member 111, that any downward movement of the reciprocating member 19 will cause the punch 104 to operate upon the strip of material and punch therefrom a circular disk or blank 112 suitable to form the protector plate 58. The spring 110 is only strong enough to force the plunger 107 downward after the cutting of the blank is completed, this plunger 107 in its downward movement resting upon the strip of material until the punch 104 has performed its function in cutting the blank 112 from said strip. In axial line with said plunger 107 is an auxiliary plunger 113 sliding in the bracket 97*, this plunger 113 being forced upwardly by means of a lever 114 pivoted at 115 to a bracket 116 secured to the lower side of the bed 10. A rod 117, pivoted to the opposite end of said lever 114 and having a bearing in an ear 118 formed upon the bed 10, is normally held in raised position by means of a spring 119 interposed between said ear 118 and a collar 120 secured to said rod 117.

The upper end of the rod 117 extends into a socket 121 secured to a rod 122 attached to the under side of the reciprocating member 19. The normal positions of the punch 104 and plungers 107 and 113 are as indicated in Fig. 4 of the drawings. When, however, the reciprocating member 19 moves downwardly the forked member 105 on this member acts upon the punch 104 and moves it downwardly into contact with the strip of material 102 and continuing its downward movement the punch coöperating with the shearing edge of the annular member 111 cuts from the strip of material a blank 112 which is forced downwardly in advance of the punch 104 and the spring-pressed plunger 107 therein until the end of the punch has nearly reached the end of its downward movement. At this time the downward movement of the rod 122 will cause the lower end of the socket 121 to come into contact with the upper end of the rod 117 and cause the lever 114 to operate so that the plunger 113 will be raised and come into contact with the blank 112 and force this blank against the plunger 107 causing the spring 110 to be compressed, this operation causing the flange 59 to be formed upon the blank 112, as indicated in Figs. 8, 10, and 11 of the drawings. As the member 19 moves upwardly the auxiliary plunger 113 will be moved downwardly as indicated in Fig. 11 and the punch 104 will be moved upwardly as indicated in the same figure. The spring 110, however, will have sufficient tension to cause the plunger 107 to move downwardly at this time following the movement of the plunger 113 until the pin 108 reaches the lower end of the slot 109, when further downward movement of the plunger 107 and the protector plate 58 will cease while the auxiliary plunger 113 continuing its downward movement will separate itself from the protector plate 58 and return to its normal position. A continuation of the upward movement of the punch 104 will act upon the pin 108 to raise the plunger 107 and return both the punch 104 and the plunger 107 to their normal positions leaving the protector plate 58 within the cylindrical chamber of one of the annular members 123, one of which is located in each of a plurality of cylindrical openings in the dial plate 37. Each of the members 123 is provided with an outwardly extending flange 124 which by a spring 125 is forced into engagement with a retaining ring 126 set into the upper face of the dial plate 37. The lower face of the member 123 is provided with an annular wedge-shaped lip 127, the diameter of which coincides with the diameter of the cutting edge of the groove cutter 46. When the punch 104 and plungers 107 and 113 have returned to their normal positions and the protector plate 58 has been formed and left within the member 123, a rotation of the dial plate 37 will bring the member 58 into the position 51 indicated on Fig. 3 of the drawings, beneath the plunger 53. The downward movement of the member 19 carries with it by means of the spring 57 the sleeve 54 which comes into contact with the upper end of the annular member 123 and owing to the greater tension of the spring 57 over that of the spring 125 the member 123 is forced downwardly so that the wedge-shaped annular lip 127

thereon will enter the annular groove 48 in the cork lining 47 and open up this groove 48 for the admission of the flange 59 of said cup-shaped protector plate 58, the plunger 53 coming into contact with the outer face of this member 58 and forcing it into the groove 48 as soon as it has been opened up by the wedge-shaped annular lip 127. The upward movement of the member 19 returns the plunger 53 and the spring-pressed members 54 and 123 to their normal positions and when this has been accomplished the cup-shaped member 40 with its cork lining and protector plate therein is free to be moved in its pocket in the dial 33 into other positions and finally delivered from said dial onto the endless chains where it is subjected to heat pressure and then a cooling blast, as has been previously described.

A strip 102 is fed from the reel 101 along the groove in the upper face of the auxiliary table 98 by means of a feeding mechanism of any well-known pinch-feed type. The reciprocating movement is given to the feeding mechanism by means of a bell crank lever 128 pivoted at 129, one arm of which is forked and supports the trunnions 130 of the upper jaw 131 of the feeding mechanism while the other arm has pivotally connected thereto a rod 132 having a bearing in an ear 133 secured to the under side of the reciprocating member 19. Beneath the ear 133 is a collar 134 secured to said rod 132, while said rod is also provided with another collar 135 above said ear between which and said collar is interposed a spring 136, which, by its tension, keeps the rod 132 in a raised position until in the downward movement of the reciprocating member 19, the ear 133 comes into contact with the collar 134 and moves the bell crank lever 128 about its pivot 129 until it engages with the shoulder 137, which forms a stop to limit the movement of the bell crank lever in that direction. On the upward movement of the member 19 the spring 136 will act upon the collar 135 to move the bell crank lever in the opposite direction until it engages the stop 138, these stops 137—138 limiting the movement of feed of the strip 102 during any single reciprocation of the member 19. During the movement of the bell crank lever 128 about its pivot toward the stop 137 the jaw 131 will be opened by the action of the ear 139 pivotally mounted upon the reciprocating member 19 coming into contact with the spring 140 resting upon the collar 141 secured to a rod 142 pivotally secured to the rearwardly extending arm of the jaw 131, said rod 142 passing through an ear 139 and being provided with a collar 143 above said ear 139 between which and said collar is interposed a second spring 144. It is obvious that the spring 144 normally retains the jaw 131 in contact with the strip of material 102 and pinches the same between it and the fixed jaw during the forward movement of the lever 128, thus positively feeding the strip of material 102 the required distance along the groove in the auxiliary plate.

This provides a very effective apparatus whereby the various elements forming the cap may be assembled together and fixedly secured in position while a protector plate is formed during the same operation and fixed to the lining to the bottle cap in such position that when in use the cork lining to the cap will not be exposed to the action of the contents of the bottle to which the cap is secured.

It is believed that the operation and many advantages of the invention will be thoroughly understood from the foregoing.

Having thus described my invention, I claim:

1. In an apparatus of the class described, the combination of a support provided with a pocket adapted to receive a flanged bottle cap containing a layer of cork; means for forcing into the face of said layer of cork a metal plate, the outer edge of which is removed from the inner wall of said flange; and mechanism for moving said support and forcing means relative to each other and positioning them in axial alinement during the insertion of said metal plate.

2. In an apparatus of the class described, the combination of a support provided with a pocket adapted to receive a flanged bottle cap containing a layer of cork; means for forcing into the face of said layer of cork a flanged metal plate, the outer wall of which is separated from the inner wall of the flange on said cap; and mechanism for moving said support and forcing means relative to each other and positioning them in axial alinement during the insertion of said metal plate.

3. In an apparatus of the class described, the combination of a support provided with a pocket adapted to receive a flanged bottle cap containing a layer of cork; means for forcing into the center of the face of said layer of cork a metal plate of less diameter than said cap, the outer edge of which is separated from the flange of said cap; and mechanism for moving said support and forcing means relative to each other and positioning them in axial alinement during the insertion of said metal plate.

4. In an apparatus of the class described, the combination of a support provided with a pocket adapted to receive a bottle cap containing a layer of cork; means for forming a circular flanged metal plate; means for positioning said plate with its center centrally disposed relative to said bottle cap and means for forcing the flange of said plate into said cork.

5. In an apparatus of the class described, the combination of a movable support provided with a pocket adapted to receive a bottle cap containing a layer of cork; mechanism for forming a flange upon a circular metal plate; means for positioning said cap beneath said flanged plate with their centers opposite each other; and means for forcing said flange into said cork.

6. In an apparatus of the class described, the combination of a support provided with a pocket adapted to receive a bottle cap containing a layer of cork; a reciprocating device for cutting an annular groove in said cork; mechanism for forming a flanged circular metal plate; and a device for forcing the flange of said plate into said groove.

7. In an apparatus of the class described, the combination of a movable support provided with a pocket adapted to receive a bottle cap containing a layer of cork; a reciprocating device for cutting an annular groove in said cork; mechanism for forming a flanged circular metal plate; a device for forcing the flange of said plate into said groove; and means for moving said support to successively position said cap beneath said groove-cutting device and then beneath said plate-forcing device.

8. In an apparatus of the class described, the combination of a movable support provided with a plurality of pockets each adapted to receive a bottle cap containing a layer of cork; a reciprocating device for cutting an annular groove in said cork; mechanism for forming a flanged circular metal plate; a device for forcing the flange of said plate into said groove; and means for moving said support to successively position said cap beneath said groove-cutting device and then beneath said plate forcing device.

9. In an apparatus of the class described, the combination of a movable support provided with a plurality of pockets each adapted to receive a bottle cap containing a disk of adhesive and a layer of cork; a reciprocating device for cutting an annular groove in said cork; mechanism for forming a flanged circular metal plate; a device for forcing the flange of said plate into said groove; and means for moving said support to successively position said cap beneath said groove-cutting device and then beneath said plate-forcing device.

10. In an apparatus of the class described, the combination of a movable support provided with a plurality of pockets each adapted to receive a bottle cap containing a disk of adhesive and a layer of cork; a reciprocating device for cutting an annular groove in said cork; mechanism for forming a flanged circular metal plate; a device for forcing the flange of said plate into said groove; means for moving said support to successively position said cap beenath said groove-cutting device and then beneath said plate-forcing device; and means for applying heat to said cap to cause said adhesive to adhere to said cork and the inner face of said cap.

11. In an apparatus of the class described, the combination of a movable support provided with a plurality of pockets each adapted to receive a bottle cap containing a disk of adhesive and a layer of cork; a reciprocating device for cutting an annular groove in said cork; mechanism for forming a flanged circular metal plate; a device for forcing the flange of said plate into said groove; means for moving said support to successively position said cap beneath said groove-cutting device and then beneath said plate-forcing device; and a series of gas jets for applying heat to said cap to cause said adhesive to adhere to said cork and the inner face of said cap.

12. In an apparatus of the class described, the combination of a movable support provided with a plurality of pockets each adapted to receive a bottle cap containing a disk of adhesive and a layer of cork; a reciprocating device for cutting an annular groove in said cork; mechanism for forming a flanged circular metal plate; a device for forcing the flange of said plate into said groove; means for moving said support to successively position said cap beneath said groove-cutting device and then beneath said plate-forcing device; a series of gas jets; and means for carrying said caps over said jets to permit the heat therefrom to act upon said adhesive.

13. In an apparatus of the class described, the combination of a movable support provided with a plurality of pockets each adapted to receive a bottle cap containing a disk of adhesive and a layer of cork; a reciprocating device for cutting an annular groove in said cork; mechanism for forming a flanged circular metal plate; a device for forcing the flange of said plate into said groove; means for moving said support to successively position said cap beneath said groove-cutting device and then beneath said plate-forcing device; means for applying heat to said cap to cause said adhesive to adhere to said cork and the inner face of said cap; and means for applying pressure to the cork while the adhesive is in a heated state.

14. In an apparatus of the class described, the combination of a movable support provided with a plurality of pockets each adapted to receive a bottle cap containing a disk of adhesive and a layer of cork; a reciprocating device for cutting an annular groove in said cork; mechanism for forming a flanged circular metal plate; a device for forcing the flange of said plate into said groove; means for moving said support to

successively position said cap beneath said groove-cutting device and then beneath said plate-forcing device; means for applying heat to said cap to cause said adhesive to adhere to said cork and the inner face of said cap; means for applying pressure to the cork while the adhesive is in a heated state; and means for cooling said cap.

15. In an apparatus of the class described, the combination of a movable support provided with a plurality of pockets each adapted to receive a bottle cap containing a disk of adhesive and a layer of cork; a reciprocating device for cutting an annular groove in said cork; mechanism for forming a flanged circular metal plate; a device for forcing the flange of said plate into said groove; means for moving said support to successively position said cap beneath said groove-cutting device and then beneath said plate-forcing device; means for applying heat to said cap to cause said adhesive to adhere to said cork and the inner face of said cap; means for applying pressure to the cork while the adhesive is in a heated state; and means for cooling said cap while pressure is applied thereto.

16. In an apparatus of the class described, the combination of a movable support provided with a plurality of pockets each adapted to receive a bottle cap containing a disk of adhesive and a layer of cork; a reciprocating device for cutting an annular groove in said cork; mechanism for forming a flanged circular metal plate; a device for forcing the flange of said plate into said groove; means for moving said support to successively position said cap beneath said groove-cutting device and then beneath said plate-forcing device; a series of gas jets; and a chain for carrying said caps over said jets to permit the heat therefrom to act upon said adhesive.

17. In an apparatus of the class described, the combination of a movable carrier provided in its upper face with a plurality of perforated recesses each adapted to support a bottle cap containing a layer of cork and a disk of adhesive between said cap and cork; means for supplying heat located beneath said movable carrier; and means for moving said carrier into position for the caps thereon to be acted upon by said heat.

18. In an apparatus of the class described, the combination of a movable carrier provided in its upper face with a plurality of perforated recesses each adapted to support a bottle cap containing a layer of cork and a disk of adhesive between said cap and cork; means for supplying heat located beneath said movable carrier; means for moving said carrier into position for the caps thereon to be acted upon by said heat; and means for applying pressure to said caps while said adhesive is in heated state.

19. In an apparatus of the class described, the combination of a movable carrier provided in its upper face with a plurality of perforated recesses each adapted to support a bottle cap containing a layer of cork and a disk of adhesive between said cap and cork; means for supplying heat located beneath said carrier; means for moving said carrier into position for the caps thereon to be acted upon by said heat; means for applying pressure to said caps while said adhesive is in heated state; and means located beneath said carrier for cooling said caps while under pressure.

20. In an apparatus of the class described, the combination of an endless chain carrier each link of which is adapted to support intermediate its ends a bottle cap containing a layer of cork and a disk of adhesive between said cap and cork; means for supplying heat; and means for moving said carrier into position for the caps to be acted upon by said heat.

21. In an apparatus of the class described, the combination of an endless movable carrier provided in its upper face with a plurality of perforated recesses each adapted to support a bottle cap containing a layer of cork and a disk of adhesive between said cap and cork; a plurality of gas jets for supplying heat; and means for moving said carrier into position for the caps thereon to be acted upon by said heat.

22. In an apparatus of the class described, the combination of an endless carrier each link of which is provided with a recess in its upper face intermediate its ends adapted to support a bottle cap containing a layer of cork and a disk of adhesive between said cap and cork; a plurality of gas jets for supplying heat located beneath said carrier; means for moving said carrier into position for the caps to be acted upon by said heat; and means for subsequently cooling said caps.

23. In an apparatus of the class described, the combination of an endless movable carrier provided with a plurality of recesses in its upper face each adapted to support a bottle cap containing a layer of cork and a disk of adhesive; a plurality of gas jets; a perforated air pipe for supplying a blast of cold air; means for moving said carrier over said jets and then over said air pipe; and means moving in unison with said carrier for applying pressure to said cork layers in said caps while passing over said air pipe.

24. In an apparatus of the class described, the combination of an endless chain carrier each link of which is provided in its upper face intermediate its ends with a recess adapted to support and position a bottle cap containing a layer of cork and a disk of adhesive; a plurality of gas jets located be-

neath said carrier; a perforated air pipe also located beneath said carrier for supplying a blast of cold air; means for moving said carrier over said jets and then over said air pipe; supporting guides for said carrier; and means moving in unison with and above said carrier for applying pressure to said cork layers in said caps while passing over said air pipe.

25. In an apparatus of the class described, the combination of an endless chain carrier each link of which is provided in its upper face intermediate its ends with a recess adapted to support a bottle cap containing a layer of cork and a disk of adhesive; a plurality of gas jets located beneath said carrier; a perforated air pipe also located beneath said carrier adapted to supply a blast of cold air; means for moving said carrier over said jets and then over said air pipe; perforated supporting guides for said carrier; and means moving in unison with said carrier for applying pressure to said cork layers in said caps while passing over said air pipe.

26. In an apparatus of the class described, the combination of an endless carrier provided in its upper face intermediate its ends with a plurality of recesses each adapted to support a bottle cap containing a layer of cork and a disk of adhesive; a plurality of gas jets located beneath said carrier; a perforated air pipe also located beneath said carrier for supplying a blast of cold air; means for moving said carrier over said jets and then over said air pipe; a second carrier moving in unison with said endless carrier and provided with a plurality of pressure members adapted to enter said caps; and a pressure bar above said air pipe adapted to act on said second carrier to apply pressure to the cork layers in said caps while passing over said air pipe.

27. In an apparatus of the class described, the combination of a carrier provided in its upper face with a plurality of perforated recesses each adapted to support a bottle cap containing a layer of cork and a disk of adhesive; guides therefor; a plurality of gas jets; a perforated air pipe for supplying a blast of cold air; means for moving said carrier over said jets and then over said air pipe; a second carrier provided with a plurality of pressure members adapted to enter said caps; a pressure bar above said air pipe adapted to act on said second carrier to apply pressure to the cork layers in said caps while passing over said air pipe; and means for adjusting said pressure bar toward and from said guides.

28. In an apparatus of the class described, the combination of a carrier provided in its upper face with a plurality of perforated recesses each adapted to support a bottle cap containing a layer of cork and a disk of adhesive; guides therefor; a plurality of gas jets; a perforated air pipe for supplying a blast of cold air; means for moving said carrier over said jets and then over said air pipe; a second carrier provided with a plurality of pressure members adapted to enter said caps; a pressure bar above said air pipe adapted to act on said second carrier to apply pressure to the cork layers in said caps while passing over said air pipe; means for adjusting said pressure bar toward and from said guides; and mechanism interposed between said carriers to drive them in unison.

29. In an apparatus of the class described, the combination of a perforated table; a device for feeding a strip of material into position over the perforation in said table; a reciprocating punch adapted to enter said perforation and cut a blank from said strip of material; a spring-pressed plunger in said punch, with its outer end normally beyond the end of said punch but adapted to be withdrawn a limited distance within said punch; means coöperating with said punch and plunger and in axial alinement therewith to form a flange on said blank; and a rotatable member beneath said table provided with a pocket adapted to receive said blank.

30. In an apparatus of the class described, the combination of a perforated table; a device for feeding a strip of material into position over the perforation in said table; a reciprocating punch adapted to enter said perforation and cut a blank from said strip of material; a spring-pressed plunger in said punch, with its outer end normally beyond the end of said punch but adapted to be withdrawn a limited distance within said punch; a second plunger coöperating with said punch and plunger and in axial alinement therewith to form a flange on said blank; and a rotatable member beneath said table provided with a pocket adapted to receive said blank.

31. In an apparatus of the class described, the combination of a perforated table; a device for feeding a strip of material into position over the perforation in said table; a reciprocating punch adapted to enter said perforation and cut a blank from said strip of material; a spring-pressed plunger in said punch, with its outer end normally beyond the end of said punch but adapted to be withdrawn a limited distance within said punch; means coöperating with said punch and plunger to form a flange on said blank; a rotatable member beneath said table provided with a yielding annular member adapted to receive said flanged blank and provided with an annular lip on its under face; a support for a bottle cap provided

with a lining of cork having an annular groove in its face; and a reciprocating member adapted first to force said lip into said annular groove in the cork lining of said cap and then force the flange of said blank into said groove.

32. In an apparatus of the class described, the combination of a perforated table; a device for feeding a strip of material into position over said perforation in said table; a reciprocating punch adapted to enter said perforation and cut a blank from said strip of material; plungers on opposite sides of said blank for forming a flange thereon; a rotatable plate beneath said table provided with a pocket adapted to receive said flanged blank; means for depositing said flanged blank in said pocket; means for rotating said plate to position said pocket above a supported cork-lined bottle cap; a plunger above said pocket; and means for operating said plunger to force the flanged blank from said pocket into the cork lining of said cap.

33. In an apparatus of the class described, the combination of a reciprocating member; a perforated table beneath said member; a device for feeding a strip of material over and of the same diameter as the perforation in said table; a punch over said perforation moved by said reciprocating member and adapted to cut a blank from said strip of material; a spring-pressed plunger within said punch of the same diameter as the finished cap to be made from said blank; means for limiting the movement of said plunger in either direction relative to said punch; a second plunger beneath said perforation having a radius less than the radius of the upper plunger equal to the thickness of said strip of material; a pivoted lever connected to said second plunger; and a divided member between said lever and reciprocating member providing a means whereby only the latter part of the movement of said reciprocating member is imparted to said second plunger.

34. In an apparatus of the class described, the combination of a support for a bottle cap containing a cork lining; means for cutting an annular groove in said cork; means for forming a flanged metal protecting plate; means for separating the walls of said annular groove; and means for forcing said flange of said plate into said groove.

35. In an apparatus of the class described, the combination of a support for a bottle cap containing a cork lining; means for cutting an annular groove in said cork; means for forming a flanged metal protecting plate; means for separating the walls of said annular groove; and means for forcing said flange of said plate into said groove while the walls of said groove are separated.

36. In an apparatus of the class described, the combination of a support for a bottle cap containing a cork lining; means for cutting an annular groove in said cork; means for forming a flanged metal protecting plate; a member with an annular wedge lip for separating the walls of said annular groove; and means for forcing said flange of said plate into said groove while said wedge lip remains in said groove.

37. In an apparatus of the class described, the combination of a support for a bottle cap containing a cork lining; of means for cutting an annular groove in said cork; means for forming a flanged metal protecting plate; a member with an annular wedge lip for separating the walls of said annular groove; and a reciprocating plunger for forcing said flange of said plate into said groove while said wedge lip remains in said groove.

38. In an apparatus of the class described, the combination of a rotatable dial provided with an opening therethrough; a support for said dial provided with an annular groove; a plunger in said opening adapted to travel in said groove with its top forming the bottom of a pocket adapted to receive an inverted bottle cap lined with cork; means for subjecting the cork to pressure; means for inserting a metal protector plate into said cork; and a cam in said groove adapted to lift said plunger in the rotation of said dial and remove said cap from said pocket.

39. In an apparatus of the class described, the combination of two rotatable dials, the edge of one of which projects over the edge of the other and is provided with a pocket extending therethrough adapted to receive a protector plate, while the edge of the other is provided with a plurality of pockets each adapted to receive a bottle cap lined with cork; a reciprocating member above said dials; pins on said member for preventing the rotation of said dials during the reciprocation of said member; a cutter on said member for cutting an annular groove in said cork; means for supplying a protector plate to the pocket in the upper dial; and means secured to said reciprocating member for forcing said protector plate from said pocket into said cork.

40. In an apparatus of the class described, the combination of two rotatable dials, the edge of one of which projects over the edge of the other and is provided with a pocket extending therethrough adapted to receive a protector plate, while the edge of the other is provided with a plurality of pockets each adapted to receive a bottle cap lined with cork; a reciprocating member above said dials; pins on said member for preventing the rotation of said dials during the reciprocation of said member; a cutter on said

member for cutting an annular groove in said cork; means for supplying a protector plate to the pocket in the upper dial, means secured to said reciprocating member for forcing said protector plate from said pocket into said cork; and means for expelling said caps from said pockets.

UNITED STATES PATENT OFFICE.

GEORGE F. KNOX, OF MILWAUKEE, WISCONSIN.

CROWN-CORK SEAL.

1,129,578. Specification of Letters Patent. Patented Feb. 23, 1915.

Application filed March 6, 1913, Serial No. 752,370. Renewed January 13, 1915. Serial No. 2,071.

To all whom it may concern:

Be it known that I, GEORGE F. KNOX, a subject of the King of England, and resident of Milwaukee, in the county of Milwaukee and State of Wisconsin, have invented certain new and useful Improvements in Crown-Cork Seals; and I do hereby declare that the following is a full, clear, and exact description thereof.

The primary object of my invention is to provide simple means for increasing the efficiency in sealing vessels wherein the crown cork type is employed, such increased efficiency being at the same time accomplished without increasing the cost of manufacture.

Specific objects of my invention are to provide two or more annular contact points about the mouth rim of a vessel or bottle, which points are adapted to be engaged by the cork disk that is employed in conjunction with the standard metallic crown, whereby the contact points referred to constitute a multiple seat which will thus insure the desired hermetic seal, and to provide a non-porous facing sheet for the cork disk, wherein the seal is employed in bottling mineral waters, charged beverages or the like, the facing sheet serving to prevent contact of the liquid with the cork body and its consequent detrimental effects.

With the above and other minor objects in view the invention consists in certain peculiarities of construction and combination of parts as set forth hereinafter with reference to the accompanying illustrations and subsequently claimed.

In the drawings Figure 1 represents an enlarged sectional elevation of a bottle-head and cap-closure therefor embodying the features of my invention; Fig. 1ª, a similar fragmentary section, the section being taken upon a line intersecting a pore of the cork filler to more clearly illustrate the effect of closing said pore incidental to pressure being applied to the cap; Fig. 2, a similar fragmentary sectional view of a cap closure embodying the features of my invention, showing the application thereto of a pliable facing sheet, whereby the cork is insulated from the liquid contained within the bottle; Fig. 2ª, a similar sectional view illustrating the cap-closure after it is subjected to pressure and expansion by heat, whereby the facing sheet is separated at the point subjected to the greatest strain; Fig. 3, a fragmentary plan view of one form of pliable facing sheet embodying the features of my invention; Figs. 4 and 4ª, fragmentary sectional views exemplifying a sealing operation wherein a standard type of crown cork and bottle is employed, the said views illustrating the effect produced upon a porous cork in conjunction with the rim of a bottle having a single point of contact, and Fig. 5, a sectional view of another form of my invention.

Referring to the exemplification of the prior art as illustrated in Figs. 4 and 4ª of the drawings, in ordinary crown corking and sealing it has been found in practice that owing to the spongy or porous consistency of the cork disk *a* when said disk is subjected to sufficient pressure upon the high face *b* of the curved rim of a bottle-head, the said curved rim constitutes a single point of contact or ridge. In such cases the tendency of the cork disk is to break or open at the point of contact and thus the seal is rendered imperfect, resulting in a large percentage of the bottled product being damaged by exposure to atmospheric conditions. Thus it will be seen that unless the face of the cork be absolutely perfect, the single contact point of its engagement with the rim of the bottle will not effect a hermetic seal. This tendency of the cork disk to break at the seating point or ridge is still further increased should a hole *c*, constituting one of the pores of the disk, be alined with the seating point, in which instance the pressure and expansion or swelling of said disk due to steaming, tends to open up or exaggerate the pore, causing breakage of the disk at this weakened point, whereby leakage will occur about the mouth-rim as indicated by the arrow in Fig. 4ª. Thus the purpose of my invention is to overcome the above objections and supply a multiplicity of seating faces whereby, should a hermetic seal not be effected by the first one of the seating faces or beads, the leakage will be cut off by one or the other of the auxiliary contact points, there being preferably three in number.

Referring by characters to the drawings, Figs. 1 to 3 inclusive, 1 represents a portion of the neck and head of a bottle, and 2 the crown-bead thereof, which bead merges into a rim 3 that is formed about the bottle mouth. The rim 3, as shown, is provided

with an intermediate annular V-shaped groove 4, which groove divides said rim into parallel inner and outer semicircular beads 5 and 5′ constituting high smooth points of contact. Hence it will be seen that the rim face is formed with a centrally disposed V-shaped annular groove, the inclined walls of which are tangentially merged into the opposite inner circular walls of the beads, whereby the high surfaces are smoothly rounded and are joined by the tangential faces constituting the wall grooves.

A represents a standard cork disk that is seated within the usual metallic crown B, the apron C of which crown is adapted to be contracted about the mouth rim 3 by subjecting the crown to inward pressure through a suitable die, co-incident with a downward pressure thereof, this capping operation being ordinarily employed and forms no part of my invention.

In Fig. 1 the cork disk A is shown in dotted lines, in the position it assumes prior to pressure being applied thereto, with its lower face resting upon the high points or beads of the mouth rim, the formation assumed by said disk, after it is subjected to pressure, being shown in full lines in said view. Hence it is apparent that when the cork disk is expanded it will fill out all the crevices about the face of the rim, whereby it is forced snugly down into the groove 4 and also about the walls and high points of the rim beads 5 and 5′, whereby three distinct points of contact between the rim and cork will result and owing to the fact that the center point of contact is upon a lower or different plane than that of the inner and outer contact points, a perfect hermetic seal will result. This seal is rendered impregnable due to the fact that should the first or inner seal between the ridge 5 and cork be defective further leakage of gases or liquid will be cut off by the base of the groove, which forms a central seal in connection with the expanded cork. It follows that should this seal in turn be defective that the outer seal between the cork and ridge 5 would produce the desired results, making in all a triple seal which for practical purposes is sufficient to insure perfect bottling under the most disadvantageous conditions.

It is obvious that, owing to the uninterrupted high and low surfaces of the rim, when the crown cork is expanded in the usual manner by heat, the particles of the swollen cork are capable of flowing in both directions over the semicircular beads to fill the V-shaped groove without any tendency of breaking the cork member.

To prevent the contamination of mineral waters or the like through contact with the cork disk I provide a pliable facing sheet 7 for the disk as shown in Fig. 2, the same being preferably composed of tinfoil or like substance and is of an approximate diameter corresponding to the diameter of the disk, being shown lapped about its edges.

As shown in Fig. 2, when the crown and cork disk, equipped with the metallic facing sheet, is inserted over the mouth of the bottle and thereafter subjected to pressure, as shown in Fig. 2ª, the result of said pressure and steaming will cause the cork to swell downwardly to fill the annular groove 4 as previously stated. It is apparent that such downward swell of the cork within the groove will cause the facing sheet 7 to break at this point due to the fact that the high ridges 5 and 5′ on either side of the groove have, in conjunction with the cork disk, effected a double grip upon said facing sheet. When this separation of the facing sheet takes place the cork fiber at the base of the groove is exposed, whereby a seal is effected at this point between the naked cork and vitreous material from which the bottles or vessels are ordinarily formed. It is also apparent that while a cork joint is effected at the center of the rim, the remaining two high points of contact formed by the ridges 5 and 5′ are sealed metallically by the interposed surfaces of the facing sheet, the inner metallic seal being sufficient to prevent the leakage of liquid from the vessel or its contact with the cork surface, whereby acids are generated incidental to the exposure of the cork fiber with said liquids.

As shown in Fig. 3, I may, in some instances, provide the pliable metallic facing sheet 7 with some form of circular perforation 8 adjacent to its edge or otherwise score the sheet in such manner that it will separate under pressure and expansion of the cork, upon the weakened line, the separation leaving the facing sheet in the form of a disk, the edges of which are gripped by the ridge 5 and a detachable ring portion 8′ will form a metallic outer sealing joint in conjunction with the ridge 5′.

Referring to Fig. 1ª of the drawings the cork disk is illustrated as having a hole or pore *c* therein, which pore is centrally alined with relation to the rim-groove 4. In this position the pore *c* referred to will tend to close up under the compression and steaming operation incidental to capping the bottle, due to the fact that the fiber of the cork in expanding into the groove, will flow downward as indicated upon opposite sides of said pore, thus tending to contract the same instead of expanding as in instances previously described wherein a pore of the cork is inadvertently alined with the single compression point of a bottle rim.

It is also apparent, as shown in Fig. 5, that the crown cap may be formed with a circular male bead *d* which will forcibly mold the cork disk downwardly into the

groove 4 of the vessel mouth rim. In this instance the cork disk is made in the form of a ring *a'* and the center portion of the crown B is depressed in such manner that when the closure is seated against the bottle rim the depressed metallic portion of the crown enters the mouth of the bottle and thus the disk *a'* or gasket is housed whereby fine particles of the cork which would tend to slough off are prevented from dropping into the liquid. The depressed portion of the crown cap also serves to present a metallic face to the liquid which is desirable as previously stated when the container is used in connection with mineral waters or the like.

I claim:

1. A vessel for crown corks having a mouth-rim provided with a closure seat comprising inner and outer semicircular beads, and a centrally disposed annular V-shaped groove, the oblique side-walls of the groove being tangentially merged into the opposite inner terminals of the semicircular beads, whereby a crown cork is capable, when expanded, of unobstructedly flowing in opposite directions about the semicircular beads into the V-shaped groove to fill the same.

2. A seal-joint comprising a vessel-mouth provided with a rim, a plurality of spaced annular sealing surfaces formed in the rim, a cap-inclosed sealing disk adapted to be seated upon the rim, and a pliable metallic facing sheet for the disk interposed between said disk and seating surfaces of the rim, the said sheet being weakened upon a line intermediate of the seating surfaces.

In testimony that I claim the foregoing I have hereunto set my hand at Milwaukee, in the county of Milwaukee and State of Wisconsin, in the presence of two witnesses.

UNITED STATES PATENT OFFICE.

FREDERICK RECHT, OF NEW YORK, N. Y., ASSIGNOR TO REX CAP AND CORK COMPANY, OF NEW YORK, N. Y., A CORPORATION OF NEW YORK.

CAP FOR BOTTLES.

No. 796,356 Specification of Letters Patent. Patented Aug. 1, 1905.

Application filed March 23, 1905. Serial No. 251,697.

To all whom it may concern:

Be it known that I, FREDERICK RECHT, a citizen of the United States of America, and a resident of the borough of Brooklyn, in the city of New York, county of Kings, and State of New York, have invented certain new and useful Improvements in Caps for Bottles, of which the following is a specification.

This invention is an improvement upon that class of bottle-sealing devices wherein one side of a suitable sealing medium in the form of a flat disk is held in sealing contact with the mouth of a bottle by means of pressure which is maintained against the opposite side of the disk. This pressure is maintained, preferably, by a metal cap, which is locked to the bottle in some suitable manner. The cap is usually formed of tinned iron, commonly known as "sheet-tin," as this possesses the requisite strength, can be readily formed to the required shape, provided with suitable locking devices, and is the least expensive material which possesses these properties to the required degree. The disk, which is the sealing medium and has heretofore usually been of cork, must have several properties—namely, first, compressibility and elasticity—that is to say, elasticity of volume—so that it will readily conform to the mouth of the bottle and maintain a sealing contact; second, tenacity and a sufficiently-uniform structure without exceptionally hard or soft spots and free from cracks or pores; third, resistance to solubility or chemical reaction, which would cause it to taint such liquids as are to be placed in the bottle. These are properties which are present to a sufficient degree in cork only in carefully-selected cork disks and then but partially.

The object of this invention is to secure these properties in whole or in part by suitable substitutes for cork, which possess the above-recited properties in a greater degree and are less expensive. These properties are embodied in a composite disk, wherein the first-named property (elasticity of volume) is provided by a disk, preferably of wood. The second-named property (tenacity) is embodied in a metal having the requisite tenacity and uniform structure, and the third-named property (insolubility) requisite in the material which makes the actual sealing contact with the mouth of the bottle is provided in the selection of the tenacious metal when this is practicable and when not practicable or economical by a facing of foil, which for economy must be used in such thin sheets that it is wanting in the necessary tenacity.

Suitable compressible material, such as vegetable fiber, as cork or wood, is employed as a part of the structure to enable the cap to conform with more certainty to the mouth of the bottle, as such substances possess the required property of elasticity of volume; but they possess this property to the desired degree usually only when saturated with some moistening material the presence of which causes the fiber to swell and the withdrawal of which results in a shrinkage of the fiber. As the latter, if taking place after a cap has been attached to a bottle, would cause the cap to leak, provision for the prevention of such drying is desirable; and it is a further object of my invention to prevent such drying by so constructing the cap that the compressible material is wholly inclosed by metal by reason of the tenacious metal disk being made of such diameter that its periphery will lie in contact with the flange of the cap.

It is also an object of my invention to provide for the further moistening of the compressible material after the application of the cap by the provision of a recess in the compressible material, within which a suitable moistening material in solid form is contained and which will be fused and be absorbed by the compressible material when the bottle is steamed.

In the accompanying sheet of drawings, which forms a part of this application, Figure 1 is a vertical section through a cap in which the disk of metal which affords the requisite tenacity is also the sealing-disk in contact with the mouth of the bottle. Fig. 2 is a vertical section through a cap in which the disk of tenacious material is faced with foil and the foil makes the sealing contact with the mouth of the bottle. Fig. 3 is a perspective view of a disk of wood, which is the disk of compressible and absorbent material preferably employed in the cap. Fig. 4 is a perspective view of the disk of tenacious and insoluble metal employed in the form of caps shown in Fig. 1. Fig. 5 is a perspective view of the disk of tenacious metal employed in the form of caps shown in Fig. 2. Fig. 6 is a perspective view of the disk of foil employed in the form of caps shown in Fig. 2. Fig.

7 is a vertical section through a cap and the mouth of a bottle to which the cap is applied.

The invention is illustrated in connection with a bottle-cap of the general type heretofore patented by me in United States Letters Patent No. 646,627, dated April 3, 1900, and modified as set forth in my pending application for Letters Patent of the United States, Serial No. 223,087, filed September 2, 1904.

The cap A is formed conveniently of tinned iron, preferably of a thickness of about twelve thousandths of an inch for ordinary bottles requiring a cap of about one and one-eighth inches in diameter and applied to the mouth *b* of a bottle B. The bottle-mouth is formed with an outwardly-projecting lip *a*, which surrounds the outer periphery of the mouth of the bottle. The cap has a depending flange *d* and a bead *e*, with an inwardly-facing annular groove formed around the lower margin of the depending flange. A wire D is placed in the groove, and when the cap is placed on the bottle the wire partly underlies the lip of the bottle, and the consequent engagement of the bead with the lip of the bottle, preferably through the interposed wire, securely holds the cap over the mouth of the bottle.

In the form shown in Fig. 1 two disks are employed within the metal cap, so that when the cap is placed over the mouth of a bottle they will be interposed between the cap and the mouth of the bottle. One of the disks is of an absorbent compressible material E, for which I find a soft close-grained wood, such as basswood, well adapted. This wood is preferably employed in a moist form, being saturated with melted paraffin, glycerin, or a heavy oil or other substance which is comparatively non-drying, lubricating in character, and not destructive of the fiber. A recess *f* is shown in the disk in which a reserve supply of the moistening material, preferably in solid form, as paraffin *p*, is placed, where it will be melted and absorbed by the wood after the cap has been placed on the bottle during the usual process of steaming the bottle. The disk of compressible material may be of other substance than of wood, as good sealing can be effected when the disk is of ground-cork sheeting, as linoleum, or thick pasteboard or rubber. The other disk K within the metal cap is of a suitable metal—as zinc, aluminium, tin, or alloy—which will not be attacked or dissolved or noticeably taint the contents of the bottle. It is of such thickness, usually three to five thousandths of an inch, and of such tenacity that when the requisite pressure is applied for affixing the cap and the metal disk is clamped between the wood disk and the mouth of the bottle the metal disk will properly fold and adjust itself to the mouth of the bottle without tearing and effect a proper sealing contact. The metal disk is of greater diameter when flat than the inside of the vertical part of the flange of the cap, and its entire periphery is in contact with the flange, so that when the cap is placed on the bottle and the disk somewhat corrugated in conforming to the mouth of the bottle and driven within the vertical part of the flange of the cap the periphery of the disk will still be in contact with the flange, thereby sealing the disk of wood in the cap so that no part of the wood will be exposed to changing air, and drying of the wood will thereby be prevented. The disk also prevents the ingress and egress of water, which would otherwise gain access in the process of steaming, for water by reason of the readiness with which it evaporates and the difficulty of retaining it in uniform amount in the fibers of the wood is less suited than other substances above named as a moistening material.

In the form shown in Fig. 2 a tenacious metal disk K′, which in this form need not be of an insoluble material, is faced with foil F, preferably of pure tin or tin alloy, which is not attacked or dissolved by the contents of the bottle. In this structure the tenacious metal disk is of importance, as it supports the foil and relieves the foil of such strain as would cause it to tear if it were in direct contact with the wood. The unqualified expression "a tenacious metal disk" is therefore to be understood, broadly, as inclusive both of the structure of Fig. 1, wherein the property of tenacity is present in a metal suited for direct sealing contact and exposure to the bottle contents, and in the structure of Fig. 2, wherein the tenacious metal disk is composite and consists of two metals, one of which imparts to the disk the requisite tenacity and the other of which has properties which render it suitable for direct sealing contact.

As compared with bottle-caps in which well-selected cork is the sealing medium a somewhat greater pressure is requisite in capping bottles with caps constructed in accordance with this invention to make the aluminium disk conform to the irregularities of the bottle-mouth and be brought into proper sealing contact therewith. However, this pressure is no greater than is required in effecting the locking engagement of the cap and bottle with the form of lock herein set forth by the method of applying pressure to the bead for the double purpose of first effecting the sealing engagement and then turning the bead inwardly to carry it and the locking-wire into engagement with the lip of the bottle, as set forth in my application for Letters Patent of the United States, Serial No. 223,088, filed September 2, 1904, for a machine for applying caps to bottles. The strain of this pressure is transmitted through the flange, which is a separate element from the sealing-disk, of greater tensile strength by reason of the employment of a metal either of greater unit strength or greater thickness, or both.

The tin cap and the interposed disk of compressible material have a further function in shielding the sealing-disk when on the bottle.

What I claim as new, and desire to secure by Letters Patent of the United States, is—

1. The combination with a metal cap adapted to be locked over the mouth of a bottle, of a tenacious metal disk contained within the cap, and a disk of compressible material interposed between the cap and metal disk, the whole organized to effect a sealing contact between the metal contained in the cap and the mouth of the bottle.

2. The combination with a metal cap adapted to be locked over the mouth of a bottle, of a tenacious metal disk contained within the cap, a facing of foil for the disk, and a disk of compressible material interposed between the cap and tenacious metal disk, the whole organized to effect a sealing contact between the foil and the mouth of the bottle.

3. The combination with a metal cap adapted to be locked over the mouth of a bottle, of a metal disk the periphery of which is in contact with the flange of the cap, a disk of absorbent compressible material and a suitable moistening material, the disk of the compressible material and moistening material being wholly inclosed by the cap and metal disk.

4. The combination with a metal cap adapted to be locked over the mouth of a bottle, of a metal disk contained within the cap, a disk of absorbent compressible material provided with a recess and a suitable moistening material in solid form but fusible at a low temperature contained within the recess, the disk of compressible material and moistening material being wholly inclosed by the cap and metal disk.

5. The combination with a bottle, of a metal cap adapted to be locked over the mouth of the bottle, a tenacious metal disk contained within the cap, and a disk of compressible material interposed between the cap and metal disk, the whole organized to effect a sealing contact between the metal contained in the cap and the mouth of the bottle.

6. The combination with a bottle, of a metal cap adapted to be locked over the mouth of the bottle, a tenacious metal disk contained within the cap, a facing of foil for the disk, and a disk of compressible material interposed between the cap and tenacious metal disk, the whole organized to effect a sealing contact between the foil and the mouth of the bottle.

7. The combination with a bottle, of a metal cap adapted to be locked over the mouth of the bottle, a metal disk the periphery of which is in contact with the flange of the cap, a disk of absorbent compressible material and a suitable moistening material, the disk of the compressible material and moistening material being wholly inclosed by the cap and metal disk.

8. The combination with a bottle, of a metal cap adapted to be locked over the mouth of the bottle, a metal disk contained within the cap, a disk of absorbent compressible material provided with a recess and a suitable moistening material in solid form but fusible at a low temperature contained within the recess, the disk of compressible material and moistening material being wholly inclosed by the cap and metal disk.

Signed by me at New York, N. Y., the 21st day of March, 1905.

FREDERICK RECHT.

Albin H. Warth

(Write first name in full.)

Specification

To All Whom It May Concern

Be It Known, that I, Albin H. Warth

a citizen of the United States,

residing at Baltimore in the [redacted]

State of Maryland have invented new and useful

improvements in

Bottle Cap Spot Material

of which the following is a specification:

1671
1949

This invention relates to a method of producing closures of the type in which a sealing disk has a facing.

This application is a division of my co-pending application, Serial No. 159,745, filed January 7, 1927.

Closures of the well known crown cork type comprise a metal shell having a skirt and a resilient sealing disk usually made of cork. For some uses, the sealing disks are given a facing, e. g. tin foil, or aluminum foil. Ordinarily this facing is of smaller diameter than the cork disks and such crowns are known in the trade as "spot center crowns".

These spot center crowns have been produced in various ways. According to one method a slot or groove is cut in the cork disk and the spot is given an inturned rim which is inserted in the slot. This method is objectionable because of its expense and because the tin foil spots are apt to drop out. According to another method the spots are pasted to the cork disks by a casein paste

or a glue. In crowns so made the spots tend to loosen as the paste or glue is attacked by the packages liquids. Furthermore, such method involves difficulties in handling and in applying the paste or glue. According to still another method, the spots are secured by an underlying and separately formed and deposited tissue of gutta percha or coated paer. In crowns so made, like objections are met with.

It is an object of the present invention to provide a method of producing spot center crowns such that the spots are easily and economically secured to the sealing disks and such that they are firmly secured and not liable to become loosened in use.

With these general objects in view, the invention consists in the method which will be first described and then more particularly pointed out in the claim.

According to the method of the present invention, the strip material, such as metal foil, is coated with a substance that is devoid of tackiness when dry and has adhesive qualities when soft. In carrying out the method according to what is considered the best practice, the adhesive substance is such that it can be applied cold, i. e. at room temperatures, and is insoluble in cold water. While various materials may be used, I have found a suitable adhesive in a solution of damar gum and rosin in mineral spirit or turpentine, to which is added 5% or less of a vegetable oil, such as soya bean or china-wood oil. The damar gum and rosin may be in the proportion of 35% to the whole. The adhesive may have a drier of lead resinate or the like in a proportion of 2% or less.

While the coating may be applied to the material

in various ways, it is conveniently applied in fluid form and cold to a strip of foil from which the spots are to be cut. In this connection it is noted that the spots may be conveniently assembled by feeding a strip of material over successive crown corks and cutting out a disk which is deposited on a cork, such assembling machinery being known in the art.

After the coating is applied to the material, it is dried. While this may be effected by air drying at room temperatures, it is more rapidly accomplished at a temperature of about 300° F maintained for about three minutes. When dried the coating is devoid of tackiness so that the metal foil may be handled without difficulty or trouble. This is particularly advantageous when the metal foil is to be fed in strips because the application of the adhesive is carried out independently of the assembling steps. Moreover, the coating gives the thin metal foil more or less body which facilitates feeding and cutting.

In case the metal foil is fed in a strip, spots may be cut out and deposited on the sealing disk, as above set forth.

At the time of assembly the coating material is softened to render it adhesive and the assembled unit is subjected to pressure. In carrying out the invention according to what is now considered the best practice, the coating will be softened by heat after the crown is assembled. This may be accomplished in any suitable manner, as by a heated plunger or a plunger and heated table. The heat softens the coating and renders it adhesive and the pressure serves to unite the spot to the cork.

The assembled unit is then cooled and the cooling may advantageously be coupled with pressure, for example,

by a plunger. Cooling may be effected in any suitable manner, being carried out to the congealing point of the coating material.

It may be desirable to secure the spot in position, prior to the heat and pressure steps, sufficiently to prevent dislodgement of the spot during any interval between assembling and final sticking. This may be accomplished, for example, by preheating the assembled crown, to soften the coating, as soon as the metal foil spot is deposited. ~~On the coating may be softened by moistening slightly with a solvent, such as benzol.~~ In either case the coating becomes tacky enough to hold the metal foil spot from getting out of position during ordinary passage through assembling apparatus.

The resulting crown has a firmly secured metal foil spot which is not liable to become loose in use, owing to the fact that the adhesive substance is not soluble in liquids more commonly sealed by crown corks. Moreover, when the metal foil is assembled with the sealing disk, it is already prepared for being stuck in place, the sticking being accomplished by the simple application of heat and pressure. The coating operation is a simple one and the coated metal foil is easily handled because the dry coating is not tacky.

1675

1953

I CLAIM:-

As a new article of manufacture, laminated material in sheet or strip form for the spotting of cushion disks or caps, and comprising a layer of waterproof adhesive which is hard at room temperature but fuses upon the application of heat, and material to which said adhesive is bonded to form a coating, said material being impervious to moisture and acid-resistant, thereby providing laminated sheet or strip material from which laminated spots or facings may be punched for assembly with cap disks and adapted to be united with the disks by the mere application of heat and pressure.

Hon. Commissioner of Patents,
Washington, D. C.

Sir:

We hereby authorize and request entry of the following amendments in the above entitled application.

Please enter the accompanying drawing.

IN THE SPECIFICATION

Page 2

Line 5 insert the following: -This type of closure

a' is characterized by the provision, upon the interior cushion or sealing disc, of a facing or spot having a surface which protects the cushion material from the liquids and gases.

Line 10 before the period insert --, these materials

a² or other materials of protective character being suitable to provide a non-absorbent, gas impervious, and acid resistant facing.

Page 3

Line 8 after the period insert the following: -For

a³ example, one difficulty in applying discs made from separate strips, such as gas and acid resistant material and the adhesive tissue strips, has arisen from the necessity for feeding the two strips to the punching and assembly machine. There is not

only difficulty in feeding the strips, but in cutting the separate tissue strip with a clean, sharp edge so as to insure the binding stratum of adhesive being coextensive in area with the disc of liquid resistant material. As will be understood, the adhesive stratum is intended to act not only as a cement, but also as a waterproof, non-absorbent, gas impervious medium for avoiding the possibility of the contents of a bottle getting between the facing disc and the material of the cap, either the metal shelf itself or a cushion disc of cork or composition cork.

Furthermore, when using superimposed strips of the facing material and of adhesive tissue, it was essential, to bond the adhesive tissue to both the material of the cushion disc in the cap and the facing material.

In preparing the rolls of facing material and adhesive tissue, the practice usually followed was to form a roll of the tissue in strips of the desired width, and to unwind this roll and a roll of the facing material while feeding the two strips one over the other into the disc forming and assembling machine. This is a troublesome and expensive operation, because of the frequent breakage of the adhesive tissue and the necessity for using fairly heavy tissue to minimize this tendency. This is due partly to the fact that the facing material was substantially non-elastic, while the adhesive tissue possessed a certain degree of elasticity, thus introducing a factor of difficulty in securing a uniform paying of both the facing strip and the gutta percha tissue strip.

It is desirable, in the use of facing disks of the character above referred to, that the adhesive stratum be as thin as possible, and yet be continuous throughout the entire area of the facing disk, and particularly that it be uninterrupted about

the edge of this disk, since at this point the disk should be firmly bonded so as to effectively seal the joint about the edge of the facing disk. When cutting and applying the disks of material and adhesive, there is no means of ascertaining whether the desired conditions are present in the completed cap. Consequently, there is always likelihood of imperfectly faced caps being produced.

With the above conditions in mind, I have provided material in strip form, for facing bottle caps, in which one surface of the strip is provided with a firmly adherent, continuous thin facing of adhesive, thus avoiding all necessity for assembling strips of facing material and of adhesive tissue preparatory to their use in the bottle cap facing machine, and all of the disadvantages growing out of this practice.

In the strip material of my invention, a very thin stratum of adhesive is evenly distributed upon one face of a strip of facing material. The adhesive is not only firmly bonded to this material, but has a smooth surface finish of sufficient thickness to form the desired firm bond between a disk cut from the strip and the material of the cap to which such disk is cemented.

Furthermore, adhesive tissue must be of a thickness to have sufficient inherent strength to permit of its being stripped from a roll in a mill for working same, and to admit of its being cut to the desired width and to be handled in the winding and the disk applying machines, and during the process of its production it has more or less of a longitudinally extending grain, as distinguished from its normal granular formation.

In the application of heat, when bonding the facing material to the cap, when utilizing adhesive tissue, a tendency

of the adhesive is to break up into slightly isolated, small globules, thus interrupting the continuity of the bonding stratum. Whether this is due to irregularities in the surface of the facing strip, or to a shrinkage of the adhesive tissue when fused, I have been unable to determine. In the strip of my invention, however, the adhesive is thoroughly distributed throughout one face of the facing material, and the above conditions do not develop in the subsequent handling of the strips.

Page 4

Line 3 after the period insert the following: - So far as the method of producing the strip is concerned, it is such that the effective distribution of the adhesive throughout the entire area of the facing material is assured, and this condition cannot be disturbed as a result of the cutting of discs from this material when in strip form. Furthermore, the adhesive surface may be thoroughly inspected while producing the strip material, so that any imperfect product may be discarded before it reaches the disc applying machine.

Line 19 before "In" insert the following: - Since the adhesive is applied directly to the surface of the facing or spot material and firmly bonded thereto, there is no likelihood of difficulties arising as a result of separation of the adhesive from the facing strip during the spot forming operation, either as a result of poor adherence or from suction or otherwise, such as frequently occurs when using superimposed strips of facing material and of adhesive tissue. Moreover, in handling this material the adhesive stratum is incapable of stretch or distortion relative to the spot strip as frequently occurs in the handling of separate strip of adhesive tissue and facing material where any stretch or distortion of the adhesive stratum results in a defective cap and when the stretch is extreme, tearing of the adhesive tissue makes necessary the

a5

stoppage of the cap machine until the strip can be repaired.

After the coating is dry, the metal foil spots are assembled, coated side down, with the sealing disks.

Page 4

Line 27 after the period insert the following:

--In cutting discs from this improved laminated strip having an adhesive stratum bonded thereto, there is no tendency toward mutilation of the adhesive layer by reason of possible drag of the cutting dies, and each disc, as delivered from the die to within a cap, will present a continuous uninterrupted adhesive surface upon the disc so as to insure, by the subsequent application of heat and pressure, a bond between the disc and the cap cushion layer coextensive in area with the disc.

a6

This possibility of securing a clean cut by the dies for forming the discs, both as to the non-absorptive and gas impervious, and as to the adhesive stratum, insures an effective bond entirely about the edge of the spot or disc, thereby presenting a continuous barrier of non-absorptive and gas impervious material at the space between the disc and the cap which will effectively prevent the seepage of gas or fluid in a bottle between the disc and the portion of the cap to which it is applied.

Line 30 after the paragraph insert the following:

--Referring to the accompanying drawings, there is shown suitable mechanism for coating the strip and for cutting discs therefrom and adhesively uniting the disc to caps at the time of the assembly of the discs with the caps. In the drawings,

a7

Figure 1 is a diagrammatical view showing the coating of the strip.

Figure 2 is a longitudinal sectional view of a fragment of the strip.

Figure 3 is a side elevational view partly in section showing one step in the assembly operation.

Figure 4 is a view similar to Figure 3 showing the spot as it is cut and adhesively united to the cap at the time of assembly.

Figure 5 is an interior face view of the completed cap, and

Figure 6 is a cross-sectional view of the cap shown in Figure 5.

The strip of facing material should have the characteristic of aluminum foil. That is to say, it should present one surface which is non-absorbent and gas impervious. This strip may be fed from a reel 10 to a reel 11, suitably separated so that the adhesive coating may be applied and hardened between the time any portion of the strip leaves the reel 10 and is wound upon the reel 11. For the purpose of applying the adhesive, the same may be maintained in a trough 12, positioned beneath an adhesive applying roll 13, between which and a roll 14, the strip passes, so that as the rolls are rotated the adhesive is applied to the undersurface thereof. As will be understood, the adhesive hardens between the time it is applied and the winding of the laminated strip upon the reel 11.

The completed spot material or liner is illustrated in Figure 2, and comprises the layer 15 of non-absorbent and gas impervious material, such as aluminum foil having on one surface the coating 16 of adhesive, which is preferably of the character hereinbefore described. This adhesive is waterproof or liquid resistant, and will be normally hard, i. e. non-tacky, at room temperature, so that the material may be conveniently handled in strip form, but quickly softens under the application of heat, becoming tacky, so that upon the application of pressure, the laminated disc will be ad-

hesively retained in the cap. The preferred method of applying the material to the cap is to utilize, at the time of assembly, both heat and pressure to unite the spot to the cork or cushion material insert or facing of the cap.

In Figures 3 and 4, there is shown a suitable mechanism for applying the disc and adhesively uniting it to the cork insert at the time the strip is punched from the disc and assembled with the cap.

The cap 17 is of the conventional crown type having an interior facing 18 of cushion material, such as composition cork retained in the cap as by an adhesive layer 17'; the cushion disc and adhesive may be applied to the cap in any suitable manner, for example as described in the patent to Marsa, No. 1,603,786, granted Oct. 19, 1926. The caps, with the cushion discs inserted therein, may be positioned beneath the cutting dies 19, 20, by means of a traveling bed 21 having suitable sockets for receiving the cap so as to position the same accurately beneath the cutting dies. The strip material for forming the spot is fed beneath the die 20 with the adhesive coating 16 facing the cap, and when the die descends it will cut from the strip, which is fed by any suitable means (not shown), a spot or facing 22 of the character illustrated in Figures 5 and 6. The spot or disc is preferably of smaller diameter than the cap facing so as to form a substantially centrally disposed spot which leaves around its edge an exposed portion of the cushion material adapted to engage the edge of a bottle neck, the spot being of sufficient size to close the bottle mouth and prevent contact of the contents with the cushion material.

As will be observed (Figures 3 and 4) as the punch 20 descends, it cuts from the strip a spot of the size shown in Figure 5, and continued downward movement presses this disc upon the cushion layer 18.

The punch 20 may be maintained at an elevated temperature, as by means of a burner 25, and the temperature should be sufficient to fuse or soften the adhesive coating and make it tacky so that, at the time the disc is assembled with the cap, the heat and pressure will cause the disc to be adhesively united to the surface of the cushion material with sufficient permanency to insure that the position will be retained and avoid likelihood of displacement of the disc thereafter.

a7

Page 5

Line 10 cancel the sentence reading "Or the coating may be soi, ened etc.,"and ending in line 11.

Last line add the following:

a8

--A cap made in accordance with this method possesses the advantage of a substantially uniform and complete distribution of the adhesive layer throughout each spot or facing disc. The method has the advantage of eliminating the labor of associating a separate adhesive strip and a strip of facing material, and the further advantage of enabling higher speeds to be maintained in the facing spot applying machine. The elimination of the danger of breakage of a separate adhesive tissue strip avoids the frequent stoppage of the machine, which was unavoidable due to the handling of the somewhat fragile and elastic adhesive tissue.

IN THE CLAIM

Line 3 before "layer" cancel "a" and substitute --an exposed continuous--

Line 5 before"material" insert --sheet like facing--

Line 6 before "coating" insert --continuous--

Line 7 cancel "and acid resistant".

REMARKS

This application has been very carefully reviewed, and has

been amended in order that the invention may be set forth in the manner described in the parent application which has now matured into patent 1,788,260.

This application covers the article of manufacture which is employed in the method defined in the claims of the patent.

The amendments entered in the specification have been offered in the light of interviews kindly granted the applicant by the Examiner, and it is believed that, in view of these amendments, the Examiner will now appreciate more clearly the real problem which applicant has solved and the definite advance he has made over the prior art.

The Examiner's attention is particularly directed to the additional matter inserted in the specification. This matter simply explains the relation of the present invention to the prior art and defines the characteristics of the material involved in the use of the method which make the method a very valuable advance over former practices.

The applicant does not claim to be the first to have used metallic foil; this material is simply one of numerous materials which have been used for years in the spotting or facing of caps. These cap facings or spots are employed in order to afford a non-absorbent, gas impervious and acid resistant surfacing for the cushion material which is used in crown caps. As the Examiner will, of course, appreciate, other materials have been used, such as paper suitably finished to impart these characteristics to the same.

At the time the applicant made the present invention, it was customary to "spot" by feeding the acid and gas resistant material in strip form, and also the adhesive tissue in strip form, and to simultaneously punch from the strips discs of the acid resistant material and of the adhesive tissue. Another practice was to deposit on the cushion material of the cap the cement or liquid adhesive, and then to apply the disc of acid resistant

material. The use of this liquid made the process slow in view of the difficulties in applying the glue or paste. Moreover, the use of a separate strip of adhesive in tissue form was objectionable for various reasons, which are now fully explained in the specification. Briefly stated, these objections were:

FIRST - it was difficult to handle the adhesive in tissue form and breakage of the same made necessary the stopping of the cap machine.

SECOND - stretching or distortion of the tissue adhesive made it difficult to obtain exact registry of the tissue disc and acid-resistant material disc when the two were applied to a cap.

THIRD - due to drag in the cutting dies, it was not always possible to obtain exactly corresponding sizes of tissue and material discs, with the result that the entire bottom surface of the material disc was not always backed with adhesive and the material disc was not always united to the cushion throughout its entire edge.

FOURTH - the necessary thickness of the adhesive tissue resulted in expression of the same from beneath the facing when pressure is applied to the spot.

FIFTH - the handling of two strips of material retarded operation of the cap assembling machine.

SIXTH - the necessary thickness of the adhesive tissue made it difficult to obtain a firm bonding of the tissue and facing material throughout the face of the disc.

SEVENTH - after the punching operation the separate discs moved out of registration and resulted in a large proportion of defective caps.

These and other objections to the previously used processes have been overcome by the applicant. His invention involved, as a primary concept, the elimination of the use of separate strips

in the cap assembly operation. As a secondary concept, it involved the provision of a unitary multi-layer strip with the layers bonded, one surface of this strip being a waterproof adhesive which will soften under the application of heat and pressure, and the other surface being acid resistant, gas impervious and non-absorbent. It has frequently been pointed out by the Courts that invention often consists in discovering what is the difficulty with existing structures or methods, and that this constitutes invention, although the means for overcoming these objections are comparatively simple. For example, Judge Hough said in the case of Kurtz et al., v. Belle Hat Lining Co. Inc., (C. C. A. 2nd Cir.) 280 Fed. 277 (at 281):

> "Patentability has often been found 'in discovering what is the difficulty with an existing structure' and correcting the same, even though 'the means' are old and their mere 'adaptation to the new purposes involves no patentable novelty.' Miehle, etc., Co. v. Whitlock, 223 Fed. 647, 650, 139 C. C. A. 201. Hindsight, or wisdom after the fact, has always been looked upon with disfavor; e. g. Faries Co. v. Brown, 121 Fed. 547, 550, 57 C. C. A. 609."

The same Circuit Court of Appeals in the earlier case of Miehle Printing Press & Mfg. Co. v. Whitlock Printing Press Co., 223 F. R. 647, said:

> "Patentable novelty is sometimes found in discovering what is the difficulty with an existing structure and what change in its elements will correct the difficulty, even though the means for introducing that element into the combination are old and their adaptation to the new apparatus involves no patentable novelty."

In these decisions the Courts simply followed other decisions to the same effect, such as Patents Selling v. Mann 204 Fed. 99; General Electric v. Hartman 187 Fed. 151; General Electric Co. v. Sangamo Electric Company (C. C. A. 7th) 174 Fed. 246. In the last case, the Court pointed out that there are two steps involved in an inventive act, namely (a) discerning

in existing machines or processes some deficiency, and (b) pointing out the means to overcome the same. The Court said this in the following language:

> "Invention, in the nature of improvements, is the double mental act of discerning in existing machines, processes, or articles, some deficiency and pointing out the means of overcoming it."

The applicant's invention, from the standpoint of conception, consisted in three steps. First, he perceived that the former practices of using (a) paste or glue, or (b) a separate strip of adhesive tissue, were cumbersome and objectionable. He saw the objections and set out to overcome them. The second step in his invention was to supply the medium and method by which these objections might be eliminated. In connection with the second step, he supplied a material of laminated character having (a) one exposed surface which is acid resistant and gas impervious, and (b) another exposed surface with a thin coating of waterproof adhesive which softens under the application of heat, but is normally hard, so that the material may be conveniently handled.

The applicant's development has numerous advantages, including the following:

> 1. The cost of product of spot crowns is very materially decreased; in fact this invention alone was the main factor in reducing the cost of production of spot crowns sufficiently to make possible commercial production.
>
> 2. There is but a single strip to handle, instead of the two separate strips of the former method.
>
> 3. There is no need of applying paste or glue to the cushion material of each cap.
>
> 4. The simultaneous cutting of the adhesive and material discs from a single strip insures that the adhesive is coextensive in area with the material with the result that there is no possibility of gas or moisture entering between the spot material and the cushion layer around the edges of the spot.

5. The thinness of the adhesive layer avoids expression of the adhesive when pressure is applied to the spot.

6. There is no tendency for distortion or stretching of the adhesive layer relative to the material strip.

7. There is no possibility of breakage of a fragile adhesive tissue which results in stoppage of the machine.

8. It is possible to inspect the facing material as it is fed into the assembly machine to insure that the entire surface is coated with adhesive, which cannot be done when the separate strips are fed or when paste or glue is first applied to the cushion material. In other words, imperfectly faced caps are virtually eliminated. There is absolute registration of the edges of the material disc and adhesive disc which is difficult to obtain in the manufacture from separate strips.

9. The discs in united form may be fed into the cap in absolute registry and assembled by the cutting punch, due to the bonded relation of the two layers.

10. The heat and pressure necessary for uniting the facing to the cap may be applied substantially simultaneously with the punching and assembly operations without waiting for inspection, since there is no danger of the adhesive and material discs moving out of registry with one another; this permits an operation in which the punch used to cut the discs may also be employed to apply the pressure.

These and other advantages of applicant's invention make the same, from a practical standpoint, a radical advance in the art. The Examiner will appreciate this from the fact that this method has been adopted by the Crown Cork & Seal Company, in lieu of formerly used articles. This Company, as the Examiner is probably aware, is the largest manufacturer in the world of crown caps.

As a further feature of the invention, the applicant proceeded to provide a method involving the use of this article. However, the article is the basis for the method. Protection having been granted for the method, it is thought that the same argument which supports the patentability of the method, applies with much greater force to the article, without which the method

could not have been provided.

THE PRIOR ART

The prior art cited by the Examiner illustrates quite well prior practices.

Koch (1,238,156) describes a cap having an external facing of foil and several underlayers which are, respectively, vulcanized rubber, tough paper and gutta percha. But there is nothing in this patent which suggests the idea of providing strip material having an external facing, such as foil or paper and another surface adhesively united thereto in the form of a water resistant adhesive which will fuse upon the mere application of heat. While the patent illustrates a final article having a foil facing and which includes, among its several underlayers, a gutta percha adhesive, it does not, in any way, suggest the material or article of manufacture which applicant is claiming.

Marsa (1,603,786) shows tin plate 10 from which caps are stamped. This tin plate has applied thereto, at intervals, spots 11 which are merely a cementing medium in the cap after it has been stamped from the cushion layer 16. Consequently, this patent does not suggest strip material having a continuous coating of heat fusible adhesive. The material disclosed is tin plate, which is the body of the cap. Consequently, it is not a cap liner, and is not adapted to serve as a cap liner or for the spotting of cushion discs. The other references are not at all pertinent, and have not been advanced by the Examiner as pertinent to this invention.

The claim has been amended to make clear that the material, such as foil or paper, is of sheet like character, and that the adhesive forms a continuous coating thereon. Moreover, the claim specifies that the materials are of the character adapted for the spotting of cushion discs, and obviously the tin plate disclosed by Marsa could not be used for the purpose of forming a liner

or a cushion disc upon a cap.

Allowance of the case is thought to be in order and is respectfully requested.

Respectfully,

Attorneys.

Applicant: Albin H. Warth

Ser. No. 494,201
Filed Nov. 7, 1930
For Bottle Cap Spot Material

Cushman, Bryant & Darby,
Loan and Trust Bldg.,
Washington, D.C.

MAILED
DEC 17 1931

Responsive to amendment filed June 16, 1931.

The following additional references are made of record:

Beer	1,023,713	April 16, 1912	154-Metal Foil
Stanley	961,550	June 14, 1910	154-Metal Foil

Th claim is again rejected on Marsa who clearly shows a metal foil coated with a fusible adhesive. While Marsa's coating is not continuous, it would be obvious to make it so.

The claimis further rejected on Stanley or Beer both of whom show metal foil coated with a thermoplastic adhesive such as resin, gum, etc. While these references do not propose to make the same use of their article as the applicant, the mere functional statement as to the use does not render an article patentable. Furthermore, it is clear that a patentee is entitled to new uses for his article.

This case should be prepared for a final action.

June 16, 1932.

Hon. Commissioner of Patents,
Washington, D. C.

Sir:-

We hereby authorize and request entry of the following amendment in the above entitled application:

IN THE SPECIFICATION:

Page 4:

Next to the last line, after the period insert the following:

B'

-- An adhesive of this character provides a highly flexible adhesive layer continuously united with the facing material. Moreover, such an adhesive is highly resistant to the acids and alkalies ordinarily present in liquids which are to be capped. This is highly important in the manufacture of spot caps, since the liquids attack the adhesive around the edge of the spot. An adhesive of this character, which is not only waterproof, but resistant to acids and alkalies as well, maintains a firm adherent union of the facing or spot material with the cork disc. Due to its flexible character, it will not crack, and, therefore, it constitutes a flexible backing for the spot material. --

1697

1975

IN THE CLAIM:

Line 1, before "laminated" insert -highly flexible-.

Line 3, after "waterproof" insert -- , flexible and acid-resistant-.

Same line (3), after "adhesive" insert --adapted to adhere to a cork disc and-.

C.B.D-C Line 3, before comma insert -- with [illegible] less weight than the disk diameter

REMARKS

The Examiner is respectfully requested to reconsider this application, since the claim has been limited in a manner which definitely confines its scope to the cap art. The claim as previously worded was rejected upon the Marsa patent, and also upon the patents to Stanley and Beer.

Marsa does not disclose flexible spotting material. Marsa shows merely sheet metal having spots of adhesive thereon. This metal is used for the formation of caps which are stamped from the metal at the points where the adhesive is applied. The disclosure in the Marsa patent is totally foreign to applicant's invention, which relates to spotting material intended to be used for producing the well known center spot type of cap. This type of cap is now a recognized species of crown cap and is universally employed for capping ginger ales and other highly acidulated beverages.

The patents to Stanley and Beer do disclose a flexible material having an adhesive thereon. But the Examiner will admit, of course, that the Stanley and Beer materials have no relation to the capping art. If applicant were claiming merely a flexible material having an adhesive thereon, these patents would, perhaps, be somewhat pertinent, and we appreciate their citation by the Examiner in order that the record may be complete.

But applicant is claiming a new article of manufacture which consists of water-resistant facing material having a

backing layer of an adhesive which is of a specific type, namely (a) flexible, (b) waterproof, and (c) acid-resistant, These are three (3) essential characteristics of applicant's article, and they are not present in the Stanley and Beer devices.

Neither of the patentees had any conception of material which would be useful in the capping art. Neither suggests an adhesive which could be practicably employed for uniting a spot to a cork disc.

Stanley contains no suggestion of a chemically resistant adhesive which could be employed for uniting either paper or tin foil to a cork disc in a bottle cap. Stanley does not mention any specific type of adhesive, although he does provide a water jacket, and, therefore, it is probable that the adhesive is a glue solution of high viscosity. Such an adhesive would be suitable for adhering metal letters to leather bags, but it would be useless in the cap manufacturing art.

Beer uses a simple water soluble gum or glue. Beer cannot use anything which would be effective in the cap art, since his final object is to strip metal foil from a surface which is purposely made non-adherent.

Such a type of adhesive would be of no use whatsoever in applying spot material to cork discs intended to be used for sealing acidulous beverages.

It is apparent, therefore, that neither Stanley nor Beer suggests the use of a flexible acid-resistant adhesive. Obviously, neither of these patentees ever thought of acid resistance. They were concerned merely with providing monograms for leather goods.

Applicant provides, however, a new article of manufacture consisting of highly flexible facing layer, of foil for example,

and a continuous adhesive layer which is equally flexible, and is also both waterproof and acid-resistant. A further characteristic of the adhesive layer is that it fuses upon application of heat and will become hard at room temperature.

It is submitted that this application discloses a radically new conception. Applicant is the first to provide spotting material in strip form having a continuous adhesive backing of the character described united thereto. The practical character and importance to the industry of applicant's conception and disclosure is apparent from the record.

Admittedly, the changes required to adapt Stanley or Beer to the capping art are small. But the ultimate fact is that neither Stanley's nor Beer's material as constituted, is suitable and a conception radically different from either of the patentees was necessary in order to perceive the advantage of applicant's idea and to complete applicant's conception. As the Courts have repeatedly said, developments of this character are not to be tested in the light of the changes made in the prior art. The changes required in prior art devices are ordinarily very simple. But the question of invention is to be determined rather by the idea which dictated the changes and the simplicity of the changes is immaterial. As Judge Learned Hand recently said in the case of H. C. White Co. v. Morton E. Converse & Son Co., involving a child's "Kiddie Car", 20 Fed. (2d) 311 (at 313) (C.C.A. 2d Cir.):

> "Again and again, ad nauseam, courts have been fond of saying that it is the obvious when discovered and put to use that most often proves invention. In such matters we look rather to history than our own powers of divination, if history is at hand. Hirsch v. Gould, 6 Fed. (2d) 793 (C.C.A.2). * * * We see in this an invention just because, be-

BLANK

PAGE

BLANK

PAGE

> ing so simple, it had not occurred to any one before. The fact that the changes were so slight is quite irrelevant, so long as they were essential to the purpose, as they were."

Again, Judge Hough considered the same question in Kurtz et al v. Belle Hat Lining Co., Inc., (C.C.A. 2d Cir.) 290 Fed. 277 (at 281):

> "Patentability has often been found 'in discovering what is the difficulty with an existing structure' and correcting the same, even though 'the means' are old and their mere 'adaptation to the new purposes involves no patentable novelty.' Mishle, etc., Co. v. Whitlock, 223 Fed. 647, 650, 139 C. C. A. 201. Hindsight, or wisdom after the fact, has always been looked upon with disfavor; e. g., Faries Co. v. Brown, 121 Fed. 547, 550, 57 C.C.A.609."

The claim now presented does distinguish from the prior art and defines the precise characteristics of applicant's article which make it suitable for the capping art to which it relates. The Beer and Stanley devices are not intended for the capping art and are not suitable for the purposes for which applicant's invention was intended. It is submitted, therefore, that the distinctions between applicant's invention and the prior art, although slight, should be viewed in relation to the fact that they make applicant's invention a highly useful and meritorious one, whereas the prior art contributes nothing practical or useful for applicant's purposes.

Very respectfully,

Attorneys for Applicant.

IN THE CLAIM

Cancel the claim and subetitute:

1793
1981

--2. As a new article of manufacture, highly flexible material in sheet or strip form for the spotting of cushion discs of caps with center spots of less diameter than the disc diameter consisting of a continuous layer of metallic foil coated on one side with an exposed continuous layer of waterproof, flexible, and acid resistant adhesive adherent to the foil and adapted to adhere to a cork disc, said adhesive being substantially non-tacky at room temperature but fusible upon the application of heat and substantially impervious to moisture whereby spots may be punched from the strip and united to the cushion discs of caps by the mere application of heat and pressure.

3. As a new article of manufacture, highly flexible material in sheet or strip form for the spotting of cushion discs of caps with center spots of less diameter than the disc diameter consisting of a continuous layer of metallic foil coated on one side with an exposed continuous layer of waterproof, flexible, and acid resistant adhesive adherent to the foil and adapted to adhere to a cork disc, said adhesive containing a rosin, damar gum and a vegetable oil and being substantially non-tacky at room temperature but fusible upon the application of heat and substantially impervious to moisture whereby spots may be punched from the strip and united to the cushion discs of caps by the mere application of heat and pressure.--

REMARKS

The interference, No. 60,878 having terminated favorably to the applicant, it is requested that this application be considered.

The claims have been redrafted along the lines discussed with the Examiner whose suggestions have been adopted and are very much appreciated.

As will be understood, this application is copending with application Serial No. 414,614, and the two applications will be issued simultaneously since neither is prior art as against the other, both inventions having been made on or about the same date. In addition to the prior art of record, applicant's attorneys have considered with the Examiner the following patents:

880,969, Butler	March	3, 1908
1,690,161, Evans	Nov.	6, 1928
739,932, Seiffert	Sept.	29, 1903.

While the patent to Seiffert (739,932) does disclose broadly metal foil having an adhesive coating, there is nothing in this patent which is suggestive of the combination recited in the claims. The first of the two new claims presented is generic for the purpose of covering either the specific adhesive disclosed or one of the same general type, e. g., gutta percha. The second claim is restricted to the specific adhesive originally disclosed.

While it may be broadly old to use gutta percha in the cap art, applicant is the first to disclose a "spotting" material comprising metallic foil as one layer and an adherent coating of a flexible adhesive which is impervious to moisture, acid resistant and fusible upon the mere application of heat, i. e., without the use of a liquid. As the Examiner appreciates, the provision of this combination enables the production at a very high rate of speed of "center spot" caps in which the spots are accurately centered due to the absence of moisture from the adhesive. In other words, the use of heat alone in the punching and pressure applying operations effects the union of the heat softened or heat fused adhesive with the cork. There is no reference of record which suggests the production, as an article of manufacture, of either metallic foil or of paper of the character useful for the spotting of caps, either

provided with an adherent continuous coating of highly flexible adhesive which is impervious to moisture, acid resistant and fusible upon the mere application of heat. Applicant's discovery that this combination of elements facilitates and makes possible the provision of accurately centered spots overcame difficulties which prior to applicant's invention had made difficult the production of paper spot or of metallic spot caps on a commercial scale. While the invention is a simple one, it is, nevertheless, an extremely important contribution to the cap industry. This application, together with the companion application, Serial No. 414,614 disclose the invention in its entirety, the present case being limited to a species, to wit: adhesively coated foil, and the other application being limited to another species, namely, adhesively coated paper.

Although the Examiner has available patents which show the use of gutta percha as an adhesive, there is nothing suggestive in either of these patents of combining this adhesive with strip foil. While the Seiffert patent teaches the coating of metal foil broadly, this does not anticipate the invention. Applicant does not claim to be the first to apply adhesive to metallic foil even in the bottle cap art. It is the combination of the foil with the exposed continuous coating of adhesive of the type specified in the claims which is new with the applicant and which constitutes his contribution to the art. The claims recite the characteristics of the type, and since the combination is new, there is no basis for an aggregation of the individual or separate patents to anticipate them.

Allowance of this case is thought to be in order and is solicited.

Respectfully,

JJD:U

Attorneys.

WASHINGTON

February Two, 1933

Albin H. Werth, Assor.,

Your APPLICATION for a patent for an IMPROVEMENT in Bottle Cap Spot Material

filed Nov. 7, 1930 has been examined and ALLOWED with 2 claims.

The final fee, THIRTY DOLLARS, WITH $1 ADDITIONAL FOR EACH CLAIM ALLOWED IN EXCESS OF 20, must be paid not later than SIX MONTHS from the date of this present notice of allowance. If the final fee be not paid within that period, the patent will be withheld, but the application may be renewed within one year after the date of the original notice with a renewal fee of $30 and $1 additional for each claim in excess of 20.

The office delivers patents upon the day of their date, on which date their term begins to run. The preparation of the patent for final signing and sealing will require about four weeks, and such work will not be begun until after payment of the necessary final fee.

When the final fee is paid, there should also be sent, DISTINCTLY AND PLAINLY WRITTEN, the name of the INVENTOR, TITLE OF THE INVENTION, AND SERIAL NUMBER AS ABOVE GIVEN, DATE OF ALLOWANCE (which is the date of this circular), DATE OF FILING, and, if assigned, the NAMES OF THE ASSIGNEES.

If it is desired to have the patent issue to an ASSIGNEE OR ASSIGNEES, an assignment containing a REQUEST to that effect, together with the FEE for recording the same, must be filed in this office on or before the date of payment of the final fee.

After issue of the patent, uncertified copies of the drawings and specifications may be purchased at the price of TEN CENTS EACH. The money should accompany the order. Postage stamps will not be received.

The final fee will NOT be received from other than the applicant, his assignee or attorney, or a party in interest as shown by the records of the Patent Office.

NOTICE.—WHEN THE NUMBER OF CLAIMS ALLOWED IS IN EXCESS OF 20, NO SUM LESS THAN $30 PLUS $1 ADDITIONAL FOR EACH CLAIM IN EXCESS OF TWENTY CAN BE ACCEPTED AS THE FINAL FEE.

Respectfully,

Thomas E. Robertson
Commissioner of Patents.

February 1, 1934

Hon. Commissioner of Patents,

Washington, D. C.

Sir:

We hereby authorize and request entry of the following amendments in the above entitled application.

IN THE SPECIFICATION

Page 5

At the end of the page, after the amendatory matter now inserted add the following:

--A cap made from a material including an adhesive of the general character described has advantages which are not obtainable with the use of a gutta percha as an adhesive for uniting the center spot to the cushion disc. It has been found in the capping of beverages which are subjected to pasteurization that gutta percha tends to soften in the presence of wet or moist heat above 150°F., and the same applies to gutta percha containing compounds. A composition of the character described resists softening, not only through the temperature range of ordinary pasteurizing temperatures up to 150°F., but also through the range of forced pasteurizing temperatures which vary from 165°F. to 170°F. As a matter of fact, some liquids, such as vinegar, are pasteurized

through a range of 165 to 185°F., and I have found that, in my improved cap, the spot remains firmly united to the cushion disc up to 185°F. Furthermore, a gutta percha or gutta percha compound when used for uniting a center spot to a cushion disc, although having many advantages rendering it highly valuable in crown cap manufacture, has the tendency to swell in the presence of moisture. This swelling tendency becomes extremely pronounced under high pressures, such as are created within a bottle containing carbonated beverages, particularly when the latter are subjected to pasteurizing temperatures, e. g., in the pasteurizing of beer. The swelling of the adhesive uniting the center spot and the cushion disc separates and loosens the center spot and reduces the efficiency of the seal. In my improved cap, the adhesive layer or film uniting the center spot to the disc does not swell in the presence of moisture, and hence the spot does not separate from the cushion disc.

These characteristics are of vital importance in the manufacture of "center spot" caps; since the diameter of the spot or facing and of the adhesive layer uniting the same to the cushion disc is less than the cushion disc diameter, the capped liquid and the moist heat produced, e. g., during pasteurization, attack the adhesive layer around the periphery or edge of the center spot. Hence, the problem of maintaining an adherent union of the "center spot" with the cushion disc is not encountered in constructions wherein the facing is coextensive with and completely covers the cushion layer.--

---

IN THE CLAIMS

Add the following claim:

1713
1991

--4. As a new article of manufacture, highly flexible material in strip form for the spotting of cushion discs of caps with center spots of less diameter than the disc diameter consisting of a continuous layer of metallic foil coated on one side with a continuous exposed layer of waterproof, flexible, heat fusible and acid resistant adhesive adherent to the foil and adapted to adhere to a cork disc, said adhesive being substantially non-tacky at room temperature but fusible upon the mere application of heat and being substantially non-softening at temperatures up to and including 170°F. wet heat and being substantially non-swelling and non-contracting under conditions of moisture variation.--

REMARKS

The Examiner is, of course, aware of applicant's issued Patent No. 1,899,782, granted February 28, 1933, and which is hereby made of record. Said issued patent contains the generic claims to material of the type covered by the present application.

The new claim presented distinguishes from the issued patent for the reasons clearly set forth in the amendatory matter inserted in the present specification by this amendment.

The use of gutta percha or gutta percha compounds in this art is unquestionably a valuable contribution, particularly in connection with the "center spotting" of caps. That has been already recognized by the Patent Office and the tremendous commercial success of applicant's assignee in exploiting center spot caps in which the center spot facing is united by gutta percha adhesive to the cushion disc constitutes a corresponding recognition by the trade.

However, in the bottling of some liquids, it has been found advantageous, particularly for pasteurizing purposes, to use an

adhesive of the character disclosed in the present application; in other words, an adhesive which will not swell when subjected to moisture and heat above 150°F. Gutta percha tends to swell and softens under heat above 150°F.

The Examiner's attention is called to the distinguishing characteristics of the present invention which are set forth in the amendment to the specification, and these are embodied in the single new claim presented. The claim obviously distinguishes from the prior art and since it is not readable upon the disclosure of the issued patent (1,899,782) it is thought that the case may be allowed forthwith.

Respectfully,

Lothman Bryant Clarke & Lothman

REC'D

PETITION FOR RENEWAL

TO THE COMMISSIONER OF PATENTS:

Your Petitioner, Albin H. Warth, a citizen of the United States, and resident of Baltimore, State of Maryland, whose post office address is C/o Crown Cork & Seal Company, Inc., represents that on the 7th day of November, 1930, he filed an application for Letters Patent for an improvement in Bottle Cap Spot Material, Serial No. 494,201, which application was allowed February 2, 1933, but that he failed to make payment of the final fee within the time allowed by law. He now makes renewed application for Letters Patent for said invention, and prays that the original specification, oath and drawings, may be used as part of this application.

Applicant: Albin H. Warth

Ser. No. 494,201
Filed Nov. 7, 1930 Ren. 2-1-34
For Bottle Cap Spot Material

Claim 1 (original Claim 3) is directed to probably allowable subject matter.

New Claim 4 is rejected as being broader than the disclosure in view of the fact that applicant has described only one adhesive that possesses the properties recited. It is well established that the disclosure of only one substance does not give the right to lay claim generically to a whole class of substances. As is apparent, considerable experimentation would be required to determine just what compounds possess the attributes recited. In other words, the claim is so broad as to amount to nothing more than a mere hint for further experimentation. Line 5, "an" should be changed to -a continuous-

Sir:-

We hereby authorize and request entry of the following amendments in the above entitled application.

IN THE CLAIMS:-

Claim 4:
Line 3, strike out "an" and insert --a continuous--.
Same line, after "flexible" insert --, heat fusible--.
Add the following claims:-

--53. As a new article of manufacture, highly flexible material in strip form for the spotting of cushion discs of caps with center spots of less diameter than the disc diameter consisting of a continuous layer of metallic foil coated on one side with a continuous exposed layer of waterproof, flexible heat fusible and acid resistant adhesive containing a resinous material adherent to the foil and adapted to adhere to a cork disc, said adhesive being substantially non-tacky at room temperature but fusible upon the mere application of heat and being substantially non-softening at temperatures up to and including 170°F. wet heat and being substantially non-swelling and non-contracting under conditions of moisture variation.

1719

1997

4. As a new article of manufacture, highly flexible material in strip form for the spotting of cushion discs of caps with center spots of less diameter than the disc diameter consisting of a continuous layer of metallic foil coated on one side with a continuous exposed layer of waterproof, flexible heat fusible and acid resistant adhesive containing an adhesive resin adherent to the foil and adapted to adhere to a cork disc, said adhesive being substantially non-tacky at room temperature but fusible upon the mere application of heat and being substantially non-softening at temperatures up to and including 170°F. wet heat and being substantially non-swelling and non-contracting under conditions of moisture variation.

5. As a new article of manufacture, highly flexible material in strip form for the spotting of cushion discs of caps with center spots of less diameter than the disc diameter consisting of a continuous layer of metallic foil coated on one side with a continuous exposed layer of waterproof, flexible heat fusible and acid resistant adhesive containing a mixture of resins adherent to the foil and adapted to adhere to a cork disc, said adhesive being substantially non-tacky at room temperature but fusible upon the mere application of heat and being substantially non-softening at temperatures up to and including 170°F. wet heat and being substantially non-swelling and non-contracting under conditions of moisture variation.--

---

REMARKS

Reconsideration is respectfully asked of the rejection of claim 4. Applicant is a pioneer in the art of spot material and the present application has an effective date of 1927. Consequently, applicant is entitled to a very liberal interpretation of his invention and the scope thereof should not be restricted for purely formal reasons. -2-

The claim of record calls for strip material for the spotting of cushion discs or caps in the form of a continuous layer of metal foil coated with a continuous layer of (1) waterproof; (2) flexible; (3) heat fusible; and (4) acid resistant adhesive. In other words, the adhesive must conform to all of these qualifications and the claim is therefore limited specifically thereby and excludes various compositions or adhesives which do not have these properties.

In addition, the claim recites that the adhesive is (5) adherent to the metal foil and (6) adherent to a cork disc, both limitations restricting the field from which equivalent adhesives will be selected and further defining the adhesive.

The claim further recites (7) that the adhesive is substantially non-tacky at room temperature but (8) fusible upon the mere application of heat and (9) substantially non-softening at temperatures up to and including 170°F. These are more complete qualifications surrounding the adhesive and restrict the class of adhesives upon which applicant's discovery is based.

Furthermore, the claim recites (10) that the adhesive is substantially non-swelling and (11) none-contracting under conditions of moisture variation.

We feel that perhaps the Examiner has misunderstood the import of the claim and we hope that by listing the qualifications which are in effect limitations, that he will recede from his position. Applicant is attempting to cover broadly a class of adhesives which as a pioneer he is entitled to cover and the claim has been definitely limited to recite the qualifications and properties of the adhesive. Such being the case, it is felt that applicant is entitled to the claim since it is definitely limited to his discovery and excludes a large number of inoperative and undesirable adhesives which do not possess each and every one of the characteristics or limitations of the claim.

Claim 5 is similar to claim 4 but is even more restricted

by reciting that the adhesive contains a resinous material. Certainly this claim is patentable.

Claim 6 differs from claims 4 and 5 in reciting that the adhesive contains an adhesive resin. This claim is therefore even more definite and for the reasons above stated is clearly patentable.

Claim 7 recites that the adhesive contains a mixture of resins and it is thought that this claim will be found patentable.

In asking for reconsidération, we have in mind the position which this case occupies as a pioneer invention, and of course there is no prior art of record which even closely approaches the structure defined in the claims.

In view of all of these circumstances and to the further fact that the claims are definitely limited to applicant's construction of a strip spotting material, we ask the Examiner to carefully reconsider his action and to pass the case to issue.

Respectfully,

Attorneys for applicant.

WASHINGTON October Five, 1934

Albin H. Warth, Assor.,

Your APPLICATION for a patent for an IMPROVEMENT in Bottle Cap Spot Material
Renewed Feb. 1, 1934
Filed Nov. 7, 1930 has been examined and ALLOWED with 5 claims.

The FINAL fee, THIRTY DOLLARS, WITH $1 ADDITIONAL FOR EACH CLAIM ALLOWED IN EXCESS OF 20, must be paid not later than SIX MONTHS from the date of this present notice of allowance. If the final fee be not paid within that period, the patent will be withheld, but the application may be renewed within one year after the date of the original notice with a renewal fee of $30 and $1 additional for each claim in excess of 20.

The office delivers patents upon the day of their date, on which date their term begins to run. The preparation of the patent for final signing and sealing will require about four weeks, and such work will not be begun until after payment of the necessary final fee.

When the final fee is paid, there should also be sent, DISTINCTLY AND PLAINLY WRITTEN, the name of the INVENTOR, TITLE OF THE INVENTION, AND SERIAL NUMBER AS ABOVE GIVEN, DATE OF ALLOWANCE (which is the date of this circular), DATE OF FILING, and, if assigned, the NAMES OF THE ASSIGNEES.

If it is desired to have the patent issue to an ASSIGNEE OR ASSIGNEES, an assignment containing a REQUEST to that effect, together with the FEE for recording the same, must be filed in this office on or before the date of payment of the final fee.

After issue of the patent, uncertified copies of the drawings and specifications may be purchased at the price of TEN CENTS EACH. The money should accompany the order. Postage stamps will not be received.

The final fee will NOT be received from other than the applicant, his assignee or attorney, or a party in interest as shown by the records of the Patent Office.

NOTICE.—WHEN THE NUMBER OF CLAIMS ALLOWED IS IN EXCESS OF 20, NO SUM LESS THAN $30 PLUS $1 ADDITIONAL FOR EACH CLAIM IN EXCESS OF TWENTY CAN BE ACCEPTED AS THE FINAL FEE.

Washington, D. C.

Gentlemen:

Request has been made by Hauff and Warland for permission to obtain a copy of the application of Warth, No. 494,201.

The request is based upon the statement appearing in Warth's patent No. 1,967,195 that the application on which that patent issued is a division of application 494,201.

Action on this request will be withheld for one week from this date to give you the opportunity to state the objections, if any you have, to the request being approved.

Very truly yours,

R. F. Whitehead

MAIL ROOM AUG 21 1926 U.S. PATENT OFFICE

PETITION.

The Honorable Commissioner of Patents:

Your petitioner, Albin H. Warth a citizen of the United States, residing at Baltimore, ~~in the County~~ and State of Maryland (whose Post-Office address is c/o Crown Cork & Seal Co., 1511 Guilford Avenue, Baltimore, Md.) prays that Letters Patent of the United States be granted to him for the invention in BOTTLE CAPS

set forth in the annexed specification, and he hereby appoints Cleon J. Sawyer, James Q. Rice, James J. Kennedy and Philip B. Philipp (of the firm of Philipp, Sawyer, Rice & Kennedy, St. Paul Building, 220 Broadway, New York, P. O. Box 164, City Hall Station), his attorneys, with full power of substitution and revocation, to prosecute this application, to make alterations and amendments therein, to receive the Patent, and to transact all business in the Patent Office connected therewith.

Albin H. Warth

SPECIFICATION.

To all whom it may concern:

Be it known that I, Albin H. Warth a citizen of the United States, residing at Baltimore, ~~in the County~~ of ~~and~~ State of Maryland have invented certain new and useful improvements in

BOTTLE CAPS

fully described and represented in the following specification and the accompanying drawings forming a part of the same.

This invention relates to bottle caps.

Closures of the well known crown cork type comprise a metal shell having a corrugated skirt and a resilient sealing disk, usually of cork. When a bottle is to be sealed, a closure is applied with heavy pressure, e.g. 500-600 lbs., to effect a tight seal between the disk and the bottle, and the skirt is crimped around a locking shoulder on the bottle to secure the cap in place.

For use in packaging various materials, particularly certain mineral waters, cork disks have been provided with a facing of tin foil to protect the material from the cork or the cork from the material. This facing is ordinarily of a diameter less than that of the cork disk, the diameter being such that the tin foil partly but not entirely overlaps the rim of the bottle mouth. Such crowns are known in the trade as spot center crowns. An objection to these tin foil spot crowns is that the metal is apt to corrode under the action of certain liquids, such as alkalinated and acidulated liquids. Moreover, these crowns are relatively expensive.

It is an object of the present invention to provide a faced bottle cap suitable for sealing various materials, including alkalinated and acidulated liquids. It is a further object of the invention to provide a closure of the kind referred to that is capable of withstanding usual sealing pressures: that is capable of effecting a uniform sealing, with leakage, for high carbonated pressures; and that is relatively inexpensive.

With these general objects, and others not specifically mentioned, in view, the invention consists in the article which will first be described in connection with the accompanying drawing and then more particularly pointed out.

In the drawing:

Figure 1 is a sectional view, somewhat exaggerated for purposes of illustration, of a bottle cap embodying the invention; and,

Figure 2 is a similar view showing the cap applied to a bottle.

Referring to the drawing, the closure shown as an example comprises a metal shell 11 having the usual corrugated skirt 12. Within the skirt is a cork sealing disk 13, which may be of either natural cork or composition cork. The cork disk is faced with a so-called spot center 14, that is, a facing that is smaller in diameter than the cork disk but partly overlaps the bottle mouth when the closure is applied to a bottle. As appears in Fig. 2, when the closure is applied to a bottle 15, the spot center overlaps the bottle mouth sufficiently to cover the mouth and prevent any contact between the bottle contents and the cork disk. At the same time, there is some sealing contact between the cork disk and the bottle.

The spot center 14 of the present invention is non-metallic. It is characterized by toughness sufficient to avoid splitting at its edge under the sealing pressure exerted in applying the closure, usually about 600 lbs. It is further characterized by elasticity sufficient to make and mantain a seal without leakage for high carbonation pressures, e.g. 60-100 lbs. A suitable material is a tough and flexible paper coated with varnish, pitch or the like, for example, a varnished express paper. Such papers are made wholly or largely from a sulfite pulp as distinguished from kraft and other papers made from a sulfate pulp. Kraft papers, however, may be used if sufficiently tough and elastic.

While the spot center may be formed and assembled in various ways, this may be conveniently accomplished by

cutting disks of the proper diameter from varnished paper stock and in the best embodiments of the invention the stock will be between .005" and .015" in thickness. This paper disk is then secured to the cork disk by means of a backing 16 of some elastic and adhesive tissue, e.g. gutta percha, by means of a heated plunger or the like. By so applying heat and pressure to the assembled cork and paper disks the gutta percha or like backing is rendered adhesive and the paper spot is firmly cemented to the cork. In this connection, it is noted that apparatus for cutting and assembling spot centers is known in the art.

The resulting closure has a spot center that is practically tasteless, colorless and that does not corrode under the action of alkalinated and acidulated liquids, as in the case of tin foil and other metallic facings. The spot center is sufficiently tough to withstand sealing pressures without splitting or breaking and sufficiently flexible and elastic to maintain a seal for carbonation pressures as high as 100 lbs. per square inch. The gutta percha tissue being elastic tends to aid in the sealing effect and being insoluble in water tends to prevent the loosening of the spot in long contact with bottled contents.

WHAT IS CLAIMED IS:

872,273
1,145,024

1. A bottle cap of the crown cork type comprising a metal shell, a cork sealing disk and a non-metallic spot facing for the sealing disk.

2. A bottle cap of the crown cork type comprising a metal shell, a cork sealing disk and a paper spot facing for the sealing disk.

3. A bottle cap of the crown cork type comprising a metal shell, a cork sealing disk, and a spot facing for the sealing disk made of thin express paper characterized by toughness and elasticity.

4. A bottle cap of the crown cork type comprising a metal shell, a cork sealing disk, and a paper spot facing for the sealing disk secured to the latter by an elastic adhesive tissue.

1739

2017

In testimony whereof, I have hereunto set my hand.

Albin H. Warth

OATH

State of Maryland
City
~~County~~ of Baltimore } ss.:

Albin H. Warth the above-named petitioner, being duly sworn, deposes and says that he is a citizen of the United States, and resident of Baltimore, ~~County~~ ~~xxx~~, State of Maryland; that he verily believes himself to be the original, first, and sole inventor of the improvements in BOTTLE CAPS

described and claimed in the annexed specification; that he does not know and does not believe that the same was ever known or used before his invention or discovery thereof, or patented or described in any printed publication in any country before his invention or discovery thereof, or more than two years prior to this application, or in public use or on sale in the United States for more than two years prior to this application; that said invention has not been patented in any country foreign to the United States on an application filed by him or his legal representatives or assigns more than twelve months prior to this application; and that no application for patent on said improvements has been filed by him or his legal representatives or assigns in any country foreign to the United States.

Subscribed and sworn to before me this 10th day of August, 1926. } Albin H. Warth

BOTTLE CAPS,
Serial No. 130,631,
Filed August 21, 1926.

Div. 40 - Room 267

New York, May 18, 1927.

Hon. Commissioner of Patents,
Washington, D. C.

S i r :

In response to Official action of Nov. 30, 1926, reconsideration is requested.

The claims stand rejected for lack of novelty over Scott 872,153. It is submitted that there is nothing in Scott to suggest the closure defined. Scott merely mentions the use of a pasteboard liner in reconditioning caps. But applicant is not claiming such a liner broadly.

Claim 1 calls for a non-metallic spot facing. The facing of Scott is not a spot facing and with Scott's full facing of pasteboard it is practically impossible to effect a properly tight seal. Claim 2 is along the same lines. Claim 3 specifies a spot facing having certain characteristics not remotely suggested by Scott. Claim 4 calls for a specific cementing tissue not suggested in Scott.

An allowance is requested.

Respectfully submitted,

Albin H. Warth

Letter

PATENT OFFICE DEC 10 1927 DIVISION ART

New York, December 8, 1927.

Hon. Commissioner of Patents,
Washington, D. C.

S i r :

In response to Official action of June 23, 1927, reconsideration is requested.

Applicant has devised a cap having certain definite advantages as set forth in the specification. No such cap is suggested by the references.

Scott merely mentions the use of a pasteboard bushing in temporarily re-sealing partly emptied bottles. Such a thing could not suggest a paper spot, even though metal spots were known. It is a makeshift and not part of the cap and would be next to valueless under ordinary capping and carbonated pressures. Moreover, spot facings present certain problems that could not be solved by any suggestion in the Scott patent. Claim 3 is obviously not met by anything in the references and it is submitted that applicant is entitled to the broader claims in view of the fact that to find an anticipation Scott would have to be unwarrantably modified.

An allowance is requested.

Respectfully submitted,
Albin H. Warth

Filed August 21, 1926,	:	
BOTTLE CAPS	:	

New York, July 17, 1928

To the Commissioner of Patents,

SIR:

I hereby appeal to the Board of Appeals from the decison of the principal examiner rendered January 19, 1928 rejecting claims 1, 2, 3 and 4 in this application.

The specific grounds of error alleged are as follows:

1. The Examiner erred in rejecting claims 1, 2, 3 and 4 and each of them on the references and grounds stated.

2. The Examiner erred in not allowing each of claims 1, 2, 3 and 4.

An oral hearing is requested.

Paper No.6

Department of Commerce
U. S. Patent Office
Washington

MAILED
JUL 28 1928

In re: Application of
Albin H.Warth
Serial No.130[illegible]
Filed August 21,1926
Bottle Caps.

July 28,1928

Appeal to Board of Appeals

Examiner's Statement

This is an appeal on the following claims:

1. A bottle cap of the crown cork type comprising a metal shell, a cork sealing disk and a non-metallic spot facing for the sealing disk.
2. A bottle cap of the crown cork type comprising a metal shell, a cork sealing disk and a paper spot facing for the sealing disk.
3. A bottle cap of the crown cork type comprising a metal shell, a cork sealing disk, and a spot facing for the sealing disk made of thin express paper characterised by toughness and elasticity.
4. A bottle cap of the crown cork type comprising a metal shell, a cork sealing disk, and a paper spot facing for the sealing disk secured to the latter by an elastic adhesive tissue.

The references are:

(24)	Scott	872,188	Nov.26,1907	(215-39) and
(69)	Alberti	1,199,086	Sept.19,1915	(215-39)

The invention claimed consists of a bottle cap of the

crown cork type, comprising a metal shell, a cork sealing disk, and a paper spot facing secured to the disk by an elastic adhesive tissue.

Scott shows a metal cap of the crown cork type with a cork sealing disk therein covered with a small wafer or disk of pasteboard 10. See lines 104 and 105. Alberti shows a metal spot facing 15, Figure 3, stuck to the cork by an interposed cementing medium, albumen. See Page 2, lines 18 to 49.

The examiner holds that it would be merely mechanical skill to make the paper facing of Scott spot and to secure it to the sealing disk by an elastic adhesive tissue as this idea is disclosed at 15 and 16 Figure 4 of Alberti.

Respectfully,

M.f.

(BEFORE THE BOARD OF APPEALS)

B R I E F FOR A P P L I C A N T.

This is an appeal from a final rejection by the Principal Examiner of all the claims presented.

These claims are as follows:

1. A bottle cap of the crown cork type comprising a metal shell, a cork sealing disk and a non-metallic spot facing for the sealing disk.

2. A bottle cap of the crown cork type comprising a metal shell, a cork sealing disk and a paper spot facing for the sealing disk.

3. A bottle cap of the crown cork type comprising a metal shell, a cork sealing disk, and a spot facing for the sealing disk made of thin express paper characterized by toughness and elasticity.

4. A bottle cap of the crown cork type comprising a metal shell, a cork sealing disk, and a paper spot facing for the sealing disk secured to the latter by an elastic adhesive tissue.

The references are:

Alberti, 1,199,026

Scott, 872,153.

APPLICANT'S INVENTION.

The invention relates to closures of the well-known crown cork type. These closures ordinarily comprise a metal shell having a corrugated skirt which is crimped over a shoulder on the bottle, and a disk of cork or the like which makes sealing contact with the bottle mouth. Such a closure is shown in the drawing, in which 11 represents the metal shell with skirt 12, and 13 represents the cork disk.

While the crown cork, through its general use with mineral waters, sodas, drugs, etc., has come to be taken more or less for granted, the bottlers' problems still continue.

For many uses it is necessary to protect the bottled liquid from contact with the cork, and it has long been the custom, in bottling mineral waters and other liquids, to cover the cork with a facing of tinfoil. But the foil is liable to corrode under the action of certain liquids, such as alkalinated and acidulated liquids. Moreover, tinfoil is relatively expensive.

Applicant's problem was, in part, to produce a closure in which the bottled contents would be protected from contact with the cork and which would obviate the objections to tinfoil. His closure has a facing that is non-metallic, i.e., paper. But he is not claiming broadly the use of paper as a protective facing.

If a facing covers the entire surface of the cork various difficulties are met with. It is difficult to secure the facing in place, the sealing function of the cork is impaired, and the facing is apt to tear. In applicant's construction, the paper facing does not cover the entire surface of the cork sealing disk. As clearly ap-

pears in Fig.2 of the drawing, the facing 14 is small enough in diameter to permit some direct sealing contact between the cork and the lip of the bottle mouth. This direct contact is desirable for a proper seal. The facing, however, does extend far enough over the bottle lip to prevent contact between the cork and the bottled liquid. Thus, the facing performs its protective function without unduly impairing the sealing function of the cork disk.

A facing of this kind is known as a "spot" facing, and spot facings per se were not new with applicant. Tinfoil spots were known, as shown in the Alberti patent and as acknowledged in the specification.

But the solution of applicant's problem was not the simple substitution of a paper spot for the known tin foil spot. Crown corks are applied under high pressures, usually about 600 lbs. As stated in the specification, applicant's spot facing is characterized by toughness sufficient to avoid splitting at its edge under these high pressures. Moreover, certain liquids have a carbonation pressure of 60 to 100 lbs. Applicant's spot facing is further characterized by elasticity sufficient to make and maintain a seal without leakage for such carbonation pressures.

Such a closure is defined in claim 3 which calls for a spot facing made of "thin express paper characterized by toughness and elasticity."

THE REFERENCES.

The Examiner's position is apparently that there was no invention in making the "paper facing of Scott" a spot facing, in view of Alberti's tinfoil spot. In reaching this position, however, the Examiner has placed an unwarranted interpretation on the disclosure of Scott. The Scott patents shows a device for re-sealing bottles. That is, a

bottle may be opened, some of its contents drawn off, and the closure again affixed. The crown cork shown is a conventional crown cork without any facing. The disk of pasteboard 10, referred to by the Examiner, is a supplemental device. The Scott specification says (page 1, lines 99 et seq.) that if the cork disk is impaired when the bottle is opened, the disk or bushing 10 is put on in resealing to compensate. If one has a trunk that is wabbly, one reinforces it with a strap. But Scott's supplemental bushing is no more a part of the crown cork as an article of commerce than the strap is a part of the trunk.

There is, we submit, nothing in Scott's patent to suggest even remotely the use of a paper spot. No one, seeking to solve the problem of providing a closure for liquids for which a tinfoil spot was not suitable, could obtain any aid from a bushing such as that of Scott which is not part of the closure and is used only as an emergency makeshift.

Still less does Scott suggest the particular closure defined by claim 3. It is true that claims 1 and 2 do not include like limitations. But it is submitted that applicant, having been the first to produce a paper spot is entitled to claim it broadly.

Claim 4 recites that the paper spot is secured to the cork disk by an elastic adhesive tissue. As pointed out in the specification, this aids in obtaining a proper seal. Alberti refers to an adhesive and mentions albumen. Of course, adhesives per se were well known in all the arts. But there is nothing in Alberti's albumen adhesive to suggest applicant's elastic adhesive.

1756

2034

To sum up, applicant was the first to produce a crown cork having a non-metallic (e.g., paper spot); this closure contributed to the art distinct advantages not present in the old tinfoil spot crown; and this closure is not disclosed or suggested in the references.

It is submitted that the Examiner should be reversed and the claims allowed.

Respectfully,

Albert N. Marks

MAILED

RKH

IN THE UNITED STATES PATENT OFFICE

BEFORE THE BOARD OF APPEALS

Ex parte Albin H. Warth.

Application for Patent filed Aug. 21, 1926, Serial No. 130,631. Bottle Caps.

Messrs. Philipp, Sawyer, Rice & Kennedy for applicant.

This is an appeal from the action of the examiner finally rejecting claims 1 to 4, inclusive.

Claim 1 is representative and is as follows:-

1. A bottle cap of the crown cork type comprising a metal shell, a cork sealing disk and a non-metallic spot facing for the sealing disk.

The references relied upon are:-

Scott,	872,153,	Nov. 26, 1907.
Alberti,	1,199,026,	Sept. 19, 1916.

This application relates to a bottle cap of the conventional crown cork type to which a disk of tough paper has been secured to the inner wall of the cork by elastic cement. The purpose of the paper is to prevent the contact

1758

2036

of the liquid placed in the bottle with the cork.

The patent to Alberti discloses substantially the same arrangement except that tin foil is placed on the cap instead of paper. In both appellant's structure and that of Alberti the added disk does not extend to the outer edges of the cork and this, in both cases, is to permit the cork to engage the edge of the bottle where its sealing properties are effective. The patent to Scott discloses a bottle cap of the same character having a paper disk attached to the inner face of the cork; but in this case the disk is designed to be employed only with caps which have been used and have been somewhat deformed. The paper disk is intended to afford sufficient packing so that the cap may be reused. For this reason appellant contends that it does not teach the use of a supplemental disk in the manner disclosed by appellant and Alberti. While there is some force in appellant's contention, we do not consider that it would involve invention to substitute a paper disk for the tin foil disk of Alberti, especially as paper disks have been employed as shown by Scott, even though for a different purpose and extending to the outer edges of the cork. The use of elastic cement is, in our opinion, an obvious feature in attaching the disk.

The decision of the examiner is affirmed.

Interference No. 66,201

WARTH

vs.

JOHNSON

DISTRICT OF COLUMBIA, ss:

John J. Darby, being first duly sworn, deposes and says:

1. That he is a member of the firm of Cushman, Darby & Cushman, attorneys for Warth in the above entitled interference.

2. That deponent has been instructed by the assignee of the Warth application to file suit for patent infringement against Ferdinand Gutmann & Co. of Brooklyn, New York, and that one of the patents to be included in said suit is Reissue 19,117, Warth, March 20, 1934.

3. That deponent has personally observed the operations in the factory of Ferdinand Gutmann & Co., and believes the same to be a clear infringement of not only the four claims of said reissue patent, but also of each of the claims involved in the above entitled interference.

4. That the Warth application in interference is divisional with respect to the said Reissue patent 19,117, and that it is [fol. 2042] therefore desirable to include in the prospective suit the subject matter in interference, as well as the said reissue patent.

5. That if priority is awarded Warth in this interference, as deponent believes should be done, the patent resulting from the Warth application in interference will be included in said suit.

6. That the said Ferdinand Gutmann & Co., is, in deponent's judgment, infringing the rights of Warth's assignee under the said reissue patent, and that the said assignee is being seriously damaged by the use of the method covered by said patent, as well as use by the said Ferdinand Gutmann & Co., of the method involved in interference.

7. That deponent has been instructed by the assignee of the Warth application to expedite in every way possible the issuance of the patent on the Warth application in interference, and will do so not only throughout this interference, but in any subsequent ex. parte prosecution of the Warth application.

Further deponent sayeth not.

John J. Darby.

"Thanks! You're a Life Saver!"

Motorists everywhere are looking for cold tasty carbonated beverages. Keep yours popular by sealing satisfaction in every bottle with Armstrong's Crowns.

Thirsty motorists soon brighten up when a tray of cold, sparkling carbonated beverages appears on the scene. Ice can keep these soft drinks cold—but only good crowns can keep them sparkling.

MOTORIST, golfer, swimmer, hiker—and nearly everyone else these days—is looking for thirst-satisfying carbonated beverages. You are probably getting your share of this business. Make sure of keeping it all through the year, by capping every bottle that leaves your plant with a tight-fitting Armstrong's Crown.

There is no lost flavor, no disappointed customers when Armstrong's Crowns are used. For more than seventy years Armstrong's have been Cork Headquarters. During this time they have processed cork through every step in its manufacture from tree to finished product. Their reputation for faithful service established over this period is your complete assurance that every Armstrong's Crown is *right*.

Conveniently located branch offices assure prompt deliveries on all orders, large or small. Address your order to the nearest branch office, or write directly to the Armstrong Cork Company, Cork Division, Crown Cap Section, Lancaster, Pennsylvania.

[fols. 2046-2047] IN UNITED STATES DISTRICT COURT, EASTERN DISTRICT OF NEW YORK

Equity No. 7371

CROWN CORK & SEAL COMPANY, INC., Plaintiff,

against

FERDINAND GUTMANN & Co., Defendant

March 2, 1936.

Gifford, Scull & Burgess, Solicitors for Plaintiff; George F. Scull and John J. Darby, of Counsel.

Hauff & Warland, Solicitors for Defendant; William E. Warland, Francis H. Warland, and N. L. Leek, of Counsel.

OPINION, CAMPBELL, D. J.

This is an action in equity in which plaintiff seeks relief by injunction and damages for the alleged infringement of the six following patents, for center spot crowns for bottles, and methods of making such spot crowns, to wit:

(1) Patent No. 1,339,066, issued to Charles E. McManus, for Bottle-Closure, dated May 4, 1920, on an application filed November 17, 1915; (2) Patent No. 1,899,782, issued to Albin H. Warth, assignor to Crown Cork & Seal Company, Inc., for Material for Facing Bottle Caps and Method [fol. 2048] of Making Same, dated February 28, 1933, on an application filed December 17, 1929; (3) Patent No. 1,899,783, issued to Albin H. Warth, assignor to Crown Cork & Seal Company, Inc., for Bottle Cap and Method of Manufacturing Same, dated February 28, 1933, on an application filed May 5, 1929, divided and this application filed October 31, 1930; (4) Reissue Patent No. 19,117, issued to Albin H. Warth, assignor, by mesne assignments, to Crown Cork & Seal Company, Inc., for Process of Producing Closures, dated March 20, 1934. Original No. 1,788,260, dated January 6, 1931, Serial No. 159,743, January 7, 1927. Application for reissue January 23, 1934; (5) Patent No. 1,956,481, issued to Albin H. Warth, assignor to Crown Cork & Seal Company, Inc., for Spot Crown and Liner Material Therefor, dated April 24, 1934, on an application filed June 16, 1933; (6) Patent No. 1,967,195, issued to Albin H. Warth, assignor to Crown Cork & Seal Company, Inc.,

for Method of Manufacturing Bottle Caps, dated July 17, 1934, on Original Application November 7, 1930, Serial No. 494,201, which in turn is a division of Serial No. 159,743, January 7, 1927, now Patent No. 1,788,260, dated January 6, 1931. Divided and this application filed April 4, 1933.

The general defenses of the defendant are, invalidity of all of the patents over the prior art, laches and estoppel on the part of the plaintiff as to one of the patents, non-infringement, lack of title to two of the patents in suit, owing to collusion in interference proceedings in the Patent Office, in which interference priority was purported to have been found in favor of the patentee Warth, prior use by the defendant and others as to some of the patents, prior use [fol. 2049] by the plaintiff as to some of the patents, the plaintiff has not come into Equity with clean hands, for the reason that it has suppressed evidence in the Patent Office in some of the interferences and applications, and also attempted to suppress evidence of other material facts. Defendant has also counterclaimed against the plaintiff alleging infringement of Patent No. 1,921,808, issued to Benno Cohn, assignor to Ferdinand Gutmann & Co., for Method of Making Closures, dated August 8, 1933, on an application filed July 20, 1932, the title to which patent is now in the defendant.

The plaintiff is a New York corporation with its principal factory at Baltimore, Maryland.

The defendant is a New York corporation with its factory in Brooklyn, New York.

Plaintiff's title to all of the said patents, except McManus No. 1,399,066 is stipulated.

As to the McManus Patent No. 1,399,066 plaintiff is the owner, and takes its title in the following manner:

Plaintiff was formed by a consolidation of New Process Cork Company and New York Improved Patents Corporation, each a corporation of the State of New York. The McManus patent in suit was assigned by McManus, to whom the patent issued to Cem Securities Corporation, which corporation granted an exclusive license under that as well as other patents to New Process Cork Company. The Cem Securities Corporation assigned the entire right, title and interest of the McManus patent in suit, together with other patents, to the plaintiff. No formal instrument transferring to plaintiff the exclusive license granted to the New Process [fol. 2050] Cork Company was shown, but since the New

BLANK

PAGE

BLANK

PAGE

Process Cork Company was one of the merging companies from which plaintiff was formed, obviously the exclusive license was thus carried to plaintiff, thus vesting in plaintiff both the legal title and any outstanding exclusive license.

The crown cap to which the center spot of the patents in suit is applied, has a thin metal shell with corrugated skirts, adapted to be pressed into engagement with a lip on the bottle, to hold the cap tightly in place. Inside the cap is a disc of cork, either natural cork or composition cork, the latter being made up of small particles held together by a binder. Without something on the disc, the liquid contents of the bottle come directly into contact with the cork disc. This has created a problem as to certain beverages, which has been solved by the center spots.

The desirability of covering the cork closure with some material which would prevent contact between the beverage and the cork was appreciated by the art for a long time. Where the bottle contents are not under gas pressure, this can be done by the "overall" form of closure, in which a sheet of paper or foil covers the entire surface of the cushion disc, but as this interposes the paper or foil between the entire bottle neck and the cushion disc, it is not suitable for pressure beverages. The cushion discs in such overall crowns are cut out of a composite sheet of cork or pulp board, which has previously been faced with the facing material.

For high pressure beverages which are to be held for a long time without leaking or breaking down, the center spot is designed, and it is particularly desirable for bever- [fol. 2051] ages having a national distribution from one or more bottling points, and to enable the use of relatively cheap composition cork discs. The facing material is applied to the cork disc, so that the cork can still function as a seal against the mouth of the bottle while, at the same time, the periphery of the center spot is also engaged by the neck of the bottle to prevent, so far as possible, the liquid in the bottle from reaching the cork disc of the closure.

The center spot crown illustrated on Exhibit 17 may be of paper or metal foil, and is large enough to extend part way over the lip of the bottle mouth, leaving a considerable area of the lip to be contacted by the cork disc itself which forms the pressure holding seal, while the center spot

keeps the beverage from contacting with the cork. Before being applied to the bottle, the center spot lies flat on the surface of the cork, but when the crown is placed on the bottle under very heavy pressure, the cork adjacent to the periphery of the shell is highly compressed, resulting in a deformation of the center spot, which subjects the center spot to a considerable stretching pressure, and the spot material must be strong enough to withstand it.

It is essential for pressure beverages that the spot be accurately centered on the cork disc. If it is not, a part of the center spot may extend over the entire surface of the neck of the bottle at one side, and thus permit leaking and, at the other side, it would be pulled away from the neck of the bottle, and thus permit the bottle contents to contact with the cork.

To prevent complaints as to the results of the bottling, either on the part of the bottler or consumer, the center [fol. 2052] spot crowns must be substantially perfect as the caps are applied to the bottles at a rate of speed as high as 160 a minute, and the bottler has no time to inspect each center spot crown to make sure that it is satisfactory.

Both to stand shipment and because of the conditions obtaining in the bottle capping machine itself, it is essential that the spots be very tightly affixed to the di-cs.

To meet the competition with other forms of corking, the spot crowns must be made cheaply, and to do this the spots must be accurately and positively placed in position, at a high rate of speed, and with a minimum number of "rejects" requiring subsequent operations.

A tremendous amount of spot crowns are made and sold today, at from 22 to 24 cents a gross, which includes the entire crown, consisting of the shell with its ornamental printing, the composition cork disc, and the center spot.

By the methods of the patents in suit, plaintiff is now applying these spots to crowns at the rate of 500 per minute for each operating unit, and its sales at the annual rate of about 9,000,000 gross of center spot crowns constituting about 30% of its entire crown production.

Plaintiff has some 15 licensees under the patents in suit, who are also producing center spot crowns, and adding defendant's output, the total annual output of center spot crowns is of very large proportions.

The first patent in suit is the McManus patent No. 1,339,066, of which claims 3 and 8, reading as follows, are in suit:

[fol. 2053] Claim 3:

"3. A bottle closure embodying therein a metallic cap, a compressible disc within said cap, and a flexible disc of non-absorbent material superimposed upon and united by means of a fusible binding medium with, said compressible disc, said superimposed disc being of smaller diameter than said compressible disc, whereby a sufficient portion of the surface of said compressible disc is exposed, to permit the sealing of the bottle directly against said compressible disc and the portion of the compressible disc within the neck of the bottle is protected by said flexible disc."

Claim 8:

"8. A bottle closure embodying therein a metallic cap, a compressible disc secured within said cap by means of a fusible binding medium, and a flexible disc of non-absorbent material superimposed upon, and united by means of a fusible binding medium with, said compressible disc, said superimposed disc being of smaller diameter than said compressible disc, whereby a sufficient portion of the surface of said compressible disc is exposed to permit the sealing of the bottle directly against said compressible disc and the portion of the compressible disc within the neck of the bottle is protected by said flexible disc."

This patent describes the center spot substantially as I have hereinbefore described it.

The patentee in his specification showed his knowledge [fol. 2054] of what is required in a center spot, and disclosed various ways to make such a center spot.

At page 2, commencing at line 75 of the patent, McManus describes the attachment of the flexible disc (center spot) to the compressible disc (cork disc), either by the binding medium used to bind the granules of the composition disc, or by the kind of binding medium used to hold the disc to the cap shell.

At the time of the filing of the application, the material used to hold the disc in the cap was a gum and resin combination. This was a thermoplastic cement; that is, one

which becomes tacky when heated so that, when it is pressed into contact with a surface, it will adhere thereto when the cement cools.

At page 2, lines 81-84, McManus says: "By using this bond, the disc e and the disc f may be assembled in relation to the cap and to each other by one and the same operation if desired."

With the exception of the so-called "White Rock" center spot, there is universally used, as the adhesive for attaching the center spot, a heat fusible, one such as gutta percha or a thermoplastic nitrocellulose-resin combination, which is one of the elements of the claims 3 and 8 in suit. The fusible binding medium has displaced the water soluble adhesives and the heat-set adhesives, the use of which was previously attempted by others in what proved to be commercial failures.

Center spot caps adhered by a heat-fusible cement were not commercialized by McManus because the particular thermoplastic used by him, consisting of copal and rosin, [fol. 2055] with a little wax to soften it, was rather brittle, and he attempted in his commercial production to use a water soluble adhesive, but the limitations of this adhesive in his commercial production rendered it unsuccessful.

The fact still remains that McManus was the first to perceive and disclose to the world the use of a heat-fusible cement, to stick the center spot to the cork, and it is immaterial that neither the plaintiff nor defendant uses the particular kind of thermoplastic bond that McManus gave as an illustration. duPont v. Glidden, 67 Fed. (2d) 392, 393.

The defendant has offered in evidence as the alleged prior art thirteen patents, the showing of which was not explained on the trial, but they have been discussed by the counsel for the respective parties in their briefs, and I will briefly consider the same.

French Patent No. 415,794, to Societe American Cork & Seal Company, published October 4, 1910, shows the so-called "American" form of a crown illustrated on chart 17, in which the cushion was a rubber ring and the center member analogous to a center spot, was a cup-shaped piece of foil with the cup extending over the ring to hold the latter in place. The spot was not adhered to the cushion disc but was soldered to the metal shell where the two metals were in contact, and solder obviously would not be useful in adhering a spot to a cork disc.

French Patent No. 463,971, to Montaner & Co., published March 10, 1914, shows a plain tin center spot on a cork disc, which is to be fastened to the cork by being "stamped or pasted," without further suggestion as to how this "stamp-[fol. 2056] ing" or "pasting" is to be done, and, in particular, what kind of "paste" is to be used.

British Patent No. 16,075, A. D. 1913, to Ernest Frederic Edouard DeMuth, accepted July 9, 1914, shows a metal foil center spot adhered to the cushion disc "by cementing or in any other appropriate manner." There is no suggestion as to how this cementing is to be done, or what kind of cement is to be used.

British Patent No. 26,297, A. D. 1909, to John MacCormack and David Eglin McPhun, accepted November 10, 1910, shows a disc A of wood pulp, the drawing showing the wood pulp disc contacting with the bottle top, but with the tinfoil disc B no larger than the interior of the neck of the bottle. Such a construction experience has shown to be wholly inoperative. The patent also contains the general statement, that the tinfoil is to be coated with some "adhesive substance," without any specification of the kind of adhesive to be used.

Patent No. 1,199,026, to John Alberti, granted September 19, 1916, shows a bottle-closure with a center spot crown. This is the nearest reference to the patent in suit. It taught the use of a wet-heat-set adhesive (albumen), which is not now in use, but did not even suggest the use of a thermoplastic to adhere the spot to the cork. The heat-set adhesive of Alberti was the reverse of the heat-fusible adhesive of the patent in suit, which latter adhesive has proved to be the solution as is shown by its present day universal use. The sample center spot crowns made by Alberti, produced from the files of the Patent Office, which were filed in connection with his application for patent, do not prove that the wet-[fol. 2057] heat-set crowns were commercially practical, because as Alberti says, they were made partially by hand, which, done slowly and carefully, can be accomplished with almost any kind of adhesive.

Patent No. 903,865, to John A. Jones, granted November 17, 1908, shows a method for making composition cork discs by the use of a solution of pure rubber. It discloses no center spot.

Patent No. 1,110,138, to John A. Jones, granted September 8, 1914, shows an ordinary crown cap in which a cork

composition is held in the shell. It discloses no center spot nor any kind of covering for the disc.

Patent No. 993,288, to Leonard Bartlett, granted May 23, 1911, shows a machine for making a crown of the type which uses a ring instead of a disc, and leaves no resilient member in the center. In the center of the crown metal foil was used which was cupped and flanged so that the center could be adhered to the crown, and the flanges could be used to hold the rubber ring in place. The rubber ring took the place of the cork but was not itself adhered to the metal shell. The so-called center spot was used as a means to hold the rubber ring in the shell and at the same time protect the rubber ring from the contents of the bottle. The so-called center spot was held to the shell by solder.

Patent No. 1,195,392, to George M. C. Nielsen, granted August 22, 1916, shows an elaborate machine for the manufacture of the so-called, "White Rock" or "Stewart" center spot crown, and in Figs. 13 and 15 the crown itself. The spot is a circular piece of metal foil, having its edges turned up to form a cup, and the edges inserted into a circular slit cut in the cork, thus holding the spot mechani- [fol. 2058] cally and not adhesively to the cork. The necessity for using in this type of spot crown natural cork and not a composition cork disc adds greatly to the expense, and prevents general competition with the crowns of the patent in suit. As the spot must be of metal foil, and cannot be of paper, its field is restricted as metal foils cannot be used with acidulated beverages, like dry ginger ale. It is used substantially by one company only.

This was the only commercial spot crown prior to that of the McManus patent in suit, and has been used by the White Rock Company since 1914.

Patent No. 1,129,578, to George F. Knox, granted February 23, 1915, shows a better seal for the ordinary crown cap, to accomplish which the patentee proposed having the bottles specially made with a circular groove in the top into which the cork would be pressed. He also provides a pliable facing sheet, which may be of tinfoil and is of a diameter approaching that of the cork disc. He expects the swelling of the cork to break the spot when applied to his specially shaped bottle top. Fig. 3 shows a special form in which there are a series of perforations to hasten this breaking. No reference is made to any adhesion of the

covering to the cork, and none is needed because he has lapped the covering material around the edges of the cork disc, as shown in Fig. 2.

Patent No. 408,177, to Daniel W. Johnson, granted July 30, 1889; Patent No. 957,064, to Charles R. Keeran, granted May 3, 1910; and Patent No. 796,356, to Frederick Recht, granted August 1, 1905, all of these three patents being [fol. 2059] referred to only as showing the state of the art. Each of these patents shows a cap of an overall form, the cushion disc of which has its entire face covered with the protecting material which, rather than the cushion disc itself, really forms the seal. This cap is not satisfactory for pressure bottling. No adhesive is mentioned, the obvious intent being that the protecting material shall be merely laid on the surface of the cushion disc. Reference is made to "wax," but it is to be used to seal the protecting disc to the mouth of the jar rather than to the cushion disc. No center spots are shown in any of the patents. None of the patents of the prior art anticipates the patent in suit.

From all the evidence it seems quite clear to me that neither gutta percha nor any thermoplastic or heat-fusible adhesive was used by the plaintiff or any one prior to 1917, and this is not overcome by the testimony of Smith in the interference proceeding, given entirely from recollection, and as to date given by him, about 1914, he then said, "I am not sure what it was in 1914."

From my examination of the prior art, it appears that what McManus did was much greater than a mere change of the adhesive, in fact it was the solving of a real problem which practical men in the art had tried and failed to solve, and the turning of failure to success by means not even suggested by the prior art.

This, I believe, constituted invention and the McManus patent in suit is valid.

I do not agree with the defendant's contention that the McManus patent is limited to parchment paper. Foil was, at the time of the filing of the McManus application a well [fol. 2060] known equivalent for paper in the manufacture of spot caps of other construction and while claim 2 of the patent in suit limits the spot to papers, claims 3 and 8, which are here in suit, are not so limited but require a disc of non-absorbent material.

In claim 3 of the patent in suit, a center spot crown is de-

scribed, the novel feature of which is a fusible binding medium for adhering the spot to the cork disc, and in claim 8 there is described a center spot crown in which a fusible binding medium is used to hold the spot to the disc, and to hold the disc in the shell of the crown.

The stipulated crowns, representative of those made by the defendant, Exhibits 6, 7 and 8, use gutta percha to adhere the spot to the cork disc, and this is heat-fusible. In defendant's caps, Exhibits 4 and 5, an adhesive known as #4620 duPont is used, which is also heat-fusible. These caps infringe claim 3 of the McManus patent in suit.

In defendant's caps, Exhibits 4 and 8, the disc is attached to the shell by a fusible binding medium, and infringe claim 8 of the McManus patent in suit.

In 1927, the patentee McManus acquired control of the plaintiff, of which the Crown Cork & Seal Company was a predecessor, and defendant contends that because there is nothing to show that McManus sued the Crown Cork & Seal Company for its infringement of his patent, plaintiff is guilty of such laches against defendant that neither an injunction nor any accounting should be granted. This contention is not sustained except for its abandoned experiment of January, 1925, defendant did not manufacture [fol: 2061] an infringing crown until late in 1928. McManus was engaged in litigation with the International Cork Co. until 1926, when he acquired it. McManus had been a stockholder in the Crown Cork & Seal Company from 1922, during which time he had been endeavoring to acquire control of the company.

It does not seem to me that defendant can justify its infringement which commenced years later by the fact that McManus merged his company with Crown Cork & Seal Company instead of indulging in expensive litigation with it while he was engaged in patent litigation with another company. There is no evidence that defendant was misled by the conduct of McManus.

There is no evidence that it came to the attention of McManus that the other companies mentioned by plantiff's witnesses were infringing, or its extent, but in any event, most of the companies mentioned accepted licenses under the McManus and other patents, as soon as the patent was called to their attention, and are paying royalties today.

The cases of Dwight & Lloyd Sintering Co. v. Greenawalt, 27 Fed. (2d) 823; Banker v. Ford Motor Co., 69 Fed. (2d)

665; and Westinghouse Electric & Mfg. Co. v. Jeffrey-DeWitt Insulator Co., 22 Fed. (2d) 277, are clearly distinguishable, as in none of them was it contended that there was any question of laches raised, because of the relationship of the plaintiff to other infringers than defendant.

The defendant also contends that the plaintiff is estopped from maintaining any suit against it based upon certain correspondence between the parties, and the assertion that [fol. 2062] plaintiff knew, in 1928, of defendant's infringement. This contention is not sustained. I find no reference in either letter as to patents, nor do I find any evidence to support defendant's assertion that plaintiff knew of defendant's infringement in 1928. The offer of plaintiff to sell to defendant, like other crown manufacturers, various kinds of cork discs, does not show any knowledg-ment of the fact of defendant's infringement or its extent. The letter of 1930 did not induce defendant to undertake the manufacture of infringing crowns for Goetz, whom it had been selling since 1928, or for any one else.

While I well understand that each case involving the defense of laches and estoppel, must be decided on its own facts, it seems to me that applying the general rules laid down in Benthall v. National, 222 Fed. 918, 922; Simpson v. Newport, 18 Fed. (2d) 318; Mills vs. Monarch, 49 Fed. (2d) 28, 30; and Walker on Patents, 6th Ed. Vol. 1, p. 726, cited by plaintiff, the defendant cannot succeed in that defense.

There is no proof in the case at bar that defendant, to its disadvantage, relied upon any act or lack of action of the plaintiff, or that defendant, during the period in question, changed its position, or that its actions were based upon an assumption that plaintiff did not intend to enforce its patent rights. It is not shown that plaintiff had knowledge of defendant's infringement prior to 1933.

The McManus patent No. 1,339,066, as to the claims in suit, is valid and infringed.

The second patent in suit is the Warth patent No. 1,899,782, of which claims 7 and 9, reading as follows, are in suit:

[fol. 2063] Claim 7:

"7. As a new article of manufacture, laminated bottle cap spotting material in strip form comprising hard, tough

paper having relatively low absorptive properties, a coating of resistant varnish on one surface of the paper and bonded to the other surface a coating of gutta percha."

Claim 9:

"9. As a new article of manufacture, highly flexible material in sheet or strip form for the spotting of cushion discs of caps with center spots of less diameter than the disc diameter consisting of a continuous layer of metallic foil coated on one side with an exposed continuous layer of waterproof, flexible, and acid resistant adhesive adherent to the foil and adapted to adhere to a cork disc, said adhesive being substantially non-tacky at room temperature, but fusible upon the application of heat and substantially impervious to moisture whereby spots may be punched from the strip and united to the cushion discs of caps by the mere application of heat and pressure."

Claim 7 is limited to a laminated bottle cap spotting material of hard, tough paper in strip form, with a coating of resistant varnish on one surface, and a coating of gutta percha on the other. Claim 9 is for a strip of bottle cap spotting material consisting of a metal foil coated on one side with a thermoplastic adhesive.

[fol. 2064] The claims in suit are for the strip as a new article of manufacture, and not for the machine or method of manufacture.

Briefly described, the patent shows a strip of paper, or other material, drawn between a series of rollers, and thereby one side of the material is coated with a coat of gutta percha. This gutta percha material is fed through a cap-assembling machine, and spots of the size required for center spot crowns are punched from this material, and the gutta percha center spots are secured to the cork lining of a cap by means of heat and pressure, causing the gutta percha to adhere to the cork or composition cork lining.

The plaintiff uses these strips in connection with the Wårth method of the patents in suit, to make paper spots and metal foil spots, respectively.

The defendant has offered in evidence as the alleged prior art, which were not explained on the trial but were discussed by the counsel for the respective parties in their briefs, the following patents:

Patent No. 1,213,926 to Charles E. McManus, granted January 30, 1917, a strip of tinfoil having a layer of paper, the exposed side of which was "gummed," and the other side bonded to the metal foil by some binding medium such as sodium silicate. The spotting strip of McManus was formed of two layers of material bonded to each other, the face of the paper being covered with a water-soluble adhesive, the gum being described as permitting the application of the material of the strip to a cork by dampening the cork itself.

Patent No. 1,638,541, to Charles E. McManus, shows a [fol. 2065] strip material to be used for "overall" discs to be placed in metal shells. The strip is made up of a layer of rubber to which is adhered a layer of paper having a cement binder to which another layer of paper is adhered. Discs are cut from this composite strip to be used instead of cork discs for bottle closures. This is not center spot material.

Patent No. 1,657,802, to Louvern G. Lange, granted January 31, 1928, shows a sheet of paper with one face coated with a water-soluble gum, and the other side coated with a quick-drying oil varnish. The cement of the sheet having been dried, it is run through water to wet the adhesive, and the dampened sheet is then pressed into contact with the pulp board to form a composite sheet from which the desired discs can be cut simultaneously across the entire width of the composite sheet. Discs for shells for jars for preserves, mayonnaise, mustard and the like can be punched from the composite strip material.

Patent No. 1,758,610, to Louvern G. Lange, granted May 13, 1930, contained but a single claim, which was granted to Warth as a result of interference No. 60,878, and is now claim 3 of the Warth patent in suit, No. 1,899,782.

In 1927, Warth built a combining machine by which strips of spotting material could have a thermoplastic adhesive combined with it, and had used the machine for combining metal foil with gutta-percha. The combined strip was first used in making the experimental lots of Warth paper spot crowns sent to Burroughs Bros., in April, 1927, and Macomber, in August, 1927. Lange's earliest date is his filing date of July 3, 1929.

Patent No. 983,319, to Smith, granted February 7, 1911, [fol. 2066] shows an overall type of closure, the sealing

pad of which has a sheet of Manila paper adhered to it, which paper is coated with a layer of cellulose varnish, and adhered to the pad by a water-soluble glue but not a thermoplastic.

Patent No. 1,238,156, to Reinhold Gustav Koch, granted August 28, 1917, shows an overall covering for a cork pad, the metal foil layer F being adhered to a paper covering by the vulcanized rubber E, the paper D, which is tough but absorbent, being adhered to the face of the cork a by the gutta percha C, and the cork a being adhered to the shell or cap A by a mixture of tartaric acid gum arabic and rosin, which by the application of heat sticks the cork disc to the cap.

Patent No. 1,358,834, to Frederick W. Farrell, granted November 16, 1920, shows a strip of paper coated with Trinidad asphalt, adapted to be used for sealing cartons.

Patent No. 408,177, to Daniel W. Johnson, granted July 30, 1889, which is referred to only as showing the state of the art, shows an overall sealing gasket in which a layer of parchment or parchmentized fiber is secured to a felted body by cement, the kind not being mentioned.

Patent No. 957,064, to Charles R. Keeran, granted May 3, 1910, which is referred to only as showing the state of the art, shows an overall closure with a cushion of pulp board, over which is a layer of blotting paper saturated with sealing wax, rubber, or the like, and below that a disc of oil paper which does not overlap the bottle lip.

The prior art shows that many inventors had the idea of [fol. 2067] a spotting material coated in some manner with an adhesive.

It is true that none of them had the exact combination of Warth, but the use of paper or metal for spots, with gutta percha as the adhesive, although not coated on the same strip, was known and had been in use by plaintiff as early as 1917.

McManus, as early as November 17, 1915, the filing date of his patent in suit No. 1,339,066, had disclosed the use of a fusible binding material in the place of a water-soluble adhesive or a heat-set adhesive, and it does not seem to me that with this teaching and the knowledge that was possessed by the art, there was any invention in selecting gutta percha or duPont 4620 as an adhesive, and coating the strip therewith, but that it was a mere substitution of material, made when it became desirable to put into use

commercially the McManus cap, using the fusible binding material. This finding renders unnecessary any extended consideration of the questions raised by the defendant as to filing dates and the Lange interference proceeding, and also as to whether the defendant has established its defense of prior use in 1925; but in any event, it was established that defendant, in 1925, manufactured about 300,000 center spot crowns for the Inecto Company, using for the material from which the center spot was cut strips on which gutta percha and tinfoil were mounted together; and although the defendant abandoned its experiment, and whether it can be or cannot be considered as an anticipation, as to the spotting strip alone, it does show that the use of gutta percha and metal for spotting strips was known to the art.

[fol. 2068] The claims in suit of the Warth patent No. 1,899,782 do not show novelty or invention and are invalid.

The third patent in suit is Warth patent No. 1,899,783, of which claim 4, reading as follows, is the only one in issue:

Claim 4:

"4. A bottle closure comprising a metallic shell, a cushion disc in said shell, a facing disc of hard, high-gloss paper having a varnished outer surface, said disc being of smaller diameter than and concentric with said cushion disc, and a stratum of gutta percha co-extensive in area with the facing disc between the latter and the cushion disc and adhesively uniting the two discs."

This patent relates to bottle caps and the method of manufacturing the same, but claim 4 in suit relates only to the bottle cap and not to the method.

In his specification Warth describes at length what had preceded it, and then what he has done to overcome the difficulties.

He describes as the center spot material he uses (commencing p. 3, l. 33) a tough paper having a hard or high-gloss finish, for example such as termed a water-finish "which will not fracture, has an inherent resistance to liquids and gases, and serves as an excellent carrier for an exposed or outer facing of varnish and for a backing layer of water insoluble, heat-fusible, and acid and gas-resistant adhesive."

For his hard high-gloss paper he recommends "express [fol. 2069] paper, sulphite paper or bleached kraft paper having a water-finish, i. e., high-gloss finish" (p. 3, l. 75).

He uses a varnish which consists of "resin, China-wood oil and a drier, and containing a plasticizer (p. 4, l. 113), and for his adhesive gutta percha (p. 3, l. 111).

Warth says he began his investigation which led to this patent in suit in 1920, and that he did considerable experimenting.

The defendant offered in evidence the following alleged prior art, the showing of which was not explained on the trial, but they have been discussed by counsel for the respective parties in their briefs, and I will briefly consider the same.

Patent No. 1,339,066, to Charles E. McManus, granted May 4, 1920, which is here in suit, shows the use of a fusible binding medium in a center spot cap with a disc, "made of a hard parchment paper, or of any other paper so treated as to make it non-absorbent."

Patent No. 983,319, to Eugene C. Smith and Victor E. Smith, granted February 7, 1911, shows an overall seal in which a piece of Manila paper 3, was held to the pad by a water-soluble adhesive made up of glue, glycerine and sugar, with the outer coating of Manila paper covered with a celluloid varnish.

Patent No. 1,238,156, to Reinhold Gustav Koch, granted August 28, 1917, shows an "overall" covering for a cork disc, the material next to the bottle contents being the metal foil F. The foil is adhered to a sheet of paper by vulcanized rubber and the paper, in turn, is held to the cork by gutta percha.

[fol. 2070]. Patent No. 1,215,737, to George Emil Stahl, granted February 13, 1917, shows an overall closure. Next to the beverage was tissue paper, which was held to a jute stock paper layer by gutta percha with a couple of layers above it. It does not seem to me that this cap could be used for beer as Stahl thought, because its overall character would prevent it from holding high pressure beverages, and the tissue paper, if used for acidulated beverages, would be readily penetrated by the moisture.

Patent No. 1,779,884, to Louvern G. Lange, granted October 28, 1930. This patent does not show a paper spot crown of the Warth construction, and is not prior art to this patent in suit.

Patent No. 671,191, to Edward W. Hanauer, granted April 2, 1901, shows the use of gutta percha to fasten the turned-up bottom of trousers to the trousers leg.

Patent No. 957,064, to Charles R. Keeran, granted May 3, 1910, shows an overall closure of the "Mason jar" type, consisting of a piece of oil paper 9, which does not overlap the lip of a bottle, and is in contact with the contents of the bottle. It is adhered to a layer of blotting paper 8, by sealing wax, rubber or the like, and above but not adhered to it is a cushion disc 7, of soft pulp board.

Patent No. 408,177, to Daniel W. Johnson, granted July 30, 1889, shows a closure of the "Mason jar" type, with a "sealing gasket" of "parchment or parchmentized fiber," secured to a "felted body" by being cemented in any suitable manner. This is not a paper spot crown.

Center spot crowns were not new with Warth but were known to the art for years before any date of invention [fol. 2071] shown by Warth, as was also the use of composition cork discs. The use of paper for the center spot or a fusible binding medium were not new, as both had been disclosed by McManus in his patent No. 1,339,066.

From a consideration of the prior art, it seems to me that if there be invention in this patent, it must reside in the particular kind of facing material, and the particular kind of binder; but in view of the teaching of the prior art, especially of McManus No. 1,339,066, there was no invention over McManus No. 1,339,066 or the prior art in selecting a facing disc of hard high-gloss paper or gutta percha as the adhesive, but all that Warth accomplished by his patent in suit, No. 1,899,783, resulted from a mere substitution of material when the plaintiff desired to commercially produce the heat-fusible caps suggested by McManus.

Warth patent in suit No. 1,899,783 shows no novelty or invention and is invalid.

The fourth patent in suit is Reissue Patent No. 19,117 to Albin H. Warth, granted March 20, 1934, and discloses a Process of Producing Closures, of which claims 1 and 3, reading as follows, are in suit:

Claim 1:

"1. The improved method of manufacturing caps of the type having an interior disc of cushion material provided on its exposed face with a center spot, which comprises

providing spot material in strip form having one surface formed of an exposed continuous coating of water resistant [fol. 2072] adhesive which is normally hard at room temperature but becomes tacky upon the application of heat and having another surface to be exposed to the contents of a capped container, cutting from said strip a facing spot having one surface completely coated with said adhesive with a cap disposed beneath the portion of the strip from which the spot is cut, whereby the cutting operation positions the spot upon the cushion material with the coating between the spot and the cushion material, and upon assembly applying simultaneously to the spot pressure and sufficient heat to render the adhesive tacky, thereby causing the spot to adhere to the cushion material, and thereafter permitting the adhesive to cool and harden."

Claim 3:

"3. The improved method of manufacturing caps of the type having an interior disc of cushion material provided on its exposed face with a center spot, which comprises providing spot material in strip form having one surface formed of an exposed continuous coating of water resistant adhesive which is normally hard at room temperature but becomes tacky upon the application of heat and having another surface to be exposed to the contents of a capped container, cutting from said strip a facing spot having one surface completely coated with said adhesive with a cap disposed beneath the portion of the strip from which the spot is cut, whereby the cutting operation positions the spot [fol. 2073] upon the cushion material with the coating between the spot and the cushion material, and upon assembly applying simultaneously to the spot pressure and sufficient heat to render the adhesive tacky, thereby causing the spot to adhere to the cushion material and thereafter permitting the adhesive to cool and harden while subjecting the assembled unit to pressure."

This patent is for a method which is described as follows:

Warth supplies a strip of thermoplastically-coated facing material, such as metal foil or paper coated with gutta percha to a punch which cooperates with a die. A line of assembled crowns (that is, crowns having the metal shell and the cork disc therein) is fed step by step beneath this

die. With the assembled crowns at rest beneath the die, the plunger descends, cuts a center spot from the strip of facing material and presses it down against the cork with the adhesive in contact with the cork. In his illustrative drawings Warth has shown heat applied to the cutting plunger. This warmed plunger supplies sufficient heat to the center spot to make the thermoplastic tacky when it is pressed against the cork. Then the cutting plunger rises and the crown, with the center spot stuck on it, moved to the next position, where it is subjected again to pressure from a heated plunger. Then this plunger rises and the crown moves on to the fifth step, where a cold plunger under pressure is applied to the spot, the pressure being maintained for a considerable time while the adhesive is cooling. [fol. 2074] This method has great advantages over the plaintiff's first or slide machine, which operated about 50 or 60 strokes a minute, and has enabled plaintiff to design machines which successfully spot 500 per minute from each unit.

Although not satisfactory, plaintiff continued to use the slide machines for a period of about eight years, until a new machine, based on ideas furnished by Warth, working on a different method, was designed, built, and put in operation.

The defendant offered in evidence the following alleged prior art, which was not explained on the trial but has been discussed in the briefs on behalf of the respective parties:

Patent No. 1,339,066, to Charles E. McManus, one of the patents in suit, granted May 4, 1920, disclosed the fundamental idea of utilizing a thermoplastic for adhering the center spot to the crown, but did not show a machine or a method for applying the spots at any satisfactory commercial rate of speed.

Patent No. 1,213,926, to Charles E. McManus, granted January 30, 1917, shows merely a strip of facing material for making center spots. McManus proposed to provide his foil with a sheet of paper adhered to the foil by water glass, the other face of the paper being covered with a water soluble gum. The adhesive is not thermoplastic, and no method is shown by which the spots could be applied at a high rate of speed.

Patent No. 1,402,780, to Charles E. McManus, granted January 10, 1922, shows a bottle cap making machine. Such a machine was used to a very small extent in making spot crowns for nearly ten years. The strip material was coated

[fol. 2075] with a water-soluble adhesive, the cork disc was dampened by a moistening dauber, and then the disc cut out of the strip material was pressed down on this wetted surface, in an attempt to cause it to adhere. According to the testimony of McManus, he could never get any speed out of such a machine because of the tendency of the spot to float on top of the crown before it could be adhered to it.

Patent No. 1,199,026, to John Alberti, granted September 19, 1916, and Patent No. 1,401,300, to John Alberti, granted December 27, 1921, the second patent being referred to only as showing the state of the art. The first of these patents shows a metal foil spot held to the cork by a heat-set adhesive albumen, and the second, the machine for applying it.

Patent No. 993,288, to Leonard Bartlett, granted May 23, 1911, shows a machine devised to make the so-called American type of center spot crown, in which a rubber ring-shaped gasket 20 is held in place by a cupped piece of aluminum 21, the flanges of which extend over the ring-gasket, and the center of which is pasted by some adhesive material to the metal shell itself. Bartlett refers to the adhesive material as "paste or other adhesive material," which is to be deposited in the shell and then the cupped piece of metal pressed down upon it.

Patent No. 1,603,786, to Melchor Marsa, granted October 19, 1926, referred to only as showing the state of the art, shows a method for adhering cork discs in the shells. A sheet of sheet metal is spotted with a resinous cement in the center, the shells are cut out with the resinous cement in the center, the disc is inserted in the shell, the cork disc 16 [fol. 2076] placed on it, and then the resinous cement is melted by a gas flame and subjected to pressure to cause the cork disc to adhere to the shell. Does not relate to center spot crowns.

Patent No. 887,883, to William H. Wheeler, granted May 19, 1908, referred to only as showing the state of the art. It does not refer to the center spot crown, but shows a crown assembling machine in which the cork disc is adhered to the shell by means of collets of paraffin paper.

Patent No. 792,284, to William Painter, granted June 13, 1905, and Patent No. 887,838, to William Painter, granted May 19, 1908, both of which patents are referred to only as showing the state of the art, show respectively the original crown cap and machine for making it. The cork disc is

held in the shell by means of an adhesive placed on a paper collet placed between the cork and the shell, the adhesive being heated and then submitted to pressure to cause the disc to adhere to the shell. Neither patent relates to center spot crowns.

An examination of the prior art patents, it is true, shows some suggestions in one patent and some in another, of some of the elements of the Warth invention, such as the idea of coating a strip with an adhesive, but not one that was thermoplastic, the idea of cutting out a disc and applying it to a cork, but none of them disclosed the Warth method. To none, whatever was the teaching of the prior art, did it suggest the possibility of a method such as Warth's, which could be used to produce center spot crowns in such commercial quantities, at a very high speed, which is an impor- [fol. 2077] tant consideration in crown cap production. International v. New Process, 6 Fed. (2d) 420.

It is quite possible to carry out the Warth method by the use of a plunger, to which the heat is directly applied, although in that case there must be careful control of the heat in order to prevent the punch from becoming so hot as to cause a gumming of the punch itself from the tacky adhesive, or so cold as to supply insufficient heat to cause the spot to adhere.

Warth disclosed his method and it was unnecessary for him to show any apparatus for carrying it out. He was not limited to the particular form of apparatus illustrated as being useful for carrying out his method. It is sufficient that it has been shown that his illustrative apparatus is wholly operative, even if it was not the best which could be devised for commercial operation.

The Warth method has had large commercial success.

Men skilled in the art had long sought by various methods to accomplish what Warth teaches, and the fact that he succeeded where they failed is an evidence of invention, and the fact that parts of his method were old does not negative invention, as by the use of all the elements of his method he produces a new result in a different way.

Defendant in addition to the prior art patents relies upon the alleged prior use by the defendant and the alleged prior use by the plaintiff to limit or invalidate the patents.

Without going into any extended description of the method the defendant contends it used in making the center

spot caps for the Inecto Company, whatever it did was a [fol. 2078] temporary makeshift, which was abandoned as soon as it was able to perfect the making of the White Rock crown.

The only element of which it was able to present other than purely oral testimony, based solely on recollection, was that it obtained rolls of tinfoil and had surgical tissue combined with this foil. Defendant did not produce the machine nor any of the spot crowns which it claims that it used and made, and neither such machine nor spot crowns are in existence. No such machine was reproduced and proof offered that the operation which is described was possible. No drawings or other contemporaneous documentary proof was offered as to the method which was carried out by the machine, or as to the construction of the machine itself. The evidence offered as to the attachment made by Nagy for defendant, having a die for cutting center spots, is immaterial to the issue, as that attachment was made for the White Rock type of crown, and defendant's contention that it was changed by defendant itself, to adapt it to the making of the spot caps for the Inecto Company, is not supported by any documentary evidence. The testimony of Benno Cohn, Secretary of the defendant, and Charles H. Rasmussen, Superintendent of the defendant, given ten years after the alleged event, and based entirely on recollection is the proof on which defendant relies as to the alleged method.

The remaining officers and employees of defendant called, were Jay Bernard Eisen, who did not enter the defendant's employ until after the alleged making of the crowns in ques- [fol. 2079] tion, Jesse Gutmann, Vice President and Sales Manager, who knew nothing as to manufacture and production of the alleged Inecto crowns, but did negotiate the sale of the center spots to the Inecto Company, Ferdinand Gutmann, President of the defendant, who knew nothing of their production, and Samuel Cohn, Treasurer of the defendant, who knew that the Inecto crowns were made and approved of the expenditures involved, but did not testify as to method. None of the defendant's mechanics were called, although it is claimed the changes to its mechanism were made by its own mechanics, nor were such mechanics named or the failure to call them explained, although Superintendent Rasmussen was requested to look them up and said he would do so, and defendant had available its employees' time-book going back as far as 1921.

The fact that defendant has sufficiently proved the purchase of the tinfoil strips in 1925 does not prove the method, nor does the fact that they were used in some manner prove that the Warth method was used, as there were many different ways in which the adhesive strip could have been used other than in the way described by the witnesses.

Without questioning in any way the belief of Cohn and Rasmussen in the truth of their testimony, it is too uncertain, based only on recollection of what is alleged to have happened ten years before, to furnish proof beyond reasonable doubt, to anticipate the Warth method patents in issue. And in addition we must not forget that even the alleged prior use was abandoned and not resorted to when three years later defendant began making spot crowns.

[fol. 2080] The evidence of plaintiff's expert Weisenburg corroborated by Wilbur, as to the reproduction of the machine described by Cohn, and the results obtained in following the method described by Cohn, as shown by the crowns offered in evidence, is quite convincing that it was not possible, with such a machine, to produce commercial spot crowns, which leads to the belief that Cohn and Rasmussen must unconsciously have made some error in their recollection after the long period of years.

Of course, in the limited time at Weisenburg's disposal during the trial, the tests were necessarily ex parte, but plaintiff offered to repeat the tests inter partes, which offer defendant ignored.

The defendant's excuses for abandoning its alleged prior use, without going into details, are not convincing, and the actions of the defendant when it decided to make the spot crowns in 1928, clearly stamp whatever it did in 1925 as an abandoned experiment. Further, the proofs as to the paraffin coating of the Inecto spot crowns lead me to the belief that there is some error as to the method which Cohn and Rasmussen described as that used in 1925.

The alleged prior use of plaintiff asserted by the defendant is that of plaintiff's first or slide machine, in which a strip of tinfoil and a separate strip of gutta percha tissue were fed together beneath a cutting punch which punched out the two discs and deposited them in a cavity, in a movable slide. Then, the slide moved horizontally to carry out the cutout discs beneath an electrically heated suction plunger which picked up the two discs out of the cavity in

the slide. Then, the slide again moved from beneath the [fol. 2081] punch back to its original position, and the heated plunger with the discs sucked against its face was moved downward to deposit the discs on the cork of an assembled crown, to stick the spot to the cork disc, the suction pressure being released at the same time and changed to blowing, to help remove the spot from the end of the heated punch. The pressure of this heated punch caused the gutta percha to stick to the cork and also to the foil spot. The finished crown was then ejected from the machine. The combination of steps defined in the Warth methods of the patents in suit are not found in the plaintiff's first or slide machine, and it does not anticipate.

Defendant contends that it does not infringe because in its machine heat is not applied directly to the punch. This contention appears to me to overlook the requirements of the claims.

Claims 1 and 3 each provide, "and upon assembly applying simultaneously to the spot pressure and sufficient heat to render the adhesive tacky thereby causing the spot to adhere to the cushion material."

It is true that the defendant as does the plaintiff in commercial practice, instead of applying the heat directly to the punch as illustrated in the drawing of the Warth reissue patent No. 19,117 in suit preliminarily heats the cork disc.

Defendant's electrical preheating and post heating plungers are as close to the punch as is practicable and engage the cork disc at stations immediately preceding and following the punch station. The sole purpose of preheating the cork immediately in advance of the punch is to create heat, which will be available at the instant the spot [fol. 2082] is deposited, so that there will be provided the combined effect of heat and pressure. In the defendant's Johnson machines, the temperature of the punch, although heat is not directly applied, is as high as 140° (gutta percha becomes tacky at about 120°). While the heat in the punch is not sufficient alone to effect the desired stick it enables the operation to be conducted with less heat being applied to the cork, which tends to blacken and become scorched when too much heat is applied.

The claims in suit are not limited to the application of heat directly to the punch, and they are not so limited by the drawing offered by Warth in the prosecution of his

patent, simply for the purpose of illustrating a suitable means for effecting the simultaneous application of heat and pressure at the instant of depositing the spot.

The prior art did not, nor do I find anything in the records of the Patent Office actions which limit the claims in suit to producing in any particular way the heat which is utilized at the instant of assembly.

The defendant's contention that it was using a method involving the application of pressure to the caps in a cooling drum while the adhesive cools and hardens, at least as early as August 8, 1933, which was prior to the application for reissue, has no bearing on the validity of claim 1 which appeared in the original patent and was carried over into the reissue. It has no bearing on claim 3, which is like claim 1, except that it specifies the additional step of applying pressure while the adhesive is cooling and hardening. The application for reissue was filed as soon as it was dis- [fol. 2083] covered that the claims of the original patent did not specifically cover the "cooling under pressure" step, and even if defendant may have been using a process as defined in claim 3, including the cooling under pressure, prior to the date of application for reissue, such use does not anticipate claim 3.

Defendant infringed claim 1, carried over from the original patent, and since the reissue was filed to obtain more limited claims acquired no intervening rights. Abercrombie & Fitch Co., et al. v. Baldwin, et al., 245 U. S. 198; Babcock & Wilcox Co. v. Springfield Boiler Co., et al., 16 Fed. (2d) 964; Ball and Roller Bearing Co. v. F. C. Sanford Mfg. Co., 297 Fed. 163; Maitland v. Goetz Mfg. Co., 86 Fed. 124; Vortex Mfg. Co., et al. v. F. N. Burt Co., Limited, 297 Fed. 513; Hawie Mfg. Co. v. Hatheway Mfg. Co., et al., 27 Fed. (2d) 937; Steiner & Voegtly Hardware Co. v. Tabor Sash Co., 178 Fed. 831.

There was no laches in the application for the reissue which voided the claim. Motion Picture Patents Co. v. Laemmle, 214 Fed. 787.

The question of the speed of the defendant's machines does not seem to me to be in any sense controlling. The defendant's Cohn and Johnson machines are different from plaintiff's, but that machinery operates in accordance with the Warth method, and that defendant has not been able to equal plaintiff's high rate of production is no defense.

Elyria Iron & Steel Co. v. Mohegan Tube Co., 7 Fed. (2d) 830, 831; Waxham v. Smith and The Buckeye Incubator Company, 55 Sup. Ct., 277.

Defendant also denies infringement because of the difference in amount of pressure which it uses on its post-heat- [fol. 2084] ing plunger, or on its cutting punch, as compared with the pressure under which the spot is held while the adhesive is cooling. Defendant also attempts to distinguish from the Warth method when operating under the Cohn patent, in that it says, the cork disc has not been firmly adhered to the metal shell when the center spot is applied to the cork disc.

Neither the disclosure nor the claims of Warth limit the use of pressure solely at the cutting punch. Defendant applies heat and pressure to cause "the spot to adhere to the cushion material" or to "effect adhesion" to the cork before the plungers of the cooling drum are reached, and that constitutes infringement. The adhesion having been caused before the plungers of the cooling drum are reached, the pressure applied by the plungers is immaterial.

The Warth reissue patent, No. 19,117, as to the claims in suit is valid and infringed.

The fifth patent in suit is the Warth patent No. 1,956,-481, of which claims 6 and 16, reading as follows, are in issue:

Claim 6:

"6. In a cap which includes a metal shell, a cushion liner of cork, a center facing of metal foil of less diameter than the cushion liner positioned on the latter, and a stratum of heat-fusible adhesive interposed between the facing and liner and uniting the two, said stratum comprising a cellulose derivative adhesive and a modifying agent enhancing the adhesive characteristics of said derivative."

[fol. 2085] Claim 16:

"16. In a cap which includes a metal shell, a cushion liner of cork, a center facing of metal foil, and a stratum of heat-fusible adhesive interposed between the facing and cork cushion and uniting the two, said stratum comprising a nitro-cellulose adhesive and resin."

The patent is for a spot crown and liner material therefor, and the specification describes a center spot crown,

in which the center spot is adhered to the cork disc by a suitable cellulose derivative, such as nitrocellulose, to which a modifying agent to enhance the adhesive characteristics of the cellulose derivative has been added, such modifying agent being a resin and preferably a synthetic resin.

The defendant offered in evidence the following alleged prior art patents, but did not explain them on the trial. They are discussed in the briefs of the respective parties.

Patent No. 1,199,026, to John Alberti, granted September 19, 1916, shows a closure with heat coagulated albumen adhesive.

Patent No. 1,339,066, to Charles E. McManus, granted May 4, 1920, shows Bottle-Closure with resin-thermoplastic adhesive.

Patent No. 1,710,453, to Maurice Valentine Hitt, granted April 23, 1929, shows a nitrocellulose coating composition and film made therefrom, which in addition to the nitrocellulose contains many solvents and plasticizers, and in some cases resins are added. The composition is not thermoplastic. The fact that the Hitt patent number may be [fol. 2086] found on the cans in which 4620 is contained, does not prove that the Hitt material is the same as 4620. While it may well be that 4620 may employ the invention of Hitt, it may, because of different proportions of the materials, or because different materials are used, be wholly unlike the composition of the Hitt patent for some purposes. This is the fact in so far as this case is concerned, as 4620 is a thermoplastic, and the material of the Hitt patent is not.

The Article in the June or July, 1932, number of the duPont Magazine, extolling the virtues of 4620.

Patent No. 1,325,075, to Joseph J. Byers, granted December 16, 1919, shows a composite sheet stuck together with some cellulose derivative mixed with a non-drying vegetable oil, such as caster oil. The use of nitrocellulose alone as an adhesive was known, and nitrocellulose as an adhesive was old, but it is not thermoplastic. The patentee on page 1, beginning at line 72, states that a cement may be prepared by dissolving some cellulose derivative in any suitable solvent, such as acetone and alcohol, and on page 3, lines 40 to 44, he also states that heat applied in conjunction with pressure will cause the substance to act as a permanent cement.

Patent No. 1,389,084, to Lawson B. Wilson, granted August 30, 1921, shows a plastic cement for repair or mending, comprising celluloid, acetone and a phenol, to which Wilson suggests may be added certain softening agents, fillers and pigments. Among the fillers suggested are shellac, gums and resins of various kinds. It is true that if phenol were omitted, and if the proper kind of resin, and [fol. 2087] in the correct proportions to the nitrocellulose were used, Wilson would have a thermoplastic cement, but Wilson makes no suggestion of the thermoplasticity, and no suggestion of omitting phenol.

Reissue patent No. 16,803, to Edmund M. Flaherty, granted November 29, 1927, shows a low viscosity lacquer and film produced therefrom. This lacquer is not thermoplastic, and I do not see the relevancy of that patent.

Patent No. 1,554,033, to Ebenezer Emmet Reid, granted September 15, 1925, shows a cellulose composition, which is a combination of a cellulose derivative with a butyl phthalate. No proof was offered to show whether butyl phthalate is or is not a resin, but as Reid says one of the uses to which his material may be put is for varnishes, it can not be a thermoplastic. A varnish which would become tacky at a low heat would be unusable.

Patent No. 983,319, to Eugene C. Smith and Victor E. Smith, granted February 7, 1911, shows an overall covering for a cork crown, the adhesive to be used being a water-soluble adhesive and not a thermoplastic, and consisting of glue, glycerine and sugar or molasses.

The following patents to Albin H. Warth, all of which are referred to as showing the state of the art.

Patent No. 1,867,637, granted July 19, 1932, shows a closure and interior facing therefor, using a gutta percha or gum adhesive.

Patent No. 1,908,498, granted May 9, 1933, shows method of manufacturing liner material for container closures, with a gutta percha adhesive.

[fol. 2088] Patent No. 1,788,260, granted January 6, 1931. This is the original reissue No. 19,117, and shows process of producing closures using gum adhesive mixed with vegetable oil.

The ordinary center spot cap disclosed in the patent in suit differs only from the old and well known type of center spot cap, in that instead of being secured by dammar

BLANK

PAGE

BLANK

PAGE

gum, gutta percha, albumen, or any desired adhesive specified in the prior art, it is secured by means of a cellulose derivative adhesive, or specifically, a cellulose derivative and a resin.

It seems to me that the nitrocellulose adhesive called for by claims 6 and 16 is disclosed in the prior art, particularly in Byers patent No. 1,325,075.

In any event, the adhesive disclosed is a thermoplastic heat-fusible material, and its use represents only a substitution of material over the prior art, and no invention.

The contention of the plaintiff that Warth conceived the invention and reduced it to practice in the Fall of 1926 is erroneous. Whatever those experiments were, they seem to have been abandoned, because on receipt of the first sample of duPont Company 4620, January, 1932, Warth began to experiment with it the same as did the defendant, with the result that defendant made commercial shipments in June and July, 1933, whereas plaintiff did not use 4620 commercially until June, 1934.

If Warth had invented and reduced to practice the nitrocellulose resin adhesive in 1926, it is difficult to believe that he would have, about three years thereafter, made the affidavit filed May 5, 1929, in the prosecution of Serial No. [fol. 2089] 360,895, in which he claimed to have discovered the desirable properties of gutta percha as an adhesive for center spot caps, or made a duplicate of that affidavit on December 22, 1932, in Serial No. 492,546, filed October 31, 1930. This last mentioned affidavit was not shown to Dr. Warth but it appears in the certified copy of the file of No. 492,546, Exhibit A.

As 4620 is superior to gutta percha, and both of these affidavits were made after January, 1932, when Dr. Warth said they first received 4620, it seems quite clear to me that Dr. Warth had not invented and reduced to practice a cellulose derivative adhesive in the Fall of 1926 nor had he progressed very far with his experiments with 4620.

The testimony of Mr. McManus, President of the plaintiff, Mr. Weisenburg, plaintiff's engineer, and Mr. Wilbur, a chemist for plaintiff, is quite convincing, that Dr. Warth had not succeeded in 1930, and that Mr. Weisenburg and Mr. Wilbur were still working on nitrocellulose and resins in 1931. This is inconsistent with the plaintiff's claim of

invention and reduction to practice by Warth in the Fall of 1926.

Dr. Warth had been trying to obtain a suitable nitrocellulose adhesive from the duPont Company and had obtained several kinds of nitrocellulose adhesives from them.

Finally Mr. Foley, of the duPont Company, told Dr. Warth that the company had put out an adhesive, No. 4620, which he (Mr. Foley) thought would be suitable for Dr. Warth's purpose. Mr. Foley knew that Dr. Warth wanted such an adhesive for applying center spots to caps.

Both plaintiff and defendant are using the patented prod-
[fol. 2090] uct of the duPont Company, and I am unable to find invention in the Warth patent in suit, No. 1,956,481.

The Warth patent No. 1,956,481, claims 6 and 16 in suit, is invalid for lack of invention.

The sixth patent in suit is the Warth patent No. 1,967,-195, of which claims 1, 2 and 3, reading as follows, are in suit:

Claim 1:

"1. The method of assembling linings for sealing pads in receptacle closure caps, consisting in providing caps with sealing pads therein and a web of lining material arranged with an adhesive surface non-viscous at normal temperature, heating the pads in the caps, and severing linings from the web of lining material and assembling the linings as they are severed from the web in the caps with the adhesive surface in contact with the heated pads to render the adhesive viscous and effect adhesion of the linings to the pads."

Claim 2:

"2. The method of assembling linings for sealing pads in receptacle closure caps, consisting in providing caps with sealing pads therein and a web of lining material arranged with an adhesive surface non-viscous at normal temperature, heating the pads in the caps, severing linings from the web of lining material and assembling the linings as they are severed from the web in the caps with the adhesive
[fol. 2091] surface in contact with the heated pads to render the adhesive viscous and effect adhesion of the linings to the pads, and then placing the linings in the caps under heat and pressure to effect an intimate adhesion between the linings and pads."

Claim 3:

"3. The method of assembling linings for sealing pads in receptacle closure caps, consisting in providing caps with sealing pads therein and a web of lining material arranged with an adhesive surface non-viscous at normal temperature, heating the pads in the caps, severing the linings from the web of lining material and assembling the linings as they are severed from the web in the caps with the adhesive surface in contact with the heated pads to render the adhesive viscous and effect adhesion of the linings to the pads, then placing the linings in the caps under heat and pressure to effect an intimate adhesion between the linings and pads, and then placing the linings assembled in the caps under pressure during the cooling thereof."

This patent discloses a method of manufacturing bottle caps.

The method claimed comprises punching the center spot from a strip of thermoplastically-coated material, applying such spot to the cork disc with heat, obtained by preheating the cork disc, and pressure, and then allowing the adhesive to cool with pressure applied to the spot.

[fol. 2092] This is the same method as that described and claimed in Warth Reissue Patent No. 19,117, which was a generic method patent, except that in the method of Reissue Patent No. 19,117, he left it to choice as to how the heat for the adhesive was to be obtained, whereas in Patent No. 1,967,195 in suit, the specific patent, he included the additional limitation that the heat for the adhesive was to be obtained by preheating the cork disc.

The defendant offered in evidence the following alleged prior art patents, which were not explained on the trial, but were discussed in the briefs of the respective parties.

Patent No. 1,199,026, to John Alberti, granted September 19, 1916, shows a metal foil spot held to the cork by a heat-set adhesive albumen.

Patent No. 1,339,066, to Charles E. McManus, granted May 4, 1920, discloses the fundamental idea of utilizing a thermoplastic for adhering the center spot to the crown, but did not show a machine or a method for applying the spots at any satisfactory commercial rate of speed.

Patent No. 1,213,926, to Charles E. McManus, granted January 30, 1917, shows merely a strip of facing material

for making center spots. McManus proposed to provide his foil with a sheet of paper adhered to the foil by water-glass, the other face of the paper being covered with a water-soluble gum. The adhesive is not thermoplastic, and no method is shown by which the spots could be applied at a high rate of speed.

Patent No. 1,402,780, to Charles E. McManus, granted January 10, 1922, shows a bottle cap making machine. Such a machine was used to a very small extent in making spot [fol. 2093] crowns, for nearly ten years. The strip material was coated with a water-soluble adhesive, the cork disc was dampened by a moistening dauber, and then the disc cut out of the strip material was pressed down on this wetted surface, in an attempt to cause it to adhere. According to the testimony of McManus, he could never get any speed out of such a machine, because of the tendency of the spot to float on top of the crown before it could be adhered to it.

Patent No. 993,288, to Leonard Bartlett, granted May 23, 1911, shows a machine devised to make the so-called American type of center spot crown, in which a rubber ring-shaped gasket 20 is held in place by a cupped piece of aluminum 21, the flanges of which extend over the ring-gasket, and the center of which is pasted by some adhesive material to the metal shell itself. Bartlett refers to the adhesive material as "paste or other adhesive material," which is deposited in the shell, and then the cupped piece of metal pressed down upon it.

Patent No. 1,852,578, to John A. Johnson, granted April 5, 1932, shows a method and apparatus for assembling linings in receptacle closure caps. The method claims of that patent, 28, 29 and 30, were copied into the second divisional application, serial number 664,410, and the Warth-Johnson interference 66,201 was declared, which resulted in an award of priority to Warth. This interference will be more fully discussed later.

Patents to Alexander Bogdanffy, No. 1,169,608, granted January 25, 1916; No. 1,053,565, granted February 18, 1913; and No. 1,053,898, granted February 18, 1913. Each shows [fol. 2094] a machine for making the standard non-spotted crown cap, the cork disc being adhered to the metal shell by a heat-fusible (usually resinous) adhesive. None of them called for the heating of the cork disc before the spot is applied thereto.

Patents to William Painter, No. 468,226, granted February 2, 1892, No. 792,284, granted June 13, 1905, and No. 887,838, granted May 10, 1908; the last two referred to only as showing the state of the art. The first is for the original bottle-sealing device of Painter, and the two latter are for the original crown cork patents in which a heat-fusible adhesive was used to hold the cork disc to the shell.

Patent No. 1,401,300, to Emilio Alberti and John Alberti, granted December 27, 1921, referred to only as showing the state of the art, shows a machine for manufacturing closures for bottles and other receptacles. It does not teach the use of a thermoplastic adhesive, and did not suggest the application of heat to the cork before the spot is applied.

Patent No. 1,134,031, to Robert G. Clark, granted March 30, 1915, referred to only as showing the state of the art, shows bottle cap assembling machine, and has no bearing on any method of applying crown caps to corks.

Patent No. 887,883, to William H. Wheeler, granted May 19, 1908, referred to only as showing the state of the art, shows an assembling machine which has no relation to center spots.

As I have said when considering the prior art as to Warth Reissue Patent No. 19,117, and for the same reasons, the prior art does not suggest the possibility of a method such as Warth's, which could be used to produce center spot [fol. 2095] crowns in such commercial quantities, at very high speed.

It is unnecessary to repeat what I said with reference to the alleged prior uses by defendant and plaintiff, in my discussion of Warth Reissue Patent No. 19,117, or any other defenses, because whatever I then said, so far as it is applicable here, I reassert as though repeated here.

The parent Warth application resulting in his patent No. 1,788,260, and which later became Reissue No. 19,117, was filed on January 7, 1927, Serial No. 159,743. It contained in addition to the broad idea of using heat and pressure simultaneously with the deposit of the spot, the specific disclosure, as suitable procedure, the preheating step. It is true as contended by the defendant, the description of preheating which was originally contained in this application was cancelled by amendment, on December 3, 1930, but it is also true that at the time this description of the "preheating" procedure was cancelled, Warth had on file a divisional application, Serial No. 494,201, which had been

filed on November 7, 1930, prior to the date of cancellation of the descriptive matter from the parent case. From this divisional application, a second division, Serial No. 664,410, was filed on April 4, 1933, containing precisely the three claims in suit and the patent issued, after an interference on this application. Therefore, Warth had in the Patent Office a complete disclosure of this preheating, from January 7, 1927, when the parent application was filed, until April 4, 1933, when the application resulting in Warth Patent No. 1,967,195 in suit was filed. The subject matter was not [fol. 2096] abandoned, as suggested by defendant, but was specifically reserved by continuous inclusion in the divisional application, and later in the second division. This has been approved and is the usual practice. Writer v. Kiwad, 63 Fed. (2d) 259.

Defendant urges as a defense that it purchased certain machines from Johnson in 1928, and that having used the machines, it is entitled to continue to do so, as well as to use additional machines which it purchased in 1933.

This brings us to a consideration of the Warth-Johnson Interference, No. 66,201.

There was no delay in provoking the interference with Johnson.

Plaintiff discovered early in 1933, the Johnson patent No. 1,852,578, dated April 5, 1932, on an application filed November 26, 1929, and immediately provoked the interference by copying the claims of the patent.

Warth did not copy the claims in the first division, Serial No. 494,201, filed November 7, 1930, but carved out of the same the second division for the interference.

There was no delay on the part of Warth after receiving notice of the Johnson patent.

After a preliminary motion, Warth's attorneys proceeded to take testimony and subpoenaed Johnson as their first witness, and Johnson offered to settle.

A settlement was finally arrived at whereby Johnson assigned his patent No. 1,852,578 to plaintiff, and was given a license under his patent, and also under plaintiff's patent No. 1,788,260, to continue the manufacture of the machines for plaintiff's licensees.

[fol. 2097] Counsel for Johnson and Warth did not care to take the responsibility of deciding the question of priority between Warth and Johnson, therefore those instruments

were placed in escrow pending final determination of the interference by the Patent Office, and the assignment remained in escrow until the Patent Office decided the question at final hearing.

The decision of the Examiner of Interferences was in favor of Warth.

Defendant contends that plaintiff should have made an election as between the Johnson patent and Warth application, after the license and assignment were executed, rather than permit the Patent Office to settle the question, and in support of that contention refers to Rule 94 of the Patent Office Rules of Practice.

This contention was not sustained.

Plaintiff did not have the legal title entitling it to make such an election until the interference was decided by the Patent Office as the assignment was in escrow.

Notwithstanding that plaintiff was convinced that the claims properly belonged in the Warth application, it was not possible to make the election in favor of the Warth application, and plaintiff could pursue no other course.

The Patent Office was fully informed as to the situation.

Rule 94 did not apply as it required an election when two applications of common ownership are involved in an interference, but did not permit an election in favor of an application when it is involved in interference with a patent. Even if plaintiff had held the assignment which it did not, [fol. 2098] it could not have made the election in favor of the application. Chillas v. Weisberg, 1928 Commissioner's Decisions, p. 24.

Defendant cites United Chromium v. General Motors Corp., 11 Fed. Supp. 694, but that case seems to me to be distinguishable, as in that case election was made in favor of the patentee by the applicant filing a concession of priority.

The decision of the Patent Office in an interference proceeding does not bind the Court, but the question of priority of invention, when properly raised, may be litigated in an action, and assuming that plaintiff on the evidence was convinced that Warth was the first inventor, it could not properly concede priority to Johnson, and with the assignment in escrow, it did not then have legal title to the Johnson patent.

Johnson's claims were limited to the step of preheating the cork, and as late as October, 1928, Johnson had not

manufactured a machine for practicing such a method. The earlier 1928 machines, sold to the Cuban concern in March, to Gutmann in July, and to Armstrong in May, had no preheater.

It appears to me that the only difference between these machines and the machine purchased by Gutmann in August, 1928, was the fact that a drum was applied to the latter machine, for permitting the crowns to cool under pressure.

Johnson did visit plaintiff's plant in the early part of 1928, and was taken by McManus into the spotting department, and during Johnson's visit there, McManus says there was some discussion of patents relating to the spotting machinery, and this is corroborated by Johnson's letter to the Armstrong Company, on April 24, 1928.

[fol. 2099] Although Johnson had been working since early in 1927, to perfect a machine, he had not discovered either the importance of cooling under pressure, or the advantage of preheating the cork immediately in advance of the cutting punch.

Warth's machines had been in use since 1926, drawings of the machines being in evidence. These drawings were for three machines to supplement the three identical Warth machines at that time in actual use, as shown by the January, 1927, appropriation for three additional machines.

The preheating was disclosed in the Warth application filed January 7, 1927.

The defendant's two machines, purchased in July and August, 1928, did not have a preheater, and did not embody the method of the Warth patent, No. 1,967,195, in suit.

The decision of the Patent Office in the interference was in entire accord with the facts.

The fact that Johnson, in 1929, built some machines for the plaintiff on special order for plaintiff's own use, does not affect the validity of the Warth patents, and does not anticipate a divisional application. American Chain Co. v. Franklin New York Co., 34 Fed. (2d) 551-555.

There was no anticipation by defendant's 1928 use, whatever method it used.

Defendant purchased two machines from Johnson, in July and August, 1928, and it is not proved that its 1928 machines had a preheater; on the contrary, Johnson admitted that prior to October, 1928, he did not have preheaters on any machines, and there is no uncertainty on

this point, as the letters (Exhibit 36) show that he was then [fol. 2100] "working on what we call preheaters of the cork."

Johnson it is true testified, on direct examination, that the 1928 machines were all "like" his patent No. 1,852,578, and repeated this testimony when he identified the list of a number of machines, but he evidently did not mean that they had a preheater, since on cross examination he modified his testimony, when confronted by plaintiff with an actual photograph of March 1, 1928, Cuban machine, which he admitted had neither a drum nor a preheater. This machine, which Johnson said was exactly like the unsatisfactory machine shipped to the Armstrong Company, merely used two heating punches. Cohn admitted that the machine purchased by defendant, on July 17, 1928, was like the one shown in the photograph. The machine purchased by the defendant in August, 1928, had a drum, but there is no evidence that it had a preheater, and Johnson admits that it did not.

There is no evidence to show that the Johnson machines sold to others than plaintiff and identified on the list had a preheater, or what was their construction, aside from Johnson's statement, which he changed under cross examination. There is no proof of the date of the Johnson Catalogue, and it is therefore without value. The machines purchased by defendant from Johnson, in 1928, had no preheater, and I am convinced that defendant made no further purchase from Johnson until 1933, therefore the defendant has not proved any use of the preheating method, to anticipate the filing date of the first divisional application, November 7, 1930, or the filing date of the second divisional application, April [fol. 2101] 4, 1933. Even if there was evidence of the use of the Johnson machines during these periods, such user would not anticipate. From 1927 to 1930, Warth was prosecuting his broad claims to the method. The claims were not directed during this period to the Warth specific preheating step. Such manner of proceeding has been approved. Hartford-Empire Co. v. Nivison Weiskopf, 58 Fed. (2d) 701.

As soon as it came to Warth's attention that any one else was claiming the invention he, being unaware of what methods others were using, and having no knowledge of defendant's using the preheating method, proceeded as the statutes permitted, and in accordance with the practice recognized by the Patent Office and the courts. Overland Co. v. Packard Co., 274 U. S. 417.

In making the claims to the preheating step Warth was covering what he had invented, without any intent to expand his disclosures to cover later methods which had come to his attention. This has been approved by the courts. Carson v. American Smelting and Refining Co., 4 Fed. (2d) 463, 470; Remington Cash Register Co. v. National Cash Register Co., 6 Fed. (2d) 614; Overland Co. v. Packard Co., supra.

The case at bar is clearly distinguished on the facts from Westinghouse Electric & Manufacturing Co. v. Jeffrey-De-Witt Insulator Co., supra, and Dwight & Lloyd Sintering Co. v. Greenawalt, supra. In the Westinghouse case, there was no proof of special circumstances, and in the parent application the patentee had not claimed the invention of his delayed divisional application, either generically or specifically. In the Dwight & Lloyd case, there had been [fol. 2102] open, notorious infringement for thirteen years, known to the plaintiff, who had been in interference proceedings with the defendant, and there were no special circumstances, as here, justifying the delay.

The contention of the defendant that if the Warth Reissue Patent No. 19,117 be interpreted to cover generically the step of preheating the pads, it anticipates the divisional Warth patent No. 1,967,195, is not sustained.

The claims in suit in the Reissue Patent No. 19,117 require "and upon assembly applying simultaneously to the spot pressure and sufficient heat to render the adhesive tacky."

The claims in suit in the divisional patent No. 1,967,195 require "heating the pads in the caps."

None of the claims of the divisional patent is readable upon the disclosure of the reissue, and therefore when the Reissue Patent expires, the public will be free to practice the method without infringing the divisional patent, that is, the public may employ any method of obtaining the heat at the instant of assembly except the specific "heating the pads in the caps" covered in the later patent.

The Reissue Patent is the generic and the divisional the specific patent, and therefore the reissue does not anticipate the divisional patent.

It does not seem to me that the result of the issuance of the divisional patent extends the monopoly of the Johnson patent. Johnson was not the first inventor of the method, and the patent could not afford a monopoly on the method.

There was no delay on the part of plaintiff when it first learned of the improper grant to Johnson, and to hold the patent invalid on that ground would be to penalize the [fol. 2103] plaintiff because of the inadvertent grant to another, who was not the original inventor.

In addition to what has been said with reference to Warth Reissue patent No. 19,117 as to infringement, which need not be repeated here, it is also true that the defendant does use the method of preheating as described in the claims in suit, of Warth patent No. 1,967,195.

The Warth patent No. 1,967,195 as to the claims in suit is valid and infringed.

This leaves for consideration only patent No. 1,921,808, issued to Benno Cohn, assignor to Ferdinand Gutmann & Co., granted August 8, 1933, pleaded by the defendant as a counterclaim. The defendant is the owner of this patent.

The patent is for a method. The empty shells are fed into the machine from a hopper, then heated, an adhesive placed in the metal shell, the cork disc inserted in the metal shell, and the caps are then carried to the spotting mechanism so that the cork (either natural or composition) liner is put in the shell and a center spot inserted, all in one machine.

There are three claims to the patent and all are in suit, but I need not quote them.

The reply pleaded a general denial, which raises only the issue of infringement.

The defendant's charge of infringement is predicated on the fact that the Crown Cap Manufacturing Company of Brooklyn sent a standard Johnson assembling machine to Nagy to have an attachment added, that would place center spots on the corks while the crown was being assembled, and that Nagy delivered such a machine to the Crown Cap Manufacturing Company early in 1933 or late in 1932.

In July, 1933, the Crown Cap Manufacturing Company [fol. 2104] sold its assets, including this machine, to plaintiff.

Defendant's witness Fries said that he could never get this machine to work so that it could produce commercially. Whether or not there was something wrong in the manner in which the Crown Cap Company attempted to operate this machine, as contended by defendant's counsel, Fries says that he never could fully determine what the difficulty was, otherwise he would have corrected it. It certainly was his intention to go on manufacturing in accordance with the

method of this combined machine. I therefore believe that the machine would not work to produce commercially.

Fries remained in charge for four months after July, 1933, when the plaintiff took over the assets of the Crown Cap Manufacturing Company. During those four months this machine was never operated by the Crown Cap Manufacturing Company, by him or by any one in that plant.

This machine was sent to the Baltimore plant of plaintiff, it is still on the skids, has never been used by plaintiff, and has never been set up for operation.

There is no proof of any use of this machine by the plaintiff, and if the testimony of Fries be accepted, and I see no reason why it should not be, the machine would not work to produce commercially, therefore there is no proof of infringement.

McManus says that such a machine was never considered by him as having any value, because it was slow, and that there was no advantage in having the spotting machine connected to the assembling machine.

[fol. 2105] Taking all that has been said into consideration with the fact that if properly workable, which it was not, this machine, which was experimental, would have had a rate of production of about 200 a minute, as against plaintiff's machine which produces 500 a minute, the mere possession of this machine raises no inference even of a threat of infringement.

More than an inference is necessary to prove infringement, particularly of a method patent.

The plaintiff does not and has not infringed.

The defendant's counterclaim as to patent No. 1,921,808 is dismissed, on the ground of non-infringement.

A decree may be entered in accordance with this opinion, in favor of the plaintiff against the defendant on McManus patent No. 1,339,066; Warth Reissue patent No. 19,117; and Warth patent No. 1,967,195; and dismissing the defendant's counterclaim on Cohn patent No. 1,921,808; with four-sevenths costs and disbursements; and in favor of the defendant against the plaintiff dismissing the bill of complaint on the merits as to Warth patent No. 1,899,782; Warth patent No. 1,899,783; and Warth patent No. 1,956,481; with three-sevenths costs and disbursements.

Settle decree on notice.

Submit proposed findings of fact and conclusions of law, in accordance with this opinion, for the assistance of the

Court, as provided by Rule 70-½ of the Equity Rules and Rule 11 of the Equity Rules of this Court.

[fol. 2106] In United States District Court

[Title omitted]

Stipulation as to Findings of Fact and Conclusions of Law

It is hereby stipulated by and between the solicitors for the respective parties that the opinion of the Court filed herein March 2, 1936, may be considered as the findings of fact and conclusions of law in this case, pursuant to Rule 70½ of the Equity Rules and Rule 11 of the Equity Rules of this Court, reserving to both parties any and all rights of appeal as to any and all errors of fact or law that may be embodied in such findings and conclusions.

Dated March 11, 1936.

Gifford, Scull & Burgess, Solicitors for Plaintiff.
Hauff & Warland, Solicitors for Defendant.

[fol. 2107] In United States District Court

Present: Hon. Marcus B. Campbell, U. S. District Judge.

In Equity. No. 7371

Crown Cork & Seal Company, Inc., Plaintiff,

vs.

Ferdinand Gutmann & Co., Defendant

Interlocutory Decree—March 23, 1936

This cause having come on to be heard upon the pleadings and proofs of the respective parties and having been submitted on briefs for the respective parties, the Court having considered the same, and the parties having stipulated that the opinion of the Court filed March 2, 1936, may be considered as the findings of fact and conclusions of law in this case, and as a compliance with Rule 70½ of

the Equity Rules and Rule 11 of the Equity Rules of this Court, it is

Ordered, Adjudged and Decreed

1. That Letters Patent of the United States No. 1,339,066 issued to Charles E. McManus for Bottle Closures, dated May 4, 1920, are good and valid in law as to claims 3 and 8.

[fol. 2108] 2. That Reissue Letters Patent of the United States No. 19,117 issued to Albin H. Warth, assignor by mesne assignments to Crown Cork & Seal Company, Inc., for Process of Producing Closures, dated March 20, 1934, are good and valid in law as to claims 1 and 3.

3. That Letters Patent of the United States No. 1,967,195 issued to Albin H. Warth, assignor to Crown Cork & Seal Company, Inc., for Method of Manufacturing Bottle Caps, dated July 17, 1934, are good and valid in law as to claims 1, 2 and 3.

4. That the title to said Letters Patent No. 1,339,066, Reissue No. 19,117 and No. 1,967,195 and the inventions described and claimed in each of them is vested in the plaintiff.

5. That the defendant, Ferdinand Gutmann & Co., has infringed upon claims 3 and 8 of said Letters Patent No. 1,339,066 and upon claims 1 and 3 of said Reissue Letters Patent No. 19,117 and upon claims 1, 2 and 3 of said Letters Patent No. 1,967,195, and each of them, and upon the exclusive rights of the plaintiff thereunder.

6. That plaintiff recover from the defendant the gains, profits and advantages which it has received or made or which have arisen or accrued to it by reason of its said infringements and also the damages which the plaintiff has sustained by reason of said infringements.

7. That the said cause be referred to —— ——, as master pro hac vice to ascertain, state and report to the Court [fol. 2109] separate accounts of the gains, profits and advantages which the defendant has received or which have arisen or accrued to it by reason of said infringements of claims 3 and 8 of said Letters Patent No. 1,339,066; claims 1 and 3 of said Reissue Letters Patent No. 19,117, and claims 1, 2 and 3 of said Letters Patent No. 1,967,195 and

also the damages plaintiff has sustained by reason of said infringements.

8. That the plaintiff on said accounting have the right to an examination of said defendant and its officers, agents, servants, attorneys and workmen ore tenus and otherwise and also the production of the books, vouchers and other documents of the defendant, and that the defendant and its officers, agents, servants, attorneys and workmen attend for such purpose before such master from time to time as said master shall direct, and that the master and each party may from time to time during such accounting apply to the Court at the foot of this decree for such further directions as may be necessary.

9. That the defendant and its officers, agents, employees, workmen and confederates be enjoined and restrained permanently by injunction, hereby authorized to be issued, from directly or indirectly practicing the processes of claims 1 and 3 of said Reissue Letters Patent No. 19,117 and claims 1, 2 and 3 of said Letters Patent No. 1,967,195, or making or causing to be made, using or causing to be used, selling or causing to be sold products embodying the inventions of claims 3 and 8 of said Letters Patent [fol. 2110] No. 1,339,066, and from infringing upon or violating the exclusive rights of the plaintiff thereunder in any way whatsoever.

10. That the bill of complaint be and it hereby is dismissed as to Letters Patent of the United States No. 1,899,782 dated February 28, 1933, No. 1,899,783 dated February 28, 1933, and No. 1,956,481 dated April 24, 1934.

11. That the counterclaim be and it hereby is dismissed.

12. That the plaintiff recover from the defendant four-sevenths and that the defendant recover from the plaintiff three-sevenths of the costs to be taxed herein.

Marcus B. Campbell, United States District Judge.

Approved as to form.

Gifford, Scull & Burgess, Solicitors for Plaintiff.
Hauff & Warland, Solicitors for Defendant.

[fol. 2111] IN UNITED STATES DISTRICT COURT

[Title omitted]

DEFENDANT'S PETITION FOR APPEAL

The defendant, Ferdinand Gutmann & Co., conceiving itself aggrieved by the Interlocutory Decree made and entered herein on the 23rd day of March, 1936, does hereby appeal to the United States Circuit Court of Appeals for the Second Circuit, from that part of said decree which

1. Holds the patent to McManus, #1,339,066, dated May 4th, 1920, good and valid in law as to claims 3 and 8 and that the defendant has infringed said claims.

2. From that part of said decree which holds that Reissue Letters Patent of the United States, #19,117 to Albin H. Warth, dated March 20th, 1934, are good and valid in law as to claims 1 and 3 and that the defendant has infringed said claims.

3. From that part of the decree which holds that Letters Patent of the United States, #1,967,195 to Albin H. Warth, [fol. 2112] dated July 17th, 1934, are good and valid in law as to claims 1, 2 and 3 and that the defendant has infringed said claims.

4. From that part of the decree which holds that the counterclaim of defendant be and is dismissed.

That the reasons for said appeal are specified in the Assignment of Errors which is filed herewith, and it prays that this appeal may be allowed and a citation granted directed to the above named Crown Cork & Seal Co., Inc., commanding it to appear before the United States Circuit Court of Appeals for the Second Circuit, to do and receive what may appertain to justice to be done in the premises, and that a transcript of the record, proceedings and papers upon which said decree was made, may be duly authenticated and sent to the United States Circuit Court of Appeals for the Second Circuit.

Hauff & Warland, Solicitors for Defendant.

Dated, New York, March 24th, 1936.

ORDER ALLOWING APPEAL

Ordered, that the foregoing appeal be, and the same hereby is allowed.

Marcus B. Campbell, United States District Judge.

Dated, Brooklyn, N. Y., March 26th, 1936.

[fol. 2113] IN UNITED STATES DISTRICT COURT

[Title omitted]

DEFENDANT'S ASSIGNMENT OF ERRORS

Now Comes the defendant, Ferdinand Gutmann & Co., and presents with its accompanying Petition for Appeal from the Interlocutory Decree entered herein, the following Assignment of Errors:

1. The Court erred in holding the McManus Patent No. 1,339,066 as to claims 3 and 8 thereof to be valid in law and infringed.

2. The Court erred in holding that claims 3 and 8 of the McManus Patent in issue are not anticipated by the prior art.

3. The Court erred in holding that neither gutta percha nor any thermoplastic or heat fusible adhesive was used by the plaintiff or anyone prior to 1917 in the manufacture of center spot caps. (W. E. W.)

4. The Court erred in not holding that the use of gutta percha as an adhesive for center spots was used prior to [fol. 2114] July 1, 1915, as appears from the plaintiff's own testimony and the Preliminary Statement made by plaintiff's assignor in Interference No. 60,878.

5. The Court erred in not holding that the use of gutta percha as an adhesive was used in the bottle cap art long prior to the date of the application for the McManus patent.

6. The Court erred in holding that there was no laches on the part of plaintiff and its predecessor in title, viz., McManus, in waiting fourteen years and four months before bringing suit on the McManus patent.

7. The Court erred in not holding that center spot crown caps made in accordance with the McManus patent were used by all the manufacturers of center spot crowns without molestation by the plaintiff or McManus, its predecessor in title, for seventeen years before the beginning of the present suit.

8. The Court erred in holding that the correspondence between plaintiff and defendant in 1930 did not constitute an estoppel by plaintiff.

9. The Court having found that center spot caps per se, secured by any adhesive, were old, erred in holding that the mere selection of a particular adhesive by McManus constituted invention.

10. The Court erred in holding that what McManus did was much greater than a mere change of the adhesive.

[fol. 2115] 11. The Court erred in holding that what McManus did was the solving of a real problem and the turning of failure to success by means not even suggested by the prior art.

12. The Court erred in holding that the McManus patent is not limited to paper or parchment.

13. The Court erred in holding there was no evidence that defendant was misled by the conduct of McManus and the plaintiff.

14. The court erred in holding that the Reissue Patent to Albin H. Warth No. 19,117 dated March 20th, 1934, was good and valid as to claims 1 and 3 thereof and infringed by the defendant.

15. The Court erred in holding that Warth was not limited to the particular form of apparatus illustrated.

16. The Court erred in holding that Warth in his Re-issue Patent No. 19,117, produced a new result in a different way.

17. The Court erred in broadly construing the Warth Reissue Patent No. 19,117.

18. The Court erred in holding that the method set forth in Warth Re-issue Patent No. 19,117 was not disclosed in the prior art.

19. The Court, after finding that the patents to Bogdanffy and Painter showed that a heat fusible adhesive was used to [fol. 2116] secure the cork disc to the shell by the application of heat and pressure, erred in finding that there was invention in securing the center spot to the cork disc by the same adhesive and by the same method of utilizing heat and pressure that had been used in the Bogdanffy and Wheeler patents for securing the cork lining to the metal shell.

20. The Court erred in holding that the evidence offered as to the attachment made by Nagy for defendant having a die for cutting center spots is immaterial to the issue.

21. The Court erred in holding that the 300,000 caps having center spots cut from metal foil coated with gutta percha made by defendant for the Inecto Company was not an anticipation.

22. The Court erred in holding that the 300,000 caps made and sold to the Inecto Company by the defendant in 1925 was an abandoned experiment.

23. The Court erred in holding that the defendant's excuses for abandoning its alleged prior use without going into details were not convincing.

24. The Court erred in not holding that the heat and pressure used by plaintiff in its slide machine in 1915 anticipated claims 1 and 3 of the Warth Re-issue Patent in suit.

25. The Court erred in holding that claims 1 and 3 of the Warth Re-issue Patent in suit are not limited to the application of heat directly to the punch.

[fol. 2117] 26. The Court erred in holding that neither the prior art nor anything in the records of the Patent Office limits the claims in suit to producing in any particular way the heat which is utilized at the instant of assembly.

27. The Court erred in holding that there was no laches in the application for the Re-issue.

28. The Court erred in holding that neither the disclosure nor the claims of Warth limits the use of pressure solely at the cutting punch.

29. The Court erred in holding that defendant applies heat and pressure to cause the "spot to adhere to the

cushion material'' or to ''effect adhesion'' to the cork before the plungers of the cooling drums are reached.

30. The Court erred in holding that the pressure applied by the plungers in the cooling drum in defendant's method is immaterial.

31. The Court erred in holding that the testimony of plaintiff's witnesses Weisenburger and Wilbur showed that with the method described by defendant's witness Cohn it was not possible to produce commercial spot crowns.

32. The Court erred in holding that claims 1, 2 and 3 of the patent to Warth 1,967,195 are valid in law and infringed by defendant.

33. The Court erred in holding that what it had previously said in its Opinion about the prior uses by plaintiff and defendant in connection with the Re-issue Patent 19,117 to Warth applied to Patent No. 1,967,195.

34. The Court erred in holding that Patent No. 1,967,195 to Warth, the application for which was filed on April 4th, [fol. 2118] 1933, was a proper division of Patent No. 1,788,260 issued on January 6th, 1931.

35. The Court erred in holding that Warth's application No. 494,201, filed November 7th, 1930, showed the subject matter of Patent No. 1,967,195.

36. The Court erred in holding that the preheating of the cork was disclosed in the Warth application filed January 7th, 1927.

37. The Court erred in holding that the two machines purchased by Johnson from defendant in July and August, 1928, did not have a pre-heater and did not embody the method of Warth Patent No. 1,967,195.

38. The Court erred in holding that there was no anticipation by defendant's 1928 use, whatever method it used.

39. The Court erred in holding that the machines purchased by defendant from Johnson in 1928 had no preheater and that defendant made no further purchase from Johnson until 1933.

40. The Court erred in overruling defendant's contention to the effect that if Re-issue Patent No. 19,117 be interpreted

to cover generically the step of pre-heating the pads, it anticipates the divisional Warth Patent No. 1,967,195.

41. The Court erred in holding that the issue of the divisional patent did not extend the monopoly of the Johnson patent.

[fol. 2119] 42. The Court erred in holding that Warth and not Johnson was the first inventor of the method set forth in Patent No. 1,967,195.

43. The Court erred in not holding that defendant was licensed to use the method shown in the Johnson patent in view of the fact that it had bought in good faith such patented machines from Johnson more than two years before the divisional application for Patent No. 1,967,195 in suit was filed.

44. The Court erred in not finding that the plaintiff had purchased four machines from Johnson like those shown in his Patent No. 1,852,578 in 1929 and that Warth was guilty of laches in not applying for Patent No. 1,967,195 until April 4th, 1933, more than four years after defendant bought machines from Johnson.

45. The Court erred in dismissing defendant's counterclaim on the Benno Cohn Patent No. 1,921,808 and refusing an injunction after finding that the plaintiff had purchased such a machine in 1933 and now has such machines in its plant.

Wherefore, the defendant prays that the Decree entered herein on the 23rd day of March, 1936, be reversed and that a Decree be entered dismissing the Bill of Complaint and granting an injunction against the plaintiff to defendant on its counterclaim for infringement of the Benno Cohn Patent No. 1,921,808.

Dated, New York, N. Y., March 24th, 1936.

Hauff & Warland, Solicitors for Defendant.

[Title omitted]

PLAINTIFF'S PETITION FOR APPEAL

The plaintiff, Crown Cork & Seal Company, Inc., conceiving itself aggrieved by the decree made and entered herein on the 23rd day of March, 1936, does hereby appeal from the said decree to the United States Circuit Court of Appeals for the Second Circuit for the reasons specified in the assignment of errors which is filed herewith; and it prays that this appeal may be allowed and a citation issued directed to the above named defendant, Ferdinand Gutmann & Company, commanding it to appear before the United States Circuit Court of Appeals for the Second Circuit, to do and receive what may appertain to justice to be done in the premises, and that a transcript of the record, proceedings and papers upon which said decree was made may be duly authenticated and sent to the United States Circuit Court of Appeals for the Second Circuit.

Gifford, Scull & Burgess, Solicitors for Plaintiff.

Dated, New York, N. Y., March 31st, 1936.

[fol. 2122] ORDER ALLOWING APPEAL

The parties having entered into a stipulation dispensing with the filing of appeal bonds and said stipulation having been approved by the Court, it is hereby

Ordered, that the foregoing petition for appeal be, and the same hereby is, allowed.

Dated April 1, 1936.

Marcus B. Campbell, United States District Judge.

IN UNITED STATES DISTRICT COURT

[Title omitted]

PLAINTIFF'S ASSIGNMENT OF ERRORS

Now, comes the plaintiff, Crown Cork & Seal Company, Inc., and presents with its accompanying petition for ap-

peal from the decree entered herein, the following assignment of errors:

1. The Court erred in dismissing the bill of complaint as to Letters Patent to Warth No. 1,899,783 and No. 1,956,481.

[fol. 2123] 2. The Court erred in failing to grant the relief prayed for in the bill of complaint as to Letters Patent to Warth No. 1,899,783 and No. 1,956,481.

3. The Court erred in that it did not enter a decree finding that Letters Patent No. 1,899,783 to Warth is valid as to claim 4 thereof and has been infringed by the defendant.

4. The Court erred in that it did not enter a decree finding that Letters Patent No. 1,956,481 to Warth is valid as to claims 6 and 16 thereof and has been infringed by the defendant.

5. The Court erred in that it did not enter a decree for an injunction restraining the defendant from infringement of Letters Patent No. 1,899,783 and No. 1,956,481.

6. The Court erred in that it did not enter a decree awarding plaintiff an accounting for profits and damages by reason of the infringement by the defendant of Letters Patent No. 1,899,783 and No. 1,956,481.

Wherefore, the plaintiff prays that the decree entered herein on the 23rd day of March, 1936, insofar as it relates to Letters Patent No. 1,899,783 and No. 1,956,481, and each of them, be reversed, and that a decree be entered in accordance with the prayers of the bill of complaint herein with regard to said Letters Patents, and each of them, with costs to the plaintiff.

Gifford, Scull & Burgess, Solicitors for Plaintiff.

Dated, New York, N. Y., March 31st, 1936.

[fol. 2124] Citation, in usual form, showing service on Hauff & Warland, omitted in printing.

[Title omitted]

STIPULATION AND ORDER WAIVING EQUITY RULE 75

It is Hereby Stipulated and Agreed by and between the solicitors for the respective parties hereto, subject to the [fol. 2126] approval of the Court, that the transcript of record on the appeals taken by both parties and involving six patents shall include all of the evidence adduced at the trial in the form of question and answer, in lieu of the condensed statement thereof under Equity Rule 75.

Dated April 2nd, 1936.

Gifford, Scull & Burgess, Solicitors for Plaintiff-Appellant and Cross-Appellee. Hauff & Warland, Solicitors for Defendant-Appellee and Cross-Appellant.

So Ordered. Manton, United States Circuit Judge.

April 3, 1936.

[fol. 2127] IN UNITED STATES DISTRICT COURT

[Title omitted]

STIPULATION AND ORDER WAIVING BONDS

An Interlocutory Decree having been entered in the above entitled cause on the 23rd day of March, 1936, holding three of the patents in suit valid and infringed as to certain claims thereof and dismissing the defendant's counterclaim and also holding that three of the patents in suit are invalid, and both parties being about to appeal from said Decree, it is hereby stipulated that the furnishing of a bond to secure the cost of the appeal by both sides, be dispensed with.

Dated, New York, March 25th, 1936.

Hauff & Warland, Solicitors for Defendant. Gifford, Scull & Burgess, Solicitors for Plaintiff.

It is Ordered, that the above stipulation be approved.

Dated, Brooklyn, March 26th, 1936.

Marcus B. Campbell, U. S. District Judge.

[fol. 2128] IN UNITED STATES DISTRICT COURT

[Title omitted]

STIPULATION AS TO RECORD

Plaintiff and defendant having appealed in the above entitled cause and said appeals having been allowed, it is hereby stipulated and agreed by and between the solicitors for the respective parties that the following enumerated items shall constitute the transcript of record to be transmitted to the United States Circuit Court of Appeals for the Second Circuit:

1. Bill of Complaint.
2. Answer and counterclaim.
3. Reply to counterclaim.
4. Plaintiff's bill of particulars re claims, December 28, 1934.
5. Defendant's bill of particulars re anticipations, December 31, 1934.
6. Order, January 11, 1935, directing defendant to file bill of particulars.
7. Defendant's bill of particulars, January 18, 1935.
8. Plaintiff's bill of particulars re conception, etc., January 21, 1935.

[fol. 2129] 9. Plaintiff's motion for further particulars, January 26, 1935.

10. Defendant's bill of particulars, February 6, 1935.
11. Notice, May 7, 1935, re state of art references.
12. Stipulation, December 9, 1935.
13. Minutes of trial in question and answer form.
14. Plaintiff's Exhibits to be reproduced:

1. McManus Patent No. 1,339,066. Warth Patent No. 1,899,782. Warth Patent No. 1,899,783. Warth Reissue Patent No. 19,117. Warth Patent No. 1,967,195. Warth Patent No. 1,956,481.

2. Letters dated April 2, April 26 and July 18, 1934, to Ferdinand Gutmann & Co.

3. Stipulation, April 30, 1935, and translations of French patents No. 463,971 and No. 415,794.

13. Some interrogatories directed to defendant and answers thereto.

14. Johnson Patent No. 1,852,578.

15. Cohn Patent No. 1,921,808.

16. Chart of typical machine and procedure for making ordinary crowns.

17. Chart showing how center spot crowns are applied.

21. Chart illustrating Warth method in reissue patent in suit.

22. Another chart showing Warth method.

23. Chart showing method in Johnson and Cohn patents according to stipulation.

[fol. 2130] 29. List showing production by plaintiff of paper center spot crowns from 1928 to 1934.

30. List showing action of one or more typical purchasers from plaintiff from 1925 on.

31. List showing production by plaintiff of natural cork crowns from 1923 on.

32. List showing production by plaintiff of natural cork crowns from 1917 to date.

33. List showing manufacture by plaintiff of all types of spot crowns, metal foil and paper spot.

34. Record of typical users of metal foil spot crowns.

35. Photograph showing Cuban machine of March 1, 1928.

36. Letter dated October 5, 1928, from Johnson to Armstrong Cork Co.

37. Letters dated April 20 and April 24, 1928, between Johnson and Armstrong Cork Co.

38. Sketch by witness Cohn of machine used for producing Inecto caps.

39. Bill by Gutmann to Inecto, dated May 13, 1925.

40. Memorandum accompanying Plaintiff's Exhibit 39.

41. Photograph of machines shown by McManus to Johnson.

42. Photograph of machines shown by McManus to Johnson.

43. Chart made by witness Goebel showing sequence of steps in operation of machine developed under Goebel's supervision.

[fol. 2131] 44. Memorandum signed by W. F. Walker produced by witness Goebel.

45. Photographs accompanying Exhibit 44.

50. Appropriation No. 91,036 to cover money available for three aluminum spots to be applied to crown assembling machines, as per blue prints.

51. Paper dated April 15, 1925, referring to scrapping of three slide machines.

52. Photograph produced by witness Goebel showing machine used for combining two strips in one roll.

53. Appropriation No. 91,092 covering combining machine.

54. Appropriation No. 91,133, to cover building of additional gutta percha combined machine.

55. Copy of letter from Warth to Goebel.

56. Paper signed by Goebel relating to invention of Warth on use of varnished paper for spot crowns.

57. Letters dated June 29 and July 24, 1933, relating to equipment for coating.

58. Letter from Warth to Goebel, dated July 11, 1933.

59. Contract tendered to Crown Cork & Seal Co. by Waldron Co.

60. Telegram dated August 3, 1933, with reference to Exhibit 59.

64. Copy of Keller patent 1,081,505.

67. Letters addressed to Dr. Warth, headed M. Stover, with reference to experiments.

68. Copy of letter signed A. H. Warth, to J. W. Cleveland of du Pont Co. at Parlin, dated May 11, 1932.

[fol. 2132] 69. Letter dated May 9, 1933, from Warth to John Waldron Co.

70. Letter dated May 25, 1933, from Warth to John Waldron Co.

71. Letter dated June 23, 1933, from Warth to Waldron.

72. Memorandum dated July 28, 1933, signed A. H. Warth.

73. Letter dated August 30, 1920, from A. A. Eisenberg to A. H. Warth.

74. Invoice dated April 13, 1927, from Crown Cork & Seal to Burroughs Bros. Co.

75. Letter dated June 30, 1927, from Warth to Burroughs Bros., and similar letter dated July 1, 1927.

76. Two invoices dated August 17 and September 9, 1927, from Crown Cork & Seal Co. to Macomber Orchard Co.

80. Two photographs showing machine as altered within last week by witness Weisenburg.

84. Copy of letter to Gutmann by Crown Cork & Seal Co. offering license, dated March 21, 1933.

85. Certified copy of certain papers from Interference No. 66,201. (Print only the decision of the Examiner of In-

terferences, dated April 14, 1934, the other papers are contained in Defendant's Exhibit YYYY.)

86. Certified copy of certain papers from Interference No. 60,878.

87. Certified copy of File Wrapper and Contents of Johnson patent 1,852,578.

15. Defendant's Exhibits to be reproduced:

[fol. 2133] A. File Wrapper of Warth patent 1,899,783.

B. File Wrapper of application of John Alberti for patent 1,199,026.

E. Affidavit made by Alberti for Crown Cork & Seal Co.

G. Bills dated November 1 and November 20, 1924, to Ferdinand Gutmann & Company by Nagy for dies.

H. Confirmation order of Beechnut Foil Co., dated December 31, 1924, for .0045 pure tin-foil, produced by witness Maculey.

I. Letter from Beechnut Foil Co., dated January 17, 1925, addressed to Ferdinand Gutmann & Co.

J. Confirmation order dated January 19, 1925, from Beechnut Foil Co. to Ferdinand Gutmann & Co., and invoice of January 22, 1925, covering same.

K. Confirmation orders and invoices from Beechnut Foil Co. to Ferdinand Gutmann & Co., from December 31, 1924, to February 21, 1925, five in number.

L. Letters dated January 24 and January 30, 1929, from Reynolds Metal Co.

M. Letter of March 12 from Reynolds Metal Co. to Ferdinand Gutmann & Co.

N. Invoices from Reynolds Metal Co. to Ferdinand Gutmann Co.

O. Letters of February 8 and February 22, 1929, from Reynolds Metal Co. to Ferdinand Gutmann Co.

P. Bill of August 31, 1928, from Johnson to Ferdinand Gutmann & Co.

[fol. 2134] Q. Four bills from September 17, 1928, to April 30, 1929, for assembling machines from Johnson to Gutmann.

R. Four bills from May 16, 1933, to June 19, 1933, from Johnson to Gutmann for machines.

S. Bill dated July 31, 1928, from Johnson to Gutmann for one tin-foil machine with hopper.

T. Orders from Crown Cork & Seal Co. to Johnson, and copies of invoices from Johnson to Crown Cork & Seal Co. for four machines, from March, 1929 to July 3, 1929.

U. Petition to institute public use proceedings filed by Johnson in Interference Proceedings under patent No. 1,852,578.

V. List of machines sold by Johnson like those in patent 1,852,578.

W. Page 19 of Catalog of A. Johnson Machine Works.

X. Bill of Johnson to Gutmann, dated March 18, 1931.

[fol. 2146] UNITED STATES CIRCUIT COURT OF APPEALS FOR THE SECOND CIRCUIT, OCTOBER TERM, 1936

Argued Oct. 6, 1936. Decided Dec. 14, 1936

No. 89

CROWN CORK & SEAL COMPANY, INC., Plaintiff-Appellant and Appellee,

v.

FERDINAND GUTMANN & COMPANY, Defendant-Appellant and Appellee

Appeal from the District Court of the United States for the Eastern District of New York

Before Manton, L. Hand, and Swan, Circuit Judges

Suit in equity by Crown Cork & Seal Company, Inc., charging infringement of six patents, and counterclaim by the defendant charging infringement of a patent owned by it. From a decree which held three of the plaintiff's patents valid and infringed, dismissed the complaint as to the others, and also dismissed the counterclaim, both parties have appealed. Decree modified.

For the opinion below, see (D. C.) 14 F. Supp. 255.

Gifford, Scull & Burgess, of New York City (George F. Scull, of New York City, and John J. Darby, of Washington, D. C., of counsel), for plaintiff.

Hauff & Warland, of New York City (William E. Warland and Francis H. Warland, both of New York City, of counsel), for defendant.

SWAN, Circuit Judge:

The patents in suit relate to a type of bottle closure known as a "spot crown cap" and to methods of making such caps. The plaintiff has appealed in respect to Warth patents No. 1,899,783 (claim 4) and No. 1,956,481 (claims 6 and 16), which were held invalid.[1] McManus patent No. 1,339,066 (claims 3 and 8) and Warth patents reissue 19,117

[1] Warth patent No. 1,899,762 (claims 7 and 9) was also held invalid, but no appeal has been taken as to this.

(claims 1 and 3) and No. 1,967,195 (claims 1, 2 and 3) were held valid and infringed, and as to these the defendant has appealed. The defendant has also appealed from dismissal of its counterclaim for noninfringement of Cohn patent No. 1,921,808.

Long prior to the patents in suit the bottling art was familiar with crown caps which had no center spot. Such caps were formed of a thin metal shell, containing a cushion disc of natural cork or composition cork adapted to seal the mouth of the bottle when the cap was pressed into engagement with its lip. There were disadvantages, however, in having the contents of the bottle come into contact with the cork disc. Consequently the practice developed of applying to the face of the cork disc a thin sheet of material, such as tin foil or glazed paper, impermeable to the liquid contents of the bottle. This may take the form of an "overall" facing, or of a partial or "spot" facing. In the "overall," the protective foil or paper covers the entire face of the cushion disc. Such a form of crown cap is satisfactory when the contents of the bottle are not under gas pressure, but is likely to result in leakage in the case of pressure beverages. In spot crown caps the protective facing of the cork cushion is a "spot" or disc of such diameter as to extend only part way over the lip of the bottle and permit the rest of the lip to make contact with the cork cushion, thus forming a more perfect seal and at the same time [fol. 2147] preventing the liquid from touching the cork. The chief difficulty in the manufacture of such caps has been in affixing the spot to the cork disc. It must be accurately centered and firmly attached. From 1914 the White Rock Company has used a tin foil spot which is mechanically attached to the cork disc. The patents in suit, however, relate to spots which are adhesively attached by a "fusible binder"; that is, the adhesive must be one which is softened and made sticky by heat, as distinguished from one which has to be moistened to be applied. For the commercial success of spot crown caps it is essential that they be manufactured cheaply and this involves rapidity of assemblage. Operating under the patents in suit the plaintiff applies spots to crowns at the rate of 500 per minute for each operating unit and is able to sell the entire cap at a price of about six for one cent. Its sales amount to about 9 million gross per year.

1. With this brief preliminary exposition we may turn to the patents in suit, of which the first is McManus patent No. 1,339,066, granted May 4, 1920, upon an application filed November 17, 1915. Claims 3 and 8 were in suit and were held valid and infringed. This patent describes and claims a center spot crown cap as an article of manufacture, and the claims in suit require that the spot be united with the cork or composition cushion disc "by means of a fusible binding medium." The specifications explain that crown caps without the center spot were old and were subject to disadvantages because the liquid came into contact with the cork or cork-composition disc. Apparently McManus conceived that his inventive thought was the idea of overcoming these objections by adding the center spot. He was not, however, the originator of spot crown caps. As already noted, the White Rock Company began in 1914 to use mechanically attached spots. DeMuth's British patent No. 16075, issued in July, 1914, upon an application dated July 12, 1913, shows a liquid-resisting spot secured to the cork disc "by cementing or in any other appropriate manner." The United States patent No. 1,199,026 issued in 1918 to Alberti, whose application was dated October 3, 1914, also discloses a spot cemented to the cork disc. Alberti used a moist cement, albumen, which was coagulated and caused to stick by the subsequent application of heat and pressure. Concededly the only new feature, if any, which McManus added was the use of a "fusible binding medium" instead of a moist adhesive. As he points out, a fusible binder between the tin cap and cork cushion was already old, and preferably he specifies the same binding material to attach the spot. Moreover, the Koch patent No. 1,238,156, issued in 1917 on an application filed September 21, 1915, shows a fusible binder, gutta percha, as the medium for attaching the "overall" type of spot. Thus McManus is reduced to the proposition that, although heat fusible adhesives were old for securing discs to caps, and "overalls" to discs, his was the first disclosure with respect to fastening a center spot by such an adhesive. It is impossible to believe that it required ingenuity worthy of the name of invention to take the step of using upon the "spot" the same adhesive used upon the "overall" coating. Nor was this idea immediately seized upon as the solution of an existing problem. Rather the problem, as the history of the development of the industry shows, was to perfect a

machine that would operate with sufficient accuracy and speed to render manufacture commercially successful. McManus himself, though attempting to manufacture spot crown caps, did not utilize commercially the idea of a fusible binder until about 1926. Our conclusion is that claims 3 and 8 are invalid for lack of invention.

2. Warth "Paper Spot" patent No. 1,899,783. This was granted February 28, 1933 on a divisional application filed October 31, 1930, of a parent application filed May 5, 1929. Only claim 4 was in suit; it was held invalid. This claim calls for a crown cap with a center spot "of hard, high-gloss paper having a varnished outer surface" and fastened to the cushion by gutta percha. For high pressure, acidulated beverages, such as ginger ale, tin foil spots were not suitable, because the acid would eat through the foil, thus permitting the beverage to acquire a corky taste and to lose pressure through the pores of the cork or composition cushion. The object of the patent was to avoid the ill effects of the use of tin foil. The only "problem" was to select a facing for the cushion which would withstand the attack of acidulated liquids and be not too thick to bend when pressure was applied in closing the cap [fol. 2148] upon the bottle. A paper facing, varnished to prevent absorption, was old in the art. Smith's patent No. 983,319, of 1911, discloses the use of a varnished manila paper for an "overall" cap-facing. The McManus patent already discussed recommended for the "spot" facing "a hard parchment paper, or any other paper so treated as to make it non-absorbent." The Lange patent No. 1,657,802, issued in 1928, application filed December 16, 1924, used a varnished paper to make a cover for preserve jars and the like. Warth testified that it took experimentation over a considerable period of time to select a paper of the right toughness, density and thinness and a varnish which would impart no flavor to the bottled beverage, but with this prior art we can see no room for invention in what he did, and we agree with the District Court that claim 4 of the Warth paper spot patent shows no novelty or invention and is invalid.

3. Warth patent No. 1,956,481, granted April 24, 1934, application filed June 16, 1933. Claims 6 and 16 were in suit and were held invalid. These claims call for a spot crown cap in which the spot is stuck to the cushion by a

thermoplastic adhesive composed of nitrocellulose and a resin, which is a better adhesive than the conventional gutta percha. Both the plaintiff and the defendant use as an adhesive a preparation manufactured and sold by the du Pont Company under the name "4620." This came on the market in 1932, and became the medium adopted by both litigants, the defendant's commercial use having started in June or July, 1933, and the plaintiff's about one year later. Concededly it is an anticipation of the patent in suit, unless Warth can carry back his date of invention and reduction to practice. This he attempts to do, contending that his date of conception was the fall of 1926 and his reduction to practice at least as early as January, 1932. It is doubtless true that Warth was experimenting in 1926 with nitrocellulose, but he plainly had not then reached the goal, for, according to his own testimony, the mixture he had achieved "was not as good as gutta percha." Not until 1930 did Warth tell McManus of the possibility of using a nitrocellulose-resin cement, and he had not then worked out any formula for the mixture. About a year later McManus asked Weisenberg to work on the idea, without telling him of Warth's previous attempts to find the right mixture. Then in January, 1932, the du Pont Company delivered to the plaintiff a can of "4620" to be tried out as an adhesive for spot crown caps. Warth instructed his secretary to see if it would work, saying, "That is something I have been trying to find, as you know, for a long time." It is possible that Warth had given some ideas to the du Ponts, but it seems plain that they and not he worked them out. The above-quoted statement to Warth's secretary is wholly inconsistent with the contention that "4620" was his own work. So also are the fact that he made an affidavit in December, 1932, speaking of gutta percha as the best of the known adhesives, and the fact that between the fall of 1926 and October 30, 1930, he filed no less than five patent applications, each of which sang the praises of gutta percha and made no mention of nitrocellulose and resin. Under the severe rules applicable to carrying back the date of an invention, Warth has failed to carry the burden of doing so, and we hold that patent No. 1,956,481 was anticipated by "4620."

4. Warth Reissue No. 19,117 dated March 20, 1934. This is a reissue of patent No. 1,788,260 which was applied for

January 7, 1927, and granted January 6, 1931. Application for reissue was filed January 23, 1934. Claims 1 and 3 were in suit and were held valid and infringed. These are process claims for a method of manufacturing spot crown caps. The "spot" material is in the form of a strip of tin foil or liquid-resisting paper, coated on the under side with a thermoplastic adhesive. The patent requires drawing the strip over a die and under a punch, cutting the spot from the strip by the punch, which positions the spot upon the cork disc, "and upon assembly applying simultaneously to the spot pressure and sufficient heat to render the adhesive tacky, thereby causing the spot to adhere" to the cork disc, and then permitting the adhesive to cool and harden. Claim 3 merely adds that the cooling step shall occur "while subjecting the assembled unit to pressure." It is contended by the defendant that, if the claims can be sustained as valid at all, they must be limited to mean that the heat and pressure are applied by the cutting punch; and, if so lim- [fol. 2149] ited, the defendant does not infringe, for the defendant uses a cold cutting punch [2] which positions the spot on a cork disc previously heated sufficiently to cause the spot to adhere while the cap is carried to the next stage, where a hot plunger applies heat and pressure. We think this contention is well taken.

The parent application originally contained a paragraph which disclosed the preheating step and had claims sufficiently broad to cover it, but on December 3, 1930, the preheating passage was stricken from the specifications, all claims were canceled, and the present first claim was substituted. That left the specifications with the statement that the preferred method of applying the spot material to the cap is "to utilize, at the time of assembly, both heat and pressure," and that "the punch 20 may be maintained at an elevated temperature, as by means of a burrer 23," and left the claim, in so far as it referred to heating, as follows: "And upon assembly applying simultaneously to the spot

[2] Although we refer to the cutting punch as "cold," it actually gets heat by radiation from the adjacent "preheater" and "post heater" plungers so that its temperature may be as high as 140° F., but this is not enough to make the adhesive sufficiently tacky to adhere to the cork unless the latter has been preheated.

pressure and sufficient heat'' to cause the spot to adhere. This was the form in which the patent was granted. It clearly means *applying* the heat at the time of pressure, not pressure by a cold punch on an already heated crown. Further considerations lead to the same conclusion, namely that the claims require the heat and pressure to be applied by the cutting punch. In the plaintiff's ''slide machine,'' which goes back to 1917, a strip of spot material and a strip of adhesive (gutta percha) were drawn beneath the punch which descended to cut the spot and deposit it upon a slide member, which then passed under a heated plunger with a suction device which sucked up the spot and held it until a cap containing the cork disc passed beneath, when the plunger descended, pressing the spot upon the cork. While the mechanism of the slide machine is quite different from that of the machine by which Warth's process is applied, it must be remembered that his patent is not for the machine but for a method of manufacture involving cutting the spot and causing it to adhere to the cork disc by the application of heat and pressure. To read the claims of the reissue patent to mean a cold punch to cut the spot and a hot plunger applied later to fasten it to the cork disc would make them invalid under the old ''slide machine.'' To read them to mean a cold punch which positions the spot upon a preheated cork would be inconsistent with the fact that the preheating specification was deliberately divided out and later claimed in Warth's ''preheating patent'' hereafter to be discussed. Consequently we conclude that the defendant's method of manufacture does not infringe claims 1 and 3 of reissue No. 19,117.

5. Warth ''preheating'' patent No. 1,967,195. This was granted July 17, 1934, upon a divisional application filed April 4, 1933. Claims 1, 2, and 3 are in suit and were held valid and infringed. They are process claims for the preheating method already referred to. The cork disc in the cap is heated before it passes under the cutting punch which positions the spot on the cork. The heat of the cork makes the adhesive of the spot tacky, so that the pressure of the cutting punch causes it to adhere. At the next step a heated plunger is pressed down on the spot; then it is passed under a cold plunger and kept under pressure until the adhesive has cooled. Each of the claims in suit calls for ''heating the pads in the caps''; that is, for preheating

of the cork disc before the spot is positioned upon it. This is the feature which distinguishes the patent from the prior reissue. It is the process used by both the plaintiff and the defendant. The defendant infringes, if the claims are valid. We think they are invalid for laches in filing the application for them. Webster Co. v. Splitdorf Co., 264 U. S. 463, 44 S. Ct. 342, 68 L. Ed. 792.

The parties are in dispute as to the effective date of application for the claims in suit, the defendant contending for the day the claims were actually filed, namely, April 4, 1933, and the plaintiff for the date of the parent application, namely, January 7, 1927. As already explained, the reference to preheating in the parent application was [fol. 2150] stricken out on December 3, 1930. Previously, on November 7, 1930, Warth had filed a divisional application No. 494,201 to which he had transferred the preheating method; it claimed only the spot material strip as an article of manufacture. As we have previously shown, Warth's patents No. 1,788,260 and reissue 19,117 contained no claims broad enough to cover preheating. Hence there was no claim for the preheating method on file in the Patent Office from December 3, 1930, until April 4, 1933, when Warth applied by his second divisional application for the preheating patent. The disclosure, however, had been continuously on file since January 7, 1927; and so the plaintiff contends that it is entitled to that filing date. We do not so understand the law, as laid down in Webster Co. v. Splitdorf Co., 264 U. S. 463, 471, 44 S. Ct. 342, 344, 68 L. Ed. 792. Prima facie the two-year time limit applies to divisional applications, and an applicant who waits longer before claiming the invention disclosed in his application must justify his delay by proof of some excuse. No such excuse appears here. Had Warth chosen to retain in his parent application broad generic claims which might cover the preheating method, then indeed the Splitdorf rule might not be applicable. Carson v. American Smelting & Refining Co., 4 F. (2d) 463, 470 (C. C. A. 9). The delay would be excused since a patentee is not to be held at fault for failure to have divided his claims at an earlier date, merely because he might have, when instead he had elected to prosecute the broader claims of his original application. Hartford-Empire Co. v. Nivison-Weiskopf Co., 58 F. (2d)

701 (C. C. A. 6). But, in the case at bar, for a period of more than two years Warth apparently did not wish to claim the preheating method, having deliberately canceled the preheating specification from his original application and shaped his claims so as to exclude it and his patent having been granted January 6, 1931. He made no claim for preheating until more than two years thereafter, namely, April 4, 1933. In the meantime a patent containing claims for the preheating method had been granted to Johnson on April 5, 1932, and it was Warth's discovery of this fact which stirred him to action. As in the Splitdorf Case, had it not been for this competitor, Warth might never have considered the subject worth claiming as an invention. These circumstances invite operation of the two-year limitation designed to protect the public against obtaining in effect an extension of a patentee's monopoly by apathy and unexcused delay in bringing forward by divisional or reissue applications claims broader than those originally sought. See Westinghouse Electric & Mfg. Co. v. Jeffrey-DeWitt Insulator Co., 22 F. (2d) 277 (C. C. A. 2). Wagenhorst v. Hydraulic Steel Co., 27 F. (2d) 27, 29 (C. C. A. 6); Otis Elevator Co. v. Atlantic Elevator Co., 47 F. (2d) 545, 549 (C. C. A. 2); Wirebounds Patents Co. v. Saranac Automatic Machine Corp., 65 F. (2d) 904 (C. C. A. 6); compare Phelan v. Green, 71 F. (2d) 298, 301 (Cust. & Pat. App.).

6. By counterclaim the defendant charged infringement of patent No. 1,921,808 to Cohn. The counterclaim was dismissed on the ground of noninfringement. This was plainly right; the plaintiff had neither infringed nor threatened to do so.

For the reasons stated in the foregoing opinion, the plaintiff should have been denied relief upon all its patents. The interlocutory decree is modified, and the cause remanded, with directions to dismiss the bill of complaint.

[fol. 2151] UNITED STATES CIRCUIT COURT OF APPEALS FOR THE SECOND CIRCUIT, OCTOBER TERM, 1936

Argued Oct. 6, 1936. Decided Dec. 14, 1936

No. 89

CROWN CORK & SEAL COMPANY, INC., Plaintiff-Appellant and Appellee,

v.

FERDINAND GUTMANN & COMPANY, Defendant-Appellant and Appellee

Appeal from the District Court of the United States for the Eastern District of New York

Before Manton, L. Hand, and Swan, Circuit Judges

MANTON, Circuit Judge (dissenting):

The District Judge entered a decree for the plaintiff holding the McManus patent No. 1,339,066, Warth patents reissue No. 19,117 and No. 1,967,195 valid and infringed. He dismissed the complaint on the merits as to the Warth patents No. 1,899,782, No. 1,899,783, and No. 1,956,481. I agree with his reasons and conclusions which are fully and ably stated in Crown Cork & Seal Co. v. Gutman & Co. (D. C.), 14 F. Supp. 255.

I accordingly dissent from the modification of the decree.

[fol. 2152] UNITED STATES CIRCUIT COURT OF APPEALS, SECOND CIRCUIT

At a Stated Term of the United States Circuit Court of Appeals, in and for the Second Circuit, held at the United States Court House, in the City of New York, on the 21st day of December, one thousand nine hundred and thirty-six.

Present: Hon. Martin T. Manton, Hon. Learned Hand, Hon. Thomas W. Swan, Circuit Judges.

OCTOBER TERM, 1936.

No. ——

CROWN CORK & SEAL COMPANY, INC., *Petitioner*,

v.

FERDINAND GUTMANN CO., INC., *Respondent*.

PETITION FOR A WRIT OF CERTIORARI TO THE CIRCUIT COURT OF APPEALS FOR THE SECOND CIRCUIT.

TO THE HONORABLE CHIEF JUSTICE AND ASSOCIATE JUSTICES OF THE SUPREME COURT OF THE UNITED STATES:

Your petitioner, Crown Cork & Seal Company, Inc., plaintiff, respectfully prays for a writ of certiorari to the Circuit Court of Appeals for the Second Circuit to review a judgment of that court rendered on January 22, 1937.

SUMMARY AND SHORT STATEMENT.

This action was brought by petitioner to enjoin infringement of two* Letters Patent, namely, Warth Reissue No. 19,117, dated March 20, 1934 (R., p. 711), hereinafter identified as the "parent" patent, and Warth patent No. 1,967,195, dated July 17, 1934 (R., p. 716), hereinafter identified as the "divisional" patent. The patents cover methods for applying a small disc of foil or paper, known as a "center spot", to the cork cushion discs of crown caps used for sealing high pressure beverages, such as beer and ginger ale. The center spot serves to protect the cork cushion from the sealed liquid in the manner illustrated in the sketch appended to the brief.

The District Court for the Eastern District of New York (Campbell, J.,) found both patents valid and infringed, 14 F. Supp. 255 (R., pp. 2047, 2072; decree p. 2107). The Circuit Court of Appeals for the Second Circuit (Manton, J., dissenting) reversed the decree, holding (R., pp. 2146, 2150) that the parent patent was not infringed and that the divisional patent was invalid because of laches in filing the application. The opinion of the Court of Appeals is reported at 86 F. (2d) 698.

The application for the parent patent was filed on January 7, 1927 (R., p. 1485) and matured into patent No. 1,788,260, dated January 6, 1931. Before the issuance of the parent patent, a second application had been filed (R., p. 1948) with the same disclosure. While the second application was pending, a patent to one Johnson, No. 1,852,578, issued on April 5, 1932 with claims covering specific subject-matter *disclosed* in the Warth original and second applications, but not then *claimed* in the pending second application. From the second application, Warth carved a divisional application, which resulted in the divisional patent in suit, and copied therein the claims of the Johnson

*Three other patents before the Court of Appeals are not involved in this petition.

patent* two years and four months after the parent Warth patent had issued. There is no issue here as to the propriety of filing the division instead of inserting the claims by amendment in the then pending second application.

In an interference with this Johnson patent, the Patent Office held the Warth divisional application entitled to the filing date of the parent Warth patent. This was in accord with the practice of the Patent Office for the past fifty years, as approved by this Court in *Chapman v. Wintroath* (252 U. S. 135). The claims of the Johnson patent were accordingly awarded to Warth as the prior inventor and are now the claims of the Warth divisional patent here in suit.

There had been no adverse public use or printed publication or other intervening right for more than two years before these claims were asserted by Warth in his divisional application.**

Decision of Circuit Court of Appeals

The Circuit Court of Appeals overruled the holding of the Patent Office, which followed its practice of over fifty years, and the holding of the District Court (R., p. 2101)

*Johnson is not involved in this suit. The Johnson patent claims were copied within a year after the patent had issued and therefore within the two years allowed by *Chapman* v. *Wintroath,* 252 U. S. 135.

**The Court of Appeals referred to the issuance of the Warth parent patent more than two years before the divisional patent claims were asserted, but the patent contained no description of the method of the Warth divisional patent and hence was not a printed publication. The Court of Appeals also referred to the Johnson patent, but this issued less than a year before the claims were asserted by Warth and hence is not a bar under the rule of this Court in the *Chapman* case, *supra.* Defendant's use of the invention was also urged as being more than two years prior to the Warth divisional application, but was found by the District Court not to anticipate (antedate) the filing date of the Warth divisional patent (R., p. 2100) and this finding was not disturbed by the Court of Appeals although defendant strenuously urged that such finding was error.

and held that the delay of two years and four months in asserting specific claims in Warth's divisional application invalidated such claims in the absence of a legal excuse, notwithstanding that the subject-matter of said claims had not been disclosed in any patent, publication or prior public use for two years or more before such claims were inserted. The Court said (R., p. 2153):

> "The disclosure, however, had been continuously on file since January 7, 1927 (the filing date of the parent patent) and so the plaintiff contends that it is entitled to that filing date. We do not so understand the law, as laid down in Webster v. Splitdorf, 264 U. S. 463, 471, 44 S. Ct. 342, 343, 68 L. Ed. 792. Prima facie the two year limit applies to divisional applications, and an applicant who waits longer before claiming the invention disclosed in his application must justify his delay by proof of some excuse. No such excuse appears here."

The Court of Appeals (R., p. 2151) found that the Warth patent application originally "had claims sufficiently broad to cover it" (the specific subject-matter of the Warth divisional patent) but that such claims were cancelled on December 3, 1930. This was two years and four months before Warth again asserted claims to the specific subject-matter of his divisional patent. During this interval no intervening bar had arisen; see footnote, p. 3 *ante*.

Conflict between Circuit Court of Appeals in case at bar and other Circuit Courts of Appeals.

This interpretation of *Webster* v. *Splitdorf*, 264 U. S. 463, by the Circuit Court of Appeals for the Second Circuit directly conflicts with the interpretation of that case by the Circuit Courts of Appeals for the First Circuit and for the Sixth Circuit. Each of these last-named Courts has held the doctrine of the *Webster* case to apply only where there has been an adverse public use, a printed publication, or other intervening right more than two years

before the claims were presented. **See the quotations in the brief, pp. 21, 23, from the following decisions:**

Utah Radio Corp. Products v. *Boudette,* 78 F. (2d) 793 (C. C. A. 1st).

Wagenhorst v. *Hydraulic Steel Co.,* 27 F. (2d) 27 (C. C. A. 6th).

Wirebounds Patents Co. et al. v. *Saranac,* 37 F. (2d) 830 (C. C. A. 6th).

Furthermore, the interpretation of the *Webster* case by the Court of Appeals for the Second Circuit conflicts with the practice of the Patent Office for over fifty years. The Patent Office had always accorded a divisional application the benefit of the filing date of the parent application for all subject-matter common to the two applications, whether such subject-matter had been claimed in the parent application or not. The only exception, regardless of the lapse of time in presenting the claims in the divisional case, had been where the rights of others intervened more than two years before the claims were presented. This practice by the Patent Office has been in accordance with the decisions of this Court in *Chapman* v. *Wintroath* and *Webster* v. *Splitdorf, supra,* by analogy to the fundamental statute* which prohibits the issuance of a patent to the first inventor only if there has been a public use, printed publication

*Sec. 4886. (U. S. C., title 35, sec. 31) Any person who has invented or discovered any new and useful art, machine, manufacture, or composition of matter, or any new and useful improvements thereof, or who has invented or discovered and asexually reproduced any distinct and new variety of plant, other than a tuber-propagated plant, not known or used by others in this country, before his invention or discovery thereof, and not patented or described in any printed publication in this or any foreign country, before his invention or discovery thereof, or more than two years prior to his application, and not in public use or on sale in this country for more than two years prior to his application, unless the same is proved to have been abandoned, may, upon payment of the fees required by law, and other due proceeding had, obtain a patent therefor.

or sale more than two years before the application for patent.

Obviously, this conflict in interpretation of the decision in *Webster* v. *Splitdorf* should be resolved by this Court. We submit that the interpretation by the Court of Appeals for the Second Circuit is not correct, because it establishes a bar to the grant of a patent not embodied in the fundamental statute. As this Court held in the *Chapman* case, *supra,* any bar established by a Court to the grant of a patent should be reconcilable with that statute and no Court can disregard any statutory provisions in respect to these matters "on the ground that, in its judgment, they are unwise or prejudicial to the interest of the public." *United States* v. *American Bell Telephone Co.,* 167 U. S. 224, 247.

The conflicting interpretations of the *Webster* case by the several Circuit Courts of Appeals is further emphasized by the decision of the Circuit Court of Appeals for the Eighth Circuit in *Hartford-Empire Company* v. *O'Bear-Nester Glass Co.,* 39 F. (2d) 769, which holds that if claims are presented in a divisional application more than two years after the filing of the parent application and a patent has issued to another at any time prior to the presentation of the claims, the claims are barred. **See the quotation from the Hartford decision in the brief, p. 24,** *infra.*

Under this rule the Johnson patent, issued *less than a year* before the Johnson patent claims were presented in the Warth divisional application, would invalidate the Warth divisional patent claims, although this Court in the *Chapman* case held that the claims of such a patent may be made at any time within two years.

Consequently, the Court of Appeals for the Eighth Circuit follows more closely the interpretation of the *Webster* case by the Court of Appeals for the Second Circuit in the case at bar than the interpretation by the Courts of Appeals for the First and Sixth Circuits. Yet, the Court of Appeals for the Eighth Circuit recognized the confusion when it said **(at 775):**

"The point is one with which, and with its variables upon varying facts, the courts have *had much trouble.** The law is yet seemingly in the process of crystallization as to what shall be the final rule. (Citing: *Chapman* v. *Wintroath, Webster* v. *Splitdorf, supra,* and other cases.)"

A second question presented and as to which the decision of the Circuit Court of Appeals in the case at bar conflicts with another Circuit Court of Appeals, is whether, assuming an excuse is required, the fact that the claims of the Warth parent patent were intended and believed to, and apparently do, cover the subject-matter of the Warth divisional patent claims, is an excuse for the lapse of over two years in presenting the divisional patent claims.

The Court of Appeals, reversing the District Court, held that, although Warth had claimed broadly the invention of the divisional patent prior to December 1930 in the parent application, the claims of his parent patent did not cover the divisional patent subject-matter, and that the subject-matter was not again claimed until two years and four months thereafter in the application for the divisional patent.

It is settled that more than two years lapse or delay, even after an intervening right may be excused "by special circumstances which show it to have been not unreasonable" (*Webster* v. *Splitdorf, supra*). The Courts are also in agreement that, if a parent patent has claims broad enough in scope to include a specific form of the invention, then more than two years delay in asserting, in a divisional application, claims limited to such specific form is not unreasonable and is excused. The Court of Appeals for the Second Circuit so held (R., p. 2153).

In the case at bar, the "special circumstance" offered as an excuse, is that the claims of the parent Warth patent *were intended to and, on their face, are* broad enough to

*Italics ours throughout unless otherwise stated.

cover the specific form of the invention claimed in the divisional patent. And the plaintiff believed they did. Moreover, the District Court held that the parent patent claims are of sufficient breadth to cover the subject-matter of the divisional patent claims. (R., p. 2082)

Such an excuse for delay was accepted by the Court of Appeals for the Sixth Circuit in the *Wagenhorst* case,* *supra,* but was rejected by the Court of Appeals for the Second Circuit in the case at bar, although petitioner urged that as an excuse for delay. Instead, by an arbitrary reading of a limitation into the claims** of the Warth parent patent, the Court so limited the scope of those claims as to exclude the subject-matter of the divisional patent and then held that the claims thus interpreted presented no excuse for delay.

Other courts have held that delay in presenting claims is excused and abandonment is negatived when, as here, an inventor believed, mistakenly or not, that he had broadly covered the invention by an earlier filed application. See: *McGrath* v. *Burke* (Court of Appeals, D. C.) 12 F. (2d) 161, 162; *MacLaren* v. *Stoetzel* (C. C. P. A.) 38 F. (2d) 125, 129. These cases are in point, since the question involved was, as in the case at bar, whether the applicant for patent exercised diligence in presenting claims.

The refusal of the Court of Appeals for the Second Circuit to excuse the delay in presenting the claims of the divisional patent directly conflicts with the decision of the

---

*In the *Wagenhorst* case, the Court, excusing delay in presenting claims in a divisional application because of the apparent breadth of claims in the parent application, said (at 31): "It may be said, with some certainty as to original claim 2, and with some probability as to claims 1 and 3, that, if granted, they would have *seemed* to cover defendant's later structure, *and might or might not have been construed in that way.*"

**This was done notwithstanding the rule of this Court in *Altoona* v. *American Tri-Ergon,* 294 U. S. 477, 487, that a claim should not be construed "by reading into it parts of the specifications * * which the patentees failed to include in it."

Court of Appeals for the Sixth Circuit in the *Wagenhorst* case wherein it was held that it is the *seeming* scope of the claims of the parent application which is the determining factor, regardless of whether such claims might or might not be finally construed broadly.

Obviously, this conflict of decisions between the two Circuit Courts of Appeals should be resolved by this Court. It is submitted that the ruling of the Court of Appeals for the Sixth Circuit is correct and that under the same it was reasonable* for Warth to rely on the apparent and intended scope of the parent patent claims, regardless of the final limited construction given to such claims by the Court of Appeals for the Second Circuit.

THE QUESTIONS PRESENTED.

1—Does this Court's decision in *Webster* v. *Splitdorf* mean that, *even in the absence of intervening adverse rights,* an excuse must be shown for a lapse of more than two years in presenting claims in a divisional application regularly filed and prosecuted in accordance with the Patent Office rules?

2—Where there has been more than two years delay in asserting specific claims in a divisional application, is it an excuse for the delay that there were claims in the parent patent which, on their face, covered and were reasonably believed to cover, the subject-matter of the divisional claims, even if a Court later interpreted the parent patent claims not to cover such subject-matter?

Public Importance of Questions Raised.

Because of the conflicting interpretations of this Court's decision in the *Webster* case, there is great confusion as to

*The finding of the District Court (R., p. 2082) that the claims of the parent patent are broad enough to include the specific form of the invention defined in the divisional patent claims is evidence of the reasonableness of Warth's conduct.

the rights and duties of applicants for divisional patents. Divisional applications represent a very large percentage of cases prosecuted before the Patent Office* and divisional patents a corresponding large percentage of those granted. This Court, in the *Chapman* and *Webster* cases, has already recognized the importance of divisional applications and patents and that they should be favored "designed as they are to secure the patent to the first discoverer".

Under the rule established by the Court of Appeals for the Second Circuit in this case, the practice of the Patent Office with respect to claims presented in divisional applications is incorrect, and numerous invalid divisional patents are being granted. It is vital that the public know to what extent these patents are enforceable.

Moreover, the confusion which has arisen from the conflicting interpretation of this Court's decision in the *Webster* case by the Patent Office and the various Courts of Appeals has given rise to great uncertainty as to (a) under what circumstances the two year limit shall be applied, and (b) when the limit begins to run.

The exception in the *Webster* case to the rule of this Court that divisional applications are entitled to the filing dates of parent applications for any matter disclosed in the latter, whether claimed or not, should be made definite in the interest of the public and inventors alike.

As to the secondary question, this Court has never decided whether facts such as presented here are an excuse for a delay in presenting claims in a divisional application. The Court of Appeals for the Sixth Circuit in the *Wagenhorst* case has held that the presence of claims in the parent application, on which the patentee reasonably relied as covering the invention, constitutes an adequate excuse for

---

*For example, in 1934 and 1935, the last years records were maintained by the Patent Office, approximately every eighth applicant for patent was required to file divisional applications to protect his full disclosure. In 1934, examination of applications resulted in 7162 requirements for divisions and in 1935, 7609 requirements.

delay. The Court of Appeals for the Second Circuit in the case at bar has held to the contrary. Manifestly, it is of great importance that this conflict be resolved by this Court.

It is to the interest of both inventors and the public that divisional applications be favored. This Court's statement in the *Chapman* case, *supra,* that divisional applications are not to be treated in a "hostile spirit", is a recognition of their importance.

Encouragement of divisional applications induces inventors to file disclosures of their inventions promptly and completely. As this Court said in the *Chapman* case, divisional applications facilitate the determination of the first inventor to whom the patent should issue under the statute.

It is an everyday occurrence for an inventor, in his aim to file a full disclosure, to describe more than a single invention. Not infrequently, the inventor is unaware at the time of filing that certain phases of his disclosure are inventions and must be separately and specifically claimed. It is not unusual for an inventor to realize only more than two years after filing his application the necessity for *specific* claims to certain phases of his original disclosure. Before the rule by the Circuit Court of Appeals for the Second Circuit in this case, an inventor was entitled to claim at any time, either in his original patent or in a division, anything he disclosed, whether or not he initially recognized it as an invention or the necessity for claiming it specifically, unless there was an intervening adverse public use, patent or printed publication more than two years before the assertion of the claims.

The new rule laid down in the case at bar penalizes the inventor who discloses more than a single invention in his original application, and thus discourages the complete and prompt filing heretofore induced by the benefits accorded divisional applications. By withholding such disclosures the inventor incurs only the risk that some bar under the statute (Sec. 4886 U. S. C., title 35, sec. 31, p. 5, *ante*) may arise.

By filing them, he incurs, under this rule, the obligation of continuously claiming *specifically* everything initially described under the penalty that, if he overlooks or for any reason fails to claim some phase of his disclosure for a period of more than two years, prima facie he is not entitled to a patent thereon, whether there has been an adverse intervening right or not. Never before has such a drastic rule been laid down with respect to divisional applications.

REASONS RELIED ON FOR THE ALLOWANCE OF THE WRIT.

Your petitioner respectfully prays that the writ be allowed for the following reasons:

1—Because the decision of the Circuit Court of Appeals for the Second Circuit is in direct conflict with decisions of the Circuit Court of Appeals of the First Circuit in *Utah Radio Corp. Products* v. *Boudette*, 78 F. (2d) 793, and of the Circuit Court of Appeals for the Sixth Circuit in *Wagenhorst* v. *Hydraulic Steel Co.*, 27 F. (2d) 27, and *Wirebounds Patents Co. et al.* v. *Saranac*, 37 F. (2d) 830, and the decisions of the Sixth Circuit are in conflict with the decision of the Circuit Court of Appeals of the Eighth Circuit in *Hartford-Empire Company* v. *O'Bear-Nester Glass Co.*, 39 F. (2d) 769, which to an extent supports the decision of the Court of Appeals in the case at bar. See *supra*, pp. 4, 6.

2—Because the decision of the Circuit Court of Appeals for the Second Circuit misinterprets and misapplies the decision of this Court in *Webster Co.* v. *Splitdorf*, 264 U. S. 463. See *supra*, pp. 4, 6.

3—Because the decision of the Circuit Court of Appeals for the Second Circuit overturns the practice of the Patent Office, as it has existed for more than fifty years, with respect to the right of an applicant to present claims in a divisional application. See *supra*, p. 5.

4—Because the public interest and the interest of inventors require that the rights and duties in respect to the presentation of claims in divisional applications and the rule

of law on the subject be defined and explained so that the Patent Office and the courts of the several circuits may be instructed in the application of the rule to particular states of facts to the end that reasonable uniformity of decision among the circuits may be restored. See *supra*, pp. 9, 11.

PRAYER.

WHEREFORE, your petitioner respectfully prays that a writ of certiorari be issued to the United States Circuit Court of Appeals for the Second Circuit to the end that this cause may be reviewed and determined by this Court; that the decree of the Circuit Court of Appeals for the Second Circuit be reversed; and that petitioner be granted such other and further relief as may be proper.

BRIEF IN SUPPORT OF PETITION FOR WRIT OF CERTIORARI.

Opinions of Courts Below.

The opinion of the District Court (Campbell, J.,) is found at pages 2071 and 2090 of the record and is reported in 14 F. Supp. pp. 264 and 270.

The opinion of the Circuit Court of Appeals (Circuit Judges Manton, L. Hand and Swan, Judge Swan writing, Judge Manton dissenting) is reported at 86 F. (2d) 698, 701 and appears at page 2150 of the record.

Jurisdiction.

The judgment of the Circuit Court of Appeals was entered December 21, 1936 (R., p. 2156). Petition for rehearing was denied January 22, 1937 (R., p. 2157). Extension of thirty days from April 22, 1937 for filing petition for certiorari was granted by Mr. Justice Stone on April 8, 1937 (R., p. 2159).

The Statute giving jurisdiction is Section 240 (a) of the Judicial Code (28 U. S. C. Sec. 347).

Statement of the Case.

The foregoing petition contains a summary of the material facts necessary to an understanding of the reasons relied upon for the allowance of the writ, as well as a statement of the questions involved in the case.

Specification of Errors.

1. The Circuit Court of Appeals for the Second Circuit erred in finding and holding that a two year time limit for presenting claims in a divisional application, as announced by this Court in *Webster Co.* v. *Splitdorf Co.*, 264 U. S. 463, is applicable in the present case and in the absence of adverse public use, patenting or publication more than two years before the presentation of the claims.

2. The Circuit Court of Appeals for the Second Circuit erred in ignoring the apparent and intended breadth of the claims in the parent patent and in not holding that since these claims were believed and intended to be, and apparently are, of a breadth to cover the subject-matter of the divisional patent, the delay in presenting the claims in the divisional patent is excused.

3. The Circuit Court of Appeals erred in reversing and in not affirming the decree of the District Court sustaining the parent and divisional patents as valid and infringed, and in awarding costs to defendant-respondent.

ARGUMENT.

I.

The Circuit Court of Appeals for the Second Circuit has extended the doctrine of Webster v. Splitdorf beyond anything justified by that or any other decision of this Court.

In *Chapman* v. *Wintroath*, 252 U. S. 126, this Court reiterated the rule that a divisional application is entitled to the benefit of the filing date of the parent application "with all its priority of right" and for anything disclosed in the parent application, whether claimed in the parent application or not. In the same case this Court also stated, as an exception to that rule, that where a patent has issued to another more than two years before its claims are copied by a divisional applicant for interference purposes, the lapse of such a period bars the divisional applicant from copying and obtaining the claims in the issued patent.

In *Webster Co.* v. *Splitdorf Co.*, 264 U. S. 463, this Court announced a further exception to the rule that a divisional application relates back to the filing date of the parent application.

The facts of the *Webster* case briefly were: The original application for the Kane patent in suit was filed Feb-

ruary 2, 1910. In 1915 Kane filed a divisional application, in the prosecution of which on June 17, 1918, claims were presented to subject-matter *deliberately* not claimed either broadly or specifically in the original application, because Kane considered their subject-matter one merely of design. *These claims were presented five years after a complete disclosure of their subject-matter appeared in an issued Podlesaks patent and an equal length of time after the device had been in general public use.* This Court found "that Kane did not originally intend to assert" the claims, that the claims were "broader than those originally sought" and "that the delay was unreasonable, and, under the circumstances, as shown by the record, constitutes laches" by which Kane lost his right to a patent on the subject-matter of the late presented claims.

We do not understand that this Court held in *Webster* v. *Splitdorf,* as stated by the Court of Appeals for the Second Circuit, that in *any* case where there has been a delay of more than two years in presenting claims in a divisional application, such delay, *even in the absence of public use or intervening rights,* invalidates the delay in the absence of excuse. The facts in the case at bar are not analogous to those in the *Webster* case. While here there was a lapse* of more than two years in presenting the claims of the divisional patent, *yet here had been no adverse public use of the invention before or during the two year period. Nor had there been any disclosure of the invention in an issued patent or printed publication,* except the Johnson patent No.

*In the case at bar, the Court of Appeals, reversing the District Court, held that there was a lapse *after previous claiming of the divisional patent invention* and not delay with no previous claiming, as in the *Webster* case. The Court of Appeals found that Warth had claimed the divisional patent subject-matter in his parent application, but that there was a lapse in the assertion of claims thereto between December, 1930 and April, 1933 (R., p. 2153). Hence, this case is distinguished from the *Webster* case where the invention had not been claimed in the parent application and the failure was deliberate.

1,852,578 (R., p. 746), which issued *only a year* before the claims were asserted, and, therefore, well within the two year period allowed for copying the Johnson claims under the *Chapman* case, *supra.* Moreover, as the Court of Appeals found, Warth had claimed broadly the subject-matter of the divisional patent during the pendency of his parent patent, and hence there was no *deliberate* failure to claim the subject-matter prior to claiming it in the divisional application. On the contrary, the Court of Appeals held that Warth did prosecute in the parent application claims covering the subject-matter of the divisional patent (R., p. 2151). Further, Warth *believed* he had covered the invention of the divisional patent by the claims issued in the parent patent. The claims of the parent patent *apparently are* of such breadth; the District Court so held (R., p. 2082) although the Court of Appeals later construed narrowly the parent patent claims.

In short the Court of Appeals held that Warth's unintentional *lapse* in claiming the specific divisional patent method for two years and four months, *absent intervening rights,* is the equivalent of the eight year *deliberate delay and failure* to claim an invention, considered in the *Webster* case, *where public rights in the meantime accrued.* On this finding, the Court has denied Warth the benefit of the general rule that the divisional patent relates back to the filing date of the parent patent.

The uncertainty with respect to the exception to this general rule announced in the *Webster* case, is recognized by the Circuit Court of Appeals for the Sixth Circuit in *Wagenhorst* v. *Hydraulic Steel Co.,* 27 Fed. (2d) 27, 29, (Denison, J.,) where the Court said, referring to the *Webster* case:

> "It is not clear from the opinion what result would have been reached, if based upon only a part of the circumstances."

The Court (C. C. A. 6th) then proceeded to point out that the controlling fact in the *Webster* decision was not the fact that the claims were presented after delay *"but because it extended so long after the 1913 public disclosure"*. This, we believe to be the correct interpretation of this Court's decision in the *Webster* case.

The extreme harshness of the rule announced by the Circuit Court of Appeals for the Second Circuit is evident from the fact that it applies to divisional applications a two year time limit which is not imposed upon them by the fundamental statute.* The statute bars the allowance of a patent *only if there has been a printed publication, public use or sale of the invention more than two years before the filing date of the application.* The rule established by the Court of Appeals for the Second Circuit requires an excuse for delay and *prima facie* bars a patent whether statutory bars, as such or by analogy, exist or not. The rule, as applied in this case, therefore, contrasts with the statement of this Court in *United States* v. *American Bell Telephone Co.*, 167 U. S. 224, 247, that "No court can disregard any statutory provisions in respect to these matters on the ground that, in its judgment, they are unwise".

. . .

In the present case, aside from the admitted use of the invention by plaintiff,** neither the District Court, nor the Court of Appeals, found evidence of any use of the invention or public disclosure thereof more than two years before the filing of the divisional application. Consequently, under the rule of the Circuit Court of Appeals for the Second Circuit a divisional application is not entitled even to the benefit of its own filing date if there has been a two-year lapse in claiming its subject-matter.

---

*U. S. C., title 35, sec. 31, p. 3 of Petition.

**Held by the Circuit Court of Appeals for the Sixth Circuit in *Wirebounds Patents Co. et al.* v. *Saranac*, *infra*, p. 23, not to bar a divisional application since not an *adverse* use.

The Court of Appeals found no statutory bars and refers only to the issuance of the parent Warth patent and to the issuance of the Johnson patent during the two year period. But the parent Warth patent *contained no description of the invention,* and hence was not a printed publication. The Johnson patent issued *less than one year* before the claims were presented, and hence is not a bar under the decision of this court in *Chapman* v. *Wintroath, supra.* Consequently, the Court of Appeals for the Second Circuit overlooks the admonition of this Court in the *Chapman* case with reference to a patent such as Johnson's that:

> "Such a prior patent is in no sense a bar to the granting of a second patent for the same invention to an earlier inventor, provided that his application is filed not more than two years after the date of the conflicting patent. The applicant may not be able to prove that he was the first inventor but the statute gives him two years in which to claim that he was and in which to secure the institution of an interference proceeding in which the issue of priority between himself and the patentee may be determined in a prescribed manner."

Warth acted in compliance with the above rule, copied the Johnson claims within one year from the date his patent issued, and was awarded the claims as prior inventor.

II.

There is an irreconcilable conflict between the Circuit Courts of Appeals for the Second, First, Sixth and Eighth circuits as to the applicability of Webster v. Splitdorf to a case where claims have been inserted in a divisional application more than two years after the filing of the parent application but less than two years after there was an intervening public use, patent or publication.

The Circuit Court of Appeals for the Second Circuit has evidently seized upon this Court's reference in the *Webster* case to the two year limit against broadened reissue pat-

ents* as a basis for its holding that when there has been a lapse of two years in presenting claims to particular subject-matter in a divisional application, such delay invalidates the claims in the absence of valid excuse, *notwithstanding the fact that there may have been no adverse public use of the invention or disclosure of it in a printed publication or patent more than two years prior to the date the claims are presented, as there was in the Webster case.*

The interpretation of the *Webster* case by the Circuit Court of Appeals for the Second Circuit directly conflicts with the interpretation adopted by the Court of Appeals for the First and Sixth Circuits whose decisions are discussed in the foregoing petition at pp. 5, 6. The following extracts from the opinion by these latter Circuits demonstrate that each of them construed the doctrine of *Webster* v. *Splitdorf,* as applicable **only** where the claims of the divisional application were first presented more than two years *after the invention was disclosed to the public by adverse use, publication or patent.*

Utah Radio Corp. Products Co. v. *Boudette,* (C. C. A. 1st), 78 Fed. (2d) 793.

The Court, stating the facts of the *Webster* case, pointed out that the subject-matter of the divisional claims had been disclosed in a Podlesaks patent issued over five years before the claims were first presented and had been in public use by others than the patentee for over five years. The court said (at 799) after *referring to the Webster case,* that claims may "reasonably" be presented at any time within two years after the adverse public use:

*There is no analogy in the case at bar to an application for reissue filed more than two years after the original patent issued, since there was no printed disclosure in the parent Warth patent, as in the case of an original patent to be reissued. Hence, this analogy mentioned in the *Webster* case does not apply.

"In that (*Webster*) case the court applied by way of analogy *the statutory two year period of prior publication and public use* * * *.

"There the subject-matter of claims 7 and 8, though not claimed in the Podlesaks patent, *was disclosed by it,* and consequently, on the issuance of that patent in 1913, *was published and given to the public.*"

"In the case now before us, the subject-matter of claims 1, 2, and 5 here in issue was known and in public use through the sale of RCA loudspeaker 104 in November, 1925, some four years before claims 1, 2 and 5 were asked for, whereas *they reasonably could have been inserted in the original application* of April, 1926, *or at any time thereafter up to two years from November, 1925,* but were not until October 17, 1929, when the divisional application was made."

* * * * *

Wagenhorst v. *Hydraulic Steel* (C. C. A. 6th) 27 F. (2d) 27, 29.

The Court (Denison, J.,) after reciting the facts of the *Webster* case said:

"From the recitals and reasoning of the opinion, we are unable to see that the fact that the amendment of 1918 was presented in a divisional application, instead of an original application, was of any importance to the result reached. The long delay which elapsed between the original and the divisional was important, *not because it was the interval between these two applications, but because it extended so long after the 1913 public disclosure.* If the original application of 1910 had not matured into a patent in 1916, but had continued pending, and the amendment in 1918 had been offered in that original application, and the facts had been otherwise the same, we see nothing in the opinion, and no reason occurs to us which would indicate a different result. In other words, claims 7 and 8 were invalid because, in an effort to *broaden any previous statements of the invention, they were first presented* by an amendment offered *five years after their subject-*

matter had been disclosed to the public by the Podlesaks patent; and such an effort to broaden the claim of the invention was, by analogy to the reissue rule, barred by laches, estoppel, and intervening rights. In the present case the divisional application was filed promptly after the intervening device appeared, and the Webster case does not apply."

* * * * *

Wirebounds Patents Co. et al. v. *Saranac,* (C. C. A. 6th), 37 F. (2d) 830, 840, 841.

The District Court had held the patent in suit invalid under the ruling in the *Webster* case. The Court of Appeals (Denison, J.,) discussing the *Webster* case said:

"This was before we had by our Wagenhorst case, * * * adopted our interpretation the Splitdorf decision." * * *

"This case is plainly not within the Splitdorf rule, as we understand it, either by parallelism or by strict analogy. Defendant points out, as a general analogy, that the machine and method had been in public use by the applicants, who became the patentees, and under licenses from them, all for more than two years before the divisional application was filed. This is true. When it is remembered that the divisional application is normally entitled to the benefit of the original filing date, it is not easy to see how public use under license from the applicants can amount to that laches under which adverse rights may arise; *or how the Splitdorf rule can apply unless the delay is after the public appearance of an adverse claimant, or perhaps, one who may be an adverse claimant;* but we find it unnecessary to decide that question."

The decision by the Circuit Court of Appeals in the case at bar also conflicts with the interpretation of the *Webster* case adopted by the United States District Court for the District of Delaware (Morris, J.,) in *Dubilier Condensor*

Corporation v. *Radio Corporation of America*, 34 F. (2d) 450, 462.*

The Courts of the First, Third and Sixth Circuits have, therefore, restricted the application of the ruling in the *Webster* case to a situation in which the invention has been generally made available to the public more than two years prior to the presentation of the claims either by disclosure in another patent or by adverse public use or sale. Such facts create bars recognized by the statute (U. S. C. title 35, sec. 31, p. 3 *ante*) against the issuance of patents on an original application and therefore afford a basis for a finding of invalidity on grounds analogous to those created by the statute. But there is no such basis here.

The Circuit Court of Appeals for the Eighth Circuit has held in *Hartford-Empire Co.* v. *O'Bear-Nester Glass Co.*, 39 F. (2d) 769, upon the authority of this Court's decision in the *Webster* case, that although claims may be presented in a divisional application after the lapse of more than two years, yet where in the meantime a patent "shall have been issued to a *stranger* more than two years after the original applicant files his original application" the claims are barred. In that case, the court after referring to *Webster* v. *Splitdorf*, *Chapman* v. *Wintroath* and the *Wagenhorst* case, *supra*, said (at 776):

> (3) "(d) Absent estoppel in pais, through accrual of public or private rights, such amendments of claims, or the filing of such divisional applications, may be allowed more than two years after the original application is filed, or after the last preceding divisional ap-

---

*In the *Dubilier* case the Court, after referring to the fact that the claim (9) was not submitted until three and one-half years had elapsed after the divisional application was filed, said, in distinguishing the facts from the *Webster* case and others:

> "But unlike those cases, in the suit at bar there was no delay of more than two years *after others had entered the field* and there is no presumption that Dunmore had knowledge of defendant's loud speaker, or that the amendment was motivated by it."

plication is made. (e) *But if a patent*, which makes claim to the subject-matter present and disclosed in the application of the original applicant, but not claimed by the latter, *shall have been issued to a stranger more than two years after the original applicant files his original application, the latter can thereafter neither amend his original claims* (so as to broaden them) *nor file a divisional application*, embracings claims, so after two years patented to a stranger."

The above quoted ruling squarely conflicts with the decision by this Court in *Chapman* v. *Wintroath*, *supra*, but apparently would have justified the conclusion reached in the case at bar, since the Warth divisional application was not filed until more than two years after the original Warth application and the Johnson patent No. 1,852,578 was granted before the divisional patent claims were asserted.

The ruling of the Circuit Court of Appeals for the Eighth Circuit in the *Hartford* case, *supra*, also squarely conflicts with the ruling of the Sixth Circuit Court of Appeals in the *Wagenhorst* case, *supra*, where the Court said:

> "The opinion (*Chapman* v. *Wintroath*) has been sometimes thought to indicate that the deadly two-year period begins to run from the time of filing the original application * * *",

and then proceeded to state its own contrary interpretation of this Court's decision in the *Chapman* case.

This further conflict between the Second and Eighth Circuits on the one hand, and the First, Third, and Sixth Circuits on the other, shows the great uncertainty which has arisen with respect to the meaning of this Court's decision in *Webster* v. *Splitdorf*.

III.

There is a further irreconcilable conflict between the Circuit Courts of Appeals for the Second and Sixth Circuits as to what constitutes valid excuse for delay in presentation of claims in a divisional application.

This Court said in the *Webster* case that delay of more than two years may be excused "by special circumstances which show it to have been not unreasonable". The finding by the Circuit Court of Appeals for the Second Circuit in the case at bar that there is no excuse for the delayed presentation of the claims in the Warth divisional patent ignores the *apparent* and *intended* breadth of the claims in the parent patent. The Court of Appeals stated (R., p. 2153) that, had it interpreted the claims of the parent patent to dominate the method of the divisional patent, the delay in presenting the specific divisional patent claims would be excused. But the Court refused to accept as an excuse for the delay the "special circumstance" that the parent patent claims were *intended* and *believed* to dominate the divisional patent method, *and were reasonably susceptible to such an interpretation,* as shown by the fact that the District Court so interpreted them.

The Court of Appeals tacitly admitted that the parent patent claim *might* be interpreted in accordance with the District Court finding, but said that such interpretation "would make it invalid under the old 'slide machine' "* (R., p. 2152). Consequently, the Court declined to follow the District Court, and instead read into the claims the "heated plunger" limitation.** Such a construction of patent claims was condemned by this Court in *Altoona* v. *American Tri-Ergon,* 294 U. S. 477. Manifestly, Warth should not be held

*This was the machine used by plaintiff before the methods of the patents in suit were developed.

**We have included in an appendix an explanation of the Warth patents sufficient to enable the Court to understand the strained construction of the claims to which the Court of Appeals resorted.

accountable for failure to anticipate the action of the Court of Appeals in inserting a limitation into his claims which the language thereof does not require. Certainly, Warth's confidence in the breadth of the parent patent claims was not "unreasonable", in view of the fact that the District Court later found that the claims *do* dominate the subject-matter of the divisional patent. Under these circumstances, we submit that Warth's action in relying upon the parent patent claims was reasonable and satisfies the requirement laid down by this Court in the *Webster* case that delay may be overcome by "circumstances which show it to have been not unreasonable".

The limited construction of the parent patent claims adopted by the Court of Appeals is particularly strained in the case at bar, since the heated plunger (read into the claims) was not originally disclosed by Warth in his parent application as filed, and was illustrated and described by an amendment presented in response to *a Patent Office requirement* (R., p. 1497) for a drawing. When the drawing was presented, the illustrated heated punch was identified only as "suitable mechanism" for practicing the method broadly described (R., p. ~~1490, ll. 3-37~~ 1514, l. 31).

The refusal by the Court of Appeals to accept the *intended* and *apparent* breadth of the parent patent claims, upon which Warth reasonably relied to dominate the divisional patent preheating method, as an excuse for the delay, conflicts with the ruling by the Court of Appeals for the Sixth Circuit in *Wagenhorst* v. *Hydraulic Steel Co.*, 27 F. (2d) 27, 31, in which the Court held that a claim in the parent application or patent which *seems* of broad scope, *regardless of the finally determined actual scope*, is a reasonable excuse for the delay. The Court said in the Wagenhorst case:

> "It may be said, with some certainty as to original claim 2, and with some probability as to claims 1 and 3, that, if granted, they would *have seemed to cover defendant's later structure, and might or might not have been construed in that way.* The trouble was that with

that construction they went beyond the applicant's device and reached the prior art. Wagenhorst's amended divisional claim restricted his claimed invention to the specific form of its concrete embodiment. This is a very different thing from the enlargement in the Webster case."

An apparently broad claim in an earlier application or patent, and an inventor's reliance thereon, even though mistaken, has been held by other Courts to be an excuse for delay in asserting claims, and to negative abandonment. See *McGrath* v. *Burke,* 12 F. (2d) 161, 162 (Appeals, D. C.) and *MacLaren* v. *Stoetzel* (C. C. P. A.) 38 F. (2d) 125, 129.

Since, as the Court of Appeals stated, Warth's delay would not have been "unreasonable" had his parent patent claims been construed to cover the subject-matter of the Warth divisional patent claims, the secondary question is simply this—

Should the criterion of the diligence of an applicant in presenting specific claims in a divisional application be (*a*) the scope of the parent patent claims finally determined by judicial construction, as held by the Second Circuit, or (*b*) as held by the Sixth Circuit, the *seeming* or *apparent* scope of the parent patent claims reasonably* *relied upon* and *intended* by the patentee?

We submit that the latter is the correct rule since one's diligence at a particular time should be measured in the light of the circumstances (parent patent claim scope) as then reasonably understood by him and not as later and unexpectedly determined upon judicial inquiry.

IV.

The questions involved are of vital public importance.

Under the statutes, the patent is issued to the first discoverer. But an invention is not completed until it has been reduced to practice, either actually or constructively by the

*As indicated by the District Court's opinion in the case at bar.

filing of an application. This Court stated in *Chapman* v. *Wintroath, supra,* "not only have later or divisional applications not been dealt with in a hostile spirit by the Courts, but, on the contrary, designed as they are to secure the patent to the first discoverer they have been favored."

. . .

The substantial number* of divisional applications and patents are the result of requirements by the Patent Office that applications disclosing several inventions must be divided so that only a single invention is covered in a single patent. These requirements have not diminished the completeness of application disclosures, because of the liberal policy with which the Patent Office and the Courts have generally favored divisional applications.

But it must be recognized that many divisional applications are not, and cannot be filed within two years from the filing of the original application. In many cases, it is only in the course of prosecution after a lapse of two years, that an inventor is caused to realize, as here, the necessity for *specific* claims to particular phases of his disclosure. This delayed recognition of the need for specific claims frequently results in later filed divisional applications. *Such exigencies are not recognized by the decision of the Court of Appeals for the Second Circuit,* which in the case at bar has applied the harsh rule that a two year delay in presenting claims by divisional applications creates a presumption against the patent validity. It is vital, therefore, in view of the varied conditions under which the necessity for divisional applications arises, and for a continuance of the policy of favoring these applications, that this Court definitely state the *limitations* of the *Webster* case exception to the rule that divisional applications shall have the priority rights of parent cases. Unless and until this is done, the public and inventors alike will have no certainty as to when, and under what conditions, divisional applications may be filed or valid divisional patents granted.

---

*See typical figures in Petition, footnote p. 10, *ante.*

Conclusion.

In conclusion, we respectfully submit that not only should the conflict between the several circuits with respect to *Webster* v. *Splitdorf* be resolved by an authoritative statement by this Court, but also that this Court should hold—

(a). That claims in a divisional application shall be deprived of the benefit of the filing date of the parent application only when there has been a delay in presenting them for more than two years after an intervening right in the form of an adverse public use or disclosure, such as a printed publication or patent.

(b). That a mere lapse of two years in presenting claims in a divisional application does not prima facie bar their allowance or require excuse.

(c). That when an inventor has obtained in a parent patent claims which are intended and believed to, and apparently do, cover the subject-matter of the claims of the divisional patent, his delay in presenting specific claims in the divisional patent is excused.

Respectfully submitted,

THOMAS G. HAIGHT,
GEORGE F. SCULL,
JOHN J. DARBY,
GEORGE W. PORTER,
Counsel for Petitioners.

Appendix.

The method of the parent Warth patent Reissue 19,117 (R., p. 711), is illustrated by the attached drawing. A line of assembled crowns* is fed step by step beneath a heated punch. A strip of facing material coated with a thermoplastic (heat-softened) adhesive, such as metal foil coated with gutta percha, is fed over a line of assembled crowns, a spot is punched from the strip and the punch carries the spot down and adheres it under heat and pressure (from the punch) to the cork disc of the assembled crown. The cutting punch is then raised and the crown moved to the next position where the spot is again subjected to pressure from a heated plunger, thus insuring a more perfect union. Finally, the now-spotted crown is held under a cold plunger until the adhesive is cool. This operation is performed at the rate of five hundred "spots" per minute for each punch (R., p. 96).

The Warth divisional patent No. 1,967,195, dated July 17, 1934 (R., p. 716) covers a method also illustrated by an attached drawing. The divisional patent differs from the parent patent, in that it describes the heat as being applied to the spot by preheating the cork disc which applies its heat to the spot and the claims are limited to this specific way of applying the heat to the spot. In other words, the cork disc is preheated so that at the instant the center spot is deposited, heat is applied to the spot from the cork disc.

The relationship of the two patents can be best explained by referring briefly to the history of the parent patent. The application for the parent patent filed in January, 1927 disclosed generally the step of applying heat and pressure to the spot at the instant it is deposited on the cork. It also specifically explained that the heat might be applied to the spot by preheating the cork disc. The method was claimed broadly while the application was pending, but no claims

*"Assembled crown" designates a metal shell of the crown type having a cork disc inserted therein.

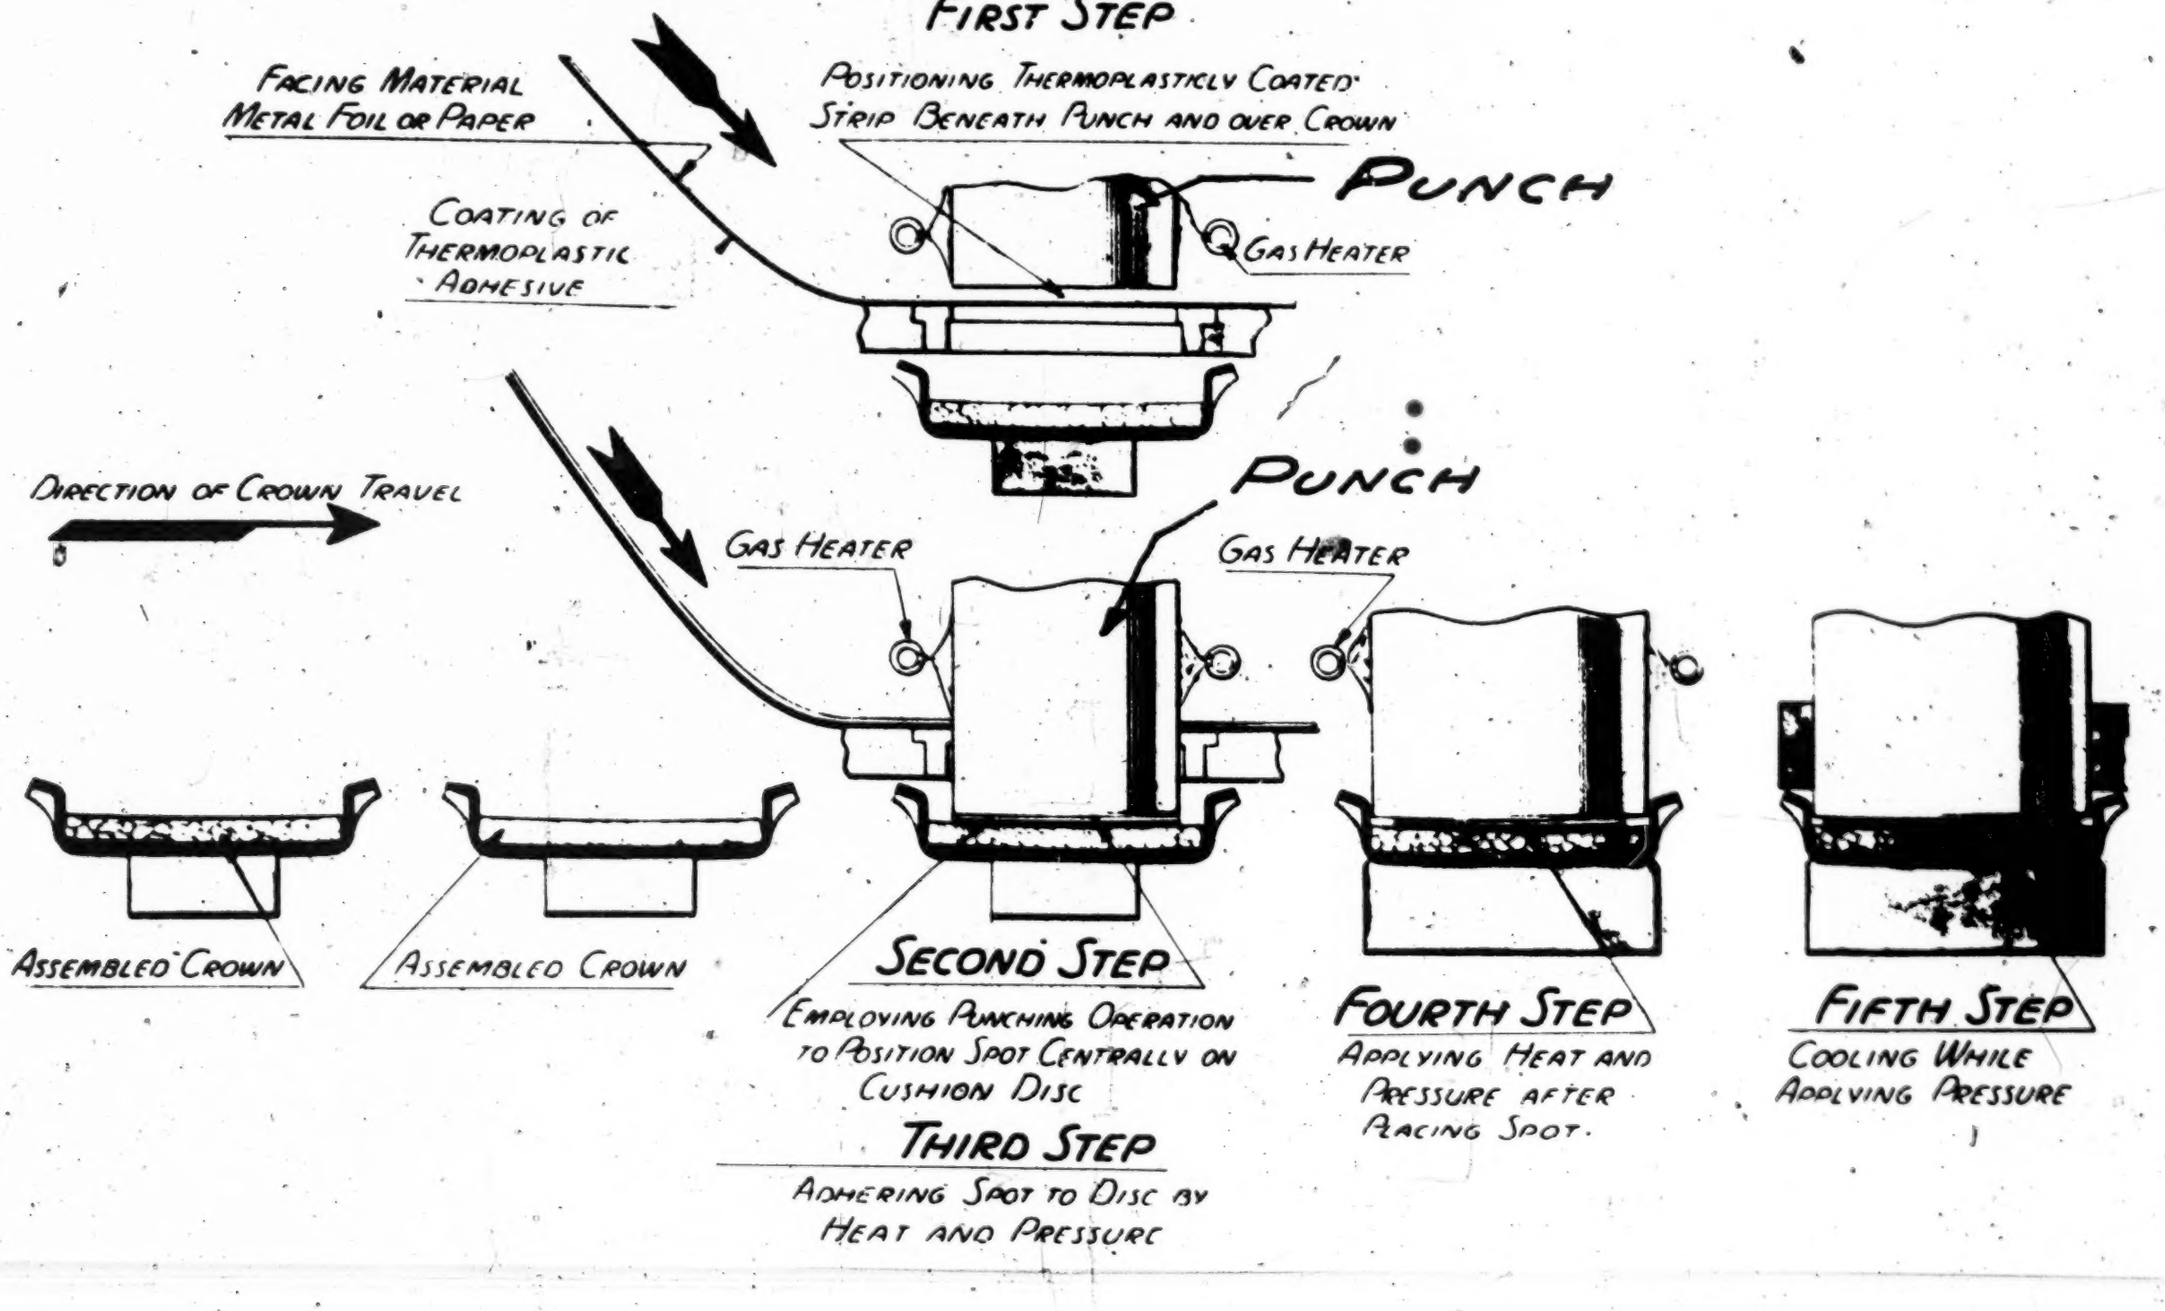
specific to preheating the cork were presented. Shortly before the issuance of the parent patent, the reference to preheating the cork was cancelled, and there was substituted the **broader** expression that the invention is *"to utilize at the time of assembly both heat and pressure to unite the spot to the cork"* (R. p. 714 l. 47). At the same time the claims were amended to include the expression "upon assembly applying simultaneously to the spot pressure and sufficient heat to render the adhesive tacky." The patent issued with this language in the specification and claims. Claim 3* is typical of the two parent patent claims in suit.

The District Court held (R., p. 2082) that the language of the parent patent specification and claims covered broadly the application of heat and pressure to the spot instantly upon assembly of the spot with the cushion disc, *regardless of the source of heat, i. e.,* whether by the punch, as described in the parent patent, or by a preheated cork, as described and claimed in the divisional patent. The Court of Appeals held that the expression *"applying simultaneously to the spot pressure and sufficient heat"* limits the claims to the application of heat to the spot by a heated plunger. As thus interpreted, the Court read the

---

*3. The improved method of manufacturing caps of the type having an interior disc of cushion material provided on its exposed face with a center spot, which comprises providing spot material in strip form having one surface formed of an exposed continuous coating of water resistant adhesive which is normally hard at room temperature but becomes tacky upon the application of heat and having another surface to be exposed to the contents of a capped container, cutting from said strip a facing spot having one surface completely coated with said adhesive with a cap disposed beneath the portion of the strip from which the spot is cut, whereby the cutting operation positions the spot upon the cushion material with the coating between the spot and the cushion material, *and upon assembly applying simultaneously to the spot pressure and sufficient heat to render the adhesive tacky,* thereby causing the spot to adhere to the cushion material and thereafter permitting the adhesive to cool and harden while subjecting the assembled unit to pressure. (Italics ours.)

"heated plunger" into the claims so that the clause reads, (containing in italics the limitation inserted by the Court):



> "upon assembly applying simultaneously to the spot *by a heated plunger* pressure and sufficient heat to render the adhesive tacky".

Under this interpretation, the Court of Appeals reversed the District Court and held that the defendant did not infringe the parent patent because the defendant applied the heat mainly by preheating the cork, although partly by a heated plunger.

OCTOBER TERM, 1936.

No. 1008.

CROWN CORK & SEAL COMPANY, INC., *Petitioner*,

v.

FERDINAND GUTMANN CO., INC., *Respondent*.

REPLY BRIEF FOR PETITIONER.

We would not reply to respondent's brief except for the fact that it attempts to answer the petition by statements which are directly contrary to the record and the undisturbed fact findings of the District Court.

Respondent seeks to mislead this court to conclude that the questions submitted by the petition involve issues of fact. But that is not the case, since *every alleged issue of fact raised by respondent as to the questions of the petition has been expressly decided against respondent by the District Court, whose findings were not disturbed by the Court of Appeals.*

I.

The Decision of the Court of Appeals Holding Invalid the Warth Divisional Patent 1,967,195 Does Change the Established Practice With Respect to Divisional Applications (Resp. Br. p. 12).

Respondent's contention that the Court of Appeals' decision does not change the established treatment of divisional applications is extremely misleading. We repeat the statement (Pet. p. 5) that it does. A complete answer to respondent's contrary contention is to be found in the testimony of the Commissioner of Patents before the Senate Committee on Patents on June 24, 1937.* The Commissioner stated with reference to the case at bar:

> "Recently there has been presented to the Supreme Court a petition for a writ of certiorari to review the decision of the Circuit Court of Appeals of the Second Circuit in the case of *Crown Cork and Seal Company, Incorporated,* v. *Ferdinand Gutmann* (86 F. (2d) 698), predicated upon a conflict of decisions in the different circuits as to the proper interpretation to be given to the decision of the Supreme Court of the United States in *Webster Electric Company* v. *Splitdorf Electric Company* (264 U. S. 463). In that later decision the Supreme Court had discussed the effect of delay under certain circumstances in filing a divisional application and as to the validity in view of such delay of a patent granted on such divisional applications.
>
> If the Supreme Court should grant the writ and affirm the decision of the Circuit Court of Appeals of the Second Circuit, it may well be that a number of patents granted by this office would be invalid. *If the writ is refused, the rights of an inventor in a divisional application will, for an indefinite period, remain uncertain, and the Patent Office will not know how to proceed in such applications.*"**

*With respect to Senate Bill S. 475, providing for a single Court of Patent Appeals. A printed copy of the testimony has been filed with the Clerk; the above quoted statement appears at p. 119.

**Emphasis ours throughout.

Moreover, respondent's contention is based on the assumption that the Patent Office violated its own rules and practice in allowing the Warth divisional patent. Obviously it did not, since the divisional patent was issued after an interference in which the divisional patent application was deliberately given the benefit of the 1927 filing date of the parent patent (R., p. 864) as well as the benefit of the filing date of the 1930 divisional application. From that 1930 application the later 1933 application resulting in the divisional patent was carved. Warth might have amended the 1930 application instead of filing the 1933 division, but that he did not is immaterial, since the division was no more than an amendment of the 1930 application.

> "It is now settled law * * * that a divisional application is no more than an amendment of the parent application." *Dwight and Lloyd* v. *Greenawalt*, 27 Fed. (2d) 823, 831 (C. C. A. 2nd).

Respondent contends that Warth's 1933 application should not have been accorded by the Patent Office the filing date of his 1930 application, containing a disclosure of the invention of the divisional patent, because the 1930 application contained no *claims* to the divisional patent method. But this contention completely overlooks the fact that the 1930 Warth application, filed before the parent patent issued, was in every respect the legal equivalent of the parent application considered by this Court in *Chapman* v. *Wintroath*, 252 U. S. 126. In the Chapman case the parent application disclosed the invention in controversy, *but did not claim it.* A division was filed six years after the filing of the parent case claiming the invention and the division was accorded the filing date of the parent case. That is exactly what the Patent Office has done for over fifty years and did in the case at bar. The Patent Office simply accorded Warth's 1933 application the benefit of the filing date of the co-pending 1930 application which disclosed, but did not claim, the invention in issue and also the benefit of

the parent patent filing date (1927); since with the latter the 1930 case was co-pending.

The case of *Fessenden* v. *Wilson*, 48 Fed. (2d) 422 cited by respondent (Br., p. 18) obviously is not in point. Fessenden filed no application disclosing the subject-matter before his alleged parent patent issued. Hence, the Court held that when the patent issued, there was "nothing left pending before the Patent Office upon which it could act or to which the latter application could attach." In other words, there was no continuity of disclosure pending before the Patent Office. Here, Warth did file his 1930 application, to which the 1933 application attached, before his parent patent issued.

II.

The District Court Found that There Were No Adverse Intervening Rights and the Finding Was Not Disturbed by the Court of Appeals Although Respondent Urged that it Was Error.

Respondent agrees with the interpretation of *Webster* v. *Splitdorf* by the Circuit Court of Appeals for the First and Sixth Circuits, since it states (Br., p. 20) that unless the Circuit Court of Appeals for the Second Circuit found as a fact that there were intervening rights, "it would not have reversed the District Court and applied the doctrine of *Webster* v. *Splitdorf*." Respondent then argues that, although the Court of Appeals referred to no intervening rights, the record shows facts which establish such intervening rights by respondent and others.

The Court should not be misled by this attempt to raise issues of fact already decided in favor of petitioner. *Every argument advanced by respondent in support of its contention that the record shows intervening rights was expressly considered and rejected in the opinion of the District Court, whose findings were not disturbed by the Court of Appeals.* Yet, as pointed out in the petition (footnote p. 3), respon-

dent urged before the Court of Appeals that these findings were error.

Respondent contends (Br. p. 20) that machines purchased by it in September, 1928, December, 1928, March, 1929, and April, 1929, had the preheating* method of the divisional patent; these machines are covered by respondent's Exhibit Q (R., pp. 1102-1103). In rejecting this contention the District Court said (R., 2100):

> **"* * * the defendant has not proved any use of the preheating method, to anticipate the filing date of the first divisional application, November 7, 1930, or the filing date of the second divisional application, April 4, 1933."**

This finding of the District Court was not disturbed by the Court of Appeals, which based its holding of invalidity *solely* upon (1) the issuance of the Johnson patent less than a year before the divisional application was filed and (2) the issuance of the Warth parent patent which contained no description of the preheating method. This was done notwithstanding respondent's argument that the finding quoted above was in error.

This court has repeatedly held that questions decided by a master or a trial court on conflicting evidence and involving the credibility of witnesses will not be reviewed if there is a basis, as here, for such findings. Respondent is attempting to anticipate by prior use the filing date of the Warth divisional patent, although the District Court has held that it did not establish prior use or adverse intervening rights. Consequently, respondent's contention is completely answered by the ruling of this Court in *Adamson* v. *Gilliland*, 242 U. S. 350, 353:

> "Considering that a patent has been granted to the plaintiff the case is preeminently one for the applica-

*"Preheating" is used in the decisions below and by both parties to distinguish the divisional (1,967,195) patent from the parent patent (Reissue 19,117).

> tion of the practical rule that so far as the finding of the master or judge who saw the witnesses 'depends upon conflicting testimony, or upon the credibility of witnesses, or so far as there is any testimony consistent with the finding, it must be treated as unassailable' (citing) *Davis* v. *Schwartz,* 155 U. S. 631, 636.''*

Obviously the Court of Appeals would have reversed the finding of the District Court that there were no intervening rights had it regarded that finding in error, as contended by respondent. That the Court of Appeals deliberately refrained from disturbing the finding of the District Court is clear not only from the fact that the issue of intervening rights was argued and briefed on appeal, but also from the fact that the precise questions raised by the petition were presented by petition for rehearing which was denied.

III.

The District Court's Finding of No Intervening Rights is Clearly Supported by the Record.

Respondent admits (Br., p. 20) that two machines which it purchased in July and August, 1928, did *not* have the ''preheating'' invention of the divisional patent. The District Court so found (R. 2099, 2100). Respondent's Vice President testified that the spotting mechanism in the machines (Exhibit Q) purchased later in 1928 and in 1929 ''*was the same as on the previous machine*'' (R., 289, Q. 93). Yet the ''previous machine'' is the August, 1928, machine which respondent admits and the District Court found did not have the preheating invention of the divisional patent. Respondent's witness Johnson so testified (R., 238, 239). Consequently, according to defendant's own testimony,

---

*The cases are uniform to the effect that this court accepts a finding by a trial court or a master made from contrary evidence involving the credibility of witnesses where the finding has not been disturbed by the Appellate Court. See: *United States* v. *United Shoe Machinery Co.*, 247 U. S. 32, 37, 41; *Mason* v. *United States*, 260 U. S. 545, 556; *Cramer* v. *United States*, 261 U. S. 219, 226.

these September and December, 1928 and the 1929 machines did not have the divisional patent invention since they are conceded to have been like the earlier 1928 machines which did not.

It is preposterous, therefore, in the face of these direct admissions by respondent's own witnesses, for respondent now to assert that the record shows what the District Court held it does not show, and what the Court of Appeals refused to find in the face of respondent's contentions that the finding of the District Court should be reversed. Obviously, such an unfounded assertion is no adequate answer to the petition.

Respondent also refers (Br., pp. 23, 24) to certain machines which petitioner had Johnson build on special order for petitioner's Canadian plant. It is difficult to see how manufacture for petitioner and use by the latter can create an adverse intervening right against petitioner's divisional patent. The District Court held that it did not, saying (R., 2099):

> "The fact that Johnson, in 1929, built some machines for the plaintiff on special order for plaintiff's own use, does not affect the validity of the Warth patents, and does not anticipate a divisional application. (Citing) *American Chain Co.* v. *Franklin New York Co.*, 34 Fed. (2d) 551-555."

This finding was not disturbed by the Court of Appeals and was in accord with the ruling of the Circuit Court of Appeals for the Sixth Circuit in *Wirebounds Patent Co. et al.* v. *Saranac*,* 37 Fed. (2d) 830 (Petition p. 23), that

*The ruling of the Court of Appeals for the Sixth Circuit on the method patent discussed in this decision was not reversed by the Supreme Court as suggested by respondent (Br. p. 29). On the contrary the patent again came before the Court of Appeals which stated that the Supreme Court had not passed thereon and (65 F. (2d) 905) that *Webster* v. *Splitdorf* applies only when there is delay of more than two years after issuance of a patent to another and when the claims presented are broader than those originally sought in the parent application.

use by a patentee does not invalidate a divisional patent, since it is not an adverse use.

Finally respondent refers (Br., p. 22) to certain papers in the Patent Office records as indicating sale by Johnson of some sixteen apparatus and respondent asserts that these apparatus embodied the divisional patent invention. This assertion also is contradicted by the undisturbed finding of the District Court which said (R., p. 2100):

> "There is no evidence to show that the Johnson machines sold to others than plaintiff and identified on the list had a preheater * * *."

IV.

Respondent's Assertion that Petitioner Had Knowledge of Intervening Rights is Contradicted by the Record and the Undisturbed Finding of the District Court.

The unsupported assertion (Resp. Br., p. 22) that petitioner had knowledge of prior use of the divisional patent invention is contradicted not only by the undisputed testimony of petitioner's Vice-President (R., pp. 683; 685; 689) that petitioner had no such knowledge prior to filing the divisional patent application, but also by the finding of the District Court (R., p. 2101):

> "As soon as it came to Warth's attention that any one else was claiming the invention he, *being unaware of what methods others were using, and having no knowledge of defendant's using the preheating method*, proceeded as the statutes permitted, and in accordance with the practice recognized by the Patent Office and the courts. *Overland Co.* v. *Packard Co.*, 274 U. S. 417.
>
> In making the claims to the preheating step Warth was covering what he had invented, without any intent to expand his disclosures to cover later methods which had come to his attention. This has been approved by the courts. *Carson* v. *American Smelting and Refining Co.*, 4 Fed. (2d) 463, 470; *Remington Cash Register Co.* v. *National Cash Register Co.*, 6 Fed. (2d) 614; *Overland Co.* v. *Packard Co., supra.*"

Clearly, therefore, there is no showing of intervening rights or any issue of fact with respect thereto, since the District Court expressly found to the contrary and its findings were not disturbed by the Court of Appeals, although respondent urged they were error.

V.

The Subject-Matter of the Divisional Patent No. 1,967,195 Was Not Dedicated to the Public or Abandoned (Resp. Br. p. 12).

Respondent contends that because the specific reference to the creation of heat by preheating the cork was cancelled from the specification of the parent patent the method was abandoned. The District Court rejected this contention also, saying (R., 2095):

> "It is true as contended by the defendant, the description of preheating which was originally contained in this application was cancelled by amendment, on December 3, 1930, but it is also true that at the time this description of the 'preheating' procedure was cancelled, Warth had on file a divisional application, Serial No. 494,201 which had been filed on November 7, 1930, *prior to the date of cancellation of the descriptive matter from the parent case.* From this divisional application, a second division Serial No. 664,410, was filed on April 4, 1933, containing precisely the three claims in suit and the patent issued, after an interference on this application. Therefore, Warth had in the Patent Office a complete disclosure of this preheating, from January 7, 1927, when the parent application was filed, until April 4, 1933, when the application resulting in Warth Patent No. 1,967,195 in suit was filed. *The subject matter was not abandoned, as suggested by defendant, but was specifically reserved by continuous inclusion in the divisional application, and later in the second division.* This has been approved *and is the usual practice. Writer* v. *Kiwad*, 63 Fed. (2d) 259."

The above finding was not modified by the Court of Appeals. Moreover, the respondent's argument for abandon-

ment overlooks the fact stated in the appendix to the brief accompanying the petition (p. 32), that when the specific reference to creating heat by preheating the cork was cancelled, there was substituted the *broader* expression which includes preheating, namely, that the invention is "*to utilize at the time of assembly both heat and pressure to unite the spot to the cork.*" (R., p. 714, l. 47.) It is not denied that the District Court correctly held (R., 2081) that "the sole purpose of preheating the cork * * * is to create heat which will be available at the instant the spot is deposited," *i. e.*, at the time of assembly. Certainly, the substitution of the broader statement (use of heat) for the specific (use of heat obtained by preheating the cork) which is included within the broad, should not be interpreted as an intent to abandon the specific.

It is evident, therefore, that the patentee adopted the only procedure possible in order to avoid any inference of abandonment, namely, (1) he cancelled the subject-matter so that it would not appear in the issued patent as an unclaimed part of its disclosure, (2) he substituted a *broader* statement when he cancelled the specific explanation of the way heat should be produced, and (3) he embodied the preheating description in a divisional application filed before the cancellation of the disclosure from the parent application.

Respondent contends (Br., p. 15) that the divisional patent application filed in 1933 is not entitled to either the filing date (November, 1930) of the application filed before the parent patent issued or to the 1927 filing date of the parent patent, notwithstanding the fact that the disclosures of the three applications were identical.

Respondent's first reason (Br., p. 15) is that, when the parent patent issued, its file showed that the description of preheating had been cancelled. But this contention overlooks the fact that before cancellation of the specific disclosure the same had been embodied in the divisional application filed in November, 1930. This is the only way an

applicant can reserve matter cancelled from a pending application.

Respondent's second argument for abandonment is that the 1933 divisional application should not be given the filing date of the 1930 application, and, therefore, cannot attach through the latter to the 1927 case. This argument is based upon the statement that the 1930 application did not *claim* a method but merely the strip material used in the method. The contention completely overlooks the express ruling of this Court in *Chapman* v. *Wintroath* that it is immaterial whether the invention of a divisional application be *claimed* in a parent application. Moreover, although the 1930 application contained only a disclosure and not a claim to the method, the specification states at the outset (R., 1949):

> "This invention relates to a method of producing closures of the type in which a sealing disc has a facing.
>
> This application is a division of my copending application, Serial No. 159,743, filed January 7, 1927."

The specification of the 1930 case is a copy of the parent application filed in 1927. It is thus apparent that Warth, instead of abandoning the specific preheating disclosure cancelled from the parent application, expressly reserved the same by embodying the identical description in the 1930 divisional case. The District Court so found and the Court of Appeals did not disturb the finding, although respondent urged error.

VI.

The Petition Raises No Question of Fact as to the Parent Warth Patent Reissue 19,117.

It is not correct, as alleged by the respondent (Br., p. 12), that the petition asks this Court to review the finding of non-infringement by the Court of Appeals. The reissue patent is involved only collaterally in the second question presented. The petition does not present the issue of in-

fringement. It raises only the question whether, in view of the *apparent* scope of the claims reasonably believed by the petitioner to dominate broadly the more specific invention of the divisional patent, petitioner is entitled to the benefit of such apparent scope as an excuse for the delay in presenting the more specific claims in the divisional patent. Whether the Court of Appeals was right or wrong in reading a limitation into the claims of the reissue, is not raised by the petition. The sole issue in the second question is whether the petitioner showed lack of diligence in failing to anticipate that the limitation would be incorporated in the claim by construction.

Here, we simply emphasize that *respondent has not disputed the facts on which the second question is based,* namely:

1. That the Court of Appeals *did* read into the reissue patent claims a limitation (heated plunger) which was not a part of the originally filed disclosure, and hence could not have been an essential or claimed part of the invention since an applicant cannot claim specifically anything which is not originally described. (*In re Mraz,* 36 App. D. C. 435.)

2. That the parent patent claims on their face are reasonably susceptible to an interpretation dominating the divisional patent subject-matter, as held by the District Court and

3. That petitioner reasonably relied upon the claims as covering broadly the divisional patent subject-matter.

Obviously, therefore, the petition presents no issues of fact or question of infringement involving the parent (reissue) patent. That patent is involved solely on points of law based on the above undisputed facts, as explained in the petition (pp. 7-9) and in the brief (pp. 26-28).

The decisions cited by respondent on the question of excuse (Resp. Br., p. 29) are not in point, since they relate

solely to the question of "inadvertence, accident or mistake" which must be shown in support of an application for a reissue patent. There were no facts involved in any of the cases cited comparable to those here presented, and, therefore, the decisions do not conflict with the ruling of the Circuit Court of Appeals for the Sixth Circuit in *Wagenhorst* v. *Hydraulic* (Pet. pp. 8, 26) to the effect that delay in presenting specific claims in a divisional application may be excused by the reasonably apparent broad scope of claims in a parent case, regardless of the finally determined scope of such claims.

Respectfully submitted,

ARGUMENT

CHAPTER I—THE QUESTION OF LACHES.	
Point I. The Court of Appeals Should Have Accorded the Warth Divisional Patent the Benefit of the Filing Date of the Second (1930) Application and Also of the Filing Date of the Original Warth Application Under the Rule Established by this Court in *Chapman* v. *Wintroath*, 252 U. S. 126.	14
Point II. In the Absence of Intervening Rights More Than Two Years Before Claims Are Presented in a Divisional Application, No Excuse for Delay is Required by the Decision of this Court in *Webster* v. *Splitdorf*, 264 U. S. U. S. 463	16
Point III. Petitioner's Own Use of the Warth Divisional Patent Invention Does Not Invalidate the Patent	22

Page

CHAPTER II—THE QUESTION OF EXCUSE FOR DELAY.

Point IV. If Warth's Delay in Specifically Claiming Preheating Requires an Excuse, it is Found in the Fact that the Parent Patent Claims (*a*) Do, in Fact, Cover and (*b*) Were Reasonably Believed to Cover the Subject Matter of the Divisional Patent Claims 24

A. It is Sufficient Excuse that the Parent Patent Claims Do Cover Generically the Preheating Method of the Divisional Patent 26

1. The language of the parent patent claims clearly covers applying heat *to the spot* by *either* a heated punch or a heated cork cushion 27

2. The file of the parent patent shows that no amendments were made which justify reading into the claims the "heated punch" limitation 29

3. The Court of Appeals' construction of the claims is inconsistent with the evident intent of the patentee and deprives him of protection for his actual invention 31

B. It is Sufficient Excuse that Warth Reasonably Believed that the Parent Patent Claims Cover the Subject Matter of the Divisional Patent Claims and Acted in Accordance With that Belief 33

Summary as to Excuse for Delay 34

Point V. The Grant of the Divisional Patent is Not Inconsistent with a Broad Interpretation of the Parent Patent Claims 36

IN THE

Supreme Court of the United States

No. 72

OCTOBER TERM 1937

CROWN CORK & SEAL COMPANY, INC., *Plaintiff-Petitioner*,

v.

FERDINAND GUTMANN & COMPANY, *Defendant-Respondent*.

BRIEF FOR PLAINTIFF-PETITIONER.

OPINIONS OF THE COURTS BELOW.

The opinion of the Circuit Court of Appeals is reported in 86 F. (2d) 698, and will be found in this record at Volume III, pp. 1830, 1834.

The opinion of the District Court is reported in 14 Fed. Supp. 255, and will be found in this record at Volume III, pp. 1767, 1784, 1796.

JURISDICTION.

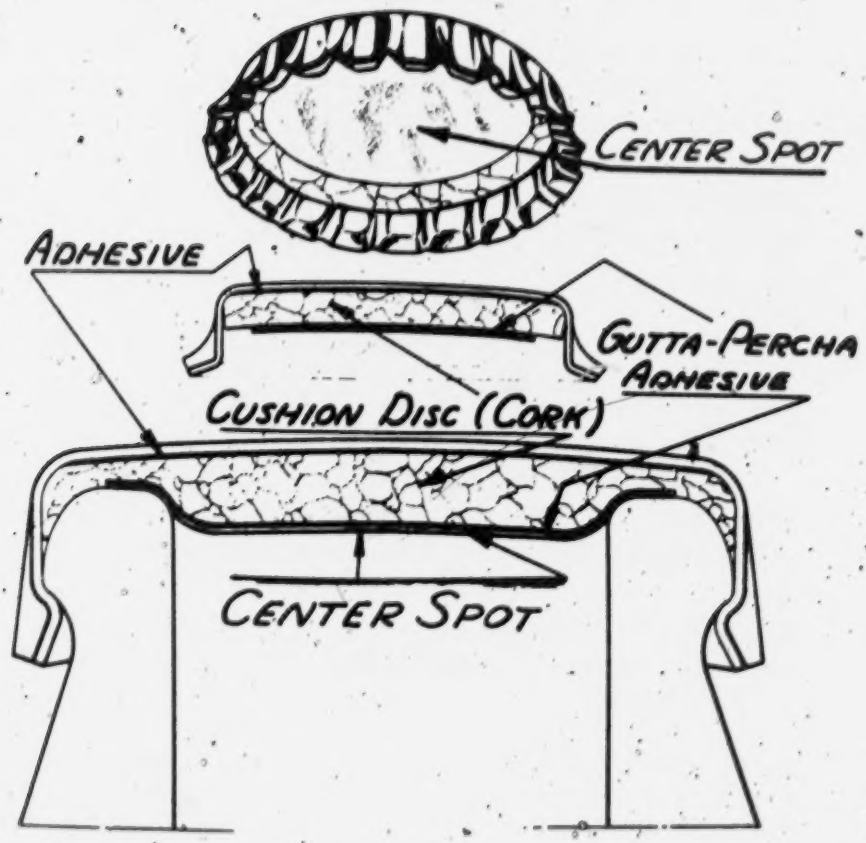
This case is here on a writ of certiorari to the Circuit Court of Appeals for the Second Circuit under the provisions of United States Code, Title 28, Section 347. The writ was granted on October 11, 1937.

STATEMENT OF THE CASE.

This is a patent suit brought by petitioner to enjoin infringement of two[1] Letters Patent, namely, Warth Reissue Patent No. 19,117, dated March 20, 1934 (R. p 547), hereinafter identified as the "parent" patent, and Warth patent No. 1,967,195, dated July 17, 1934 (R. p. 552), hereinafter identified as the "divisional" patent.

The patents cover methods for applying a small disc of foil or paper, known as a "center spot", to the cork cushion discs of crown caps used for sealing high pressure beverages, such as beer and ginger ale. The center spot is united to the cork disc by a thermoplastic (heat softenable) adhesive, such as gutta percha.

The center spot protects the cork cushion from the sealed liquid in the manner illustrated in the opposite sketch. The spot must be centered so that its edge extends over only a portion of the width of the bottle lip, thus leaving the cork around the spot exposed for direct engagement with the lip. Exact centering of the center spot is essential to insure uniform sealing engagement of the outer edge of the lip directly with the cork around the lip, and also uniform engagement of the inner edge of the lip with the center spot to protect the sealed beverage from the cork.



The Manufacture of Center Spot Crowns.

Closures having center spots adhesively united to the cushion disc had been known for years prior to the inventions in suit, but, aside from petitioner's own manufacture by its so-called "slide" machine,[2] no success had attended efforts to manufacture such a closure commercially. The problem was to adhere the spot securely at *high speed* and *accurately center it;* otherwise, the crown could not be sold in competition with other closures. An impermanently or

[1] Three other patents before the Court of Appeals are not involved here.

[2] Described in the Appendix, pp. 41, 42.

CENTER SPOT CROWN CAP

BLANK

PAGE

inaccurately-centered spot results in spoilage of the bottle contents.

Attempts had been made to adhere center spots with liquid-softened adhesives, but without success.[3] Experienced inventors had worked for years in developing and patenting machinery, but abandoned their efforts after admitted failure (R. pp. 129, 130, 344, 355).

As early as 1917, petitioner began manufacture of center spot crowns by the use of gutta percha, a thermoplastic adhesive. It used its so-called "slide" machine which was able to produce only from fifty to sixty closures a minute (R. p. 371).

This cumbersome machine presented many difficulties (R. pp. 370, 371) and the machines were subjected to continuous experiments (R. p. 371) over a period of about eight years. They were scrapped when the Warth method was developed.

The Warth Patents in Suit.

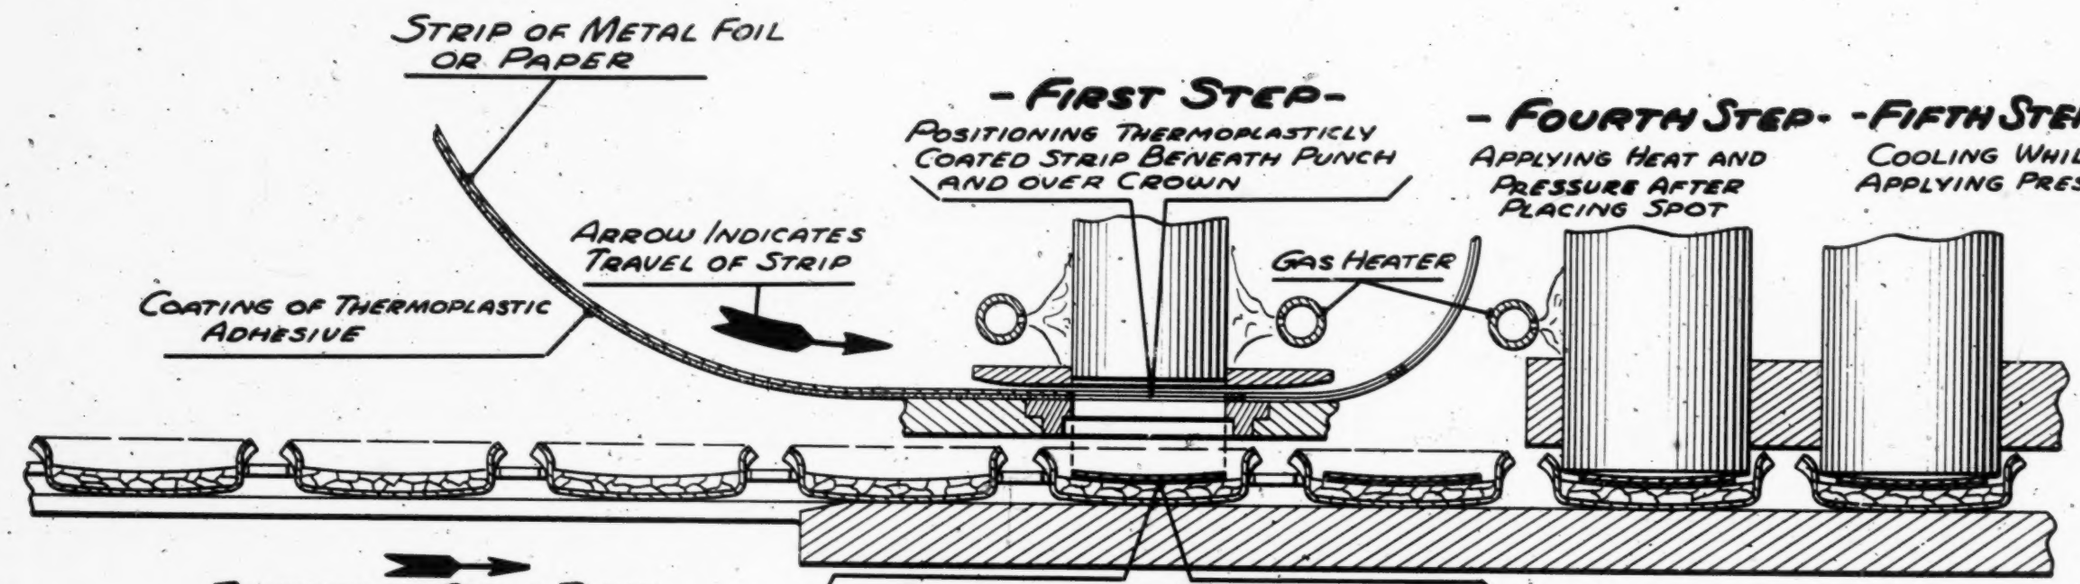
These patents disclose the method which has been used by petitioner since at least as early as 1927 (R. p. 1802) and which, as the District Court found (R. p. 1785), enabled petitioner to increase its production from less than *sixty* closures per minute for each unit by the old slide machine, to over *five hundred* closures per minute for each unit employing the Warth method. The patents describe the only method used today in the manufacture of crowns (R. p. 68) in which a center spot is adhesively united to the cork.

---

[3] McManus patent No. 1,402,780 (R. p. 1177) and Alberti patent No. 1,401,300 (R. p. 1205). McManus was unable to manufacture at a speed higher than *forty* a minute (R. p. 344) and with about *ninety per cent defective closures.* Alberti's efforts never passed the experimental stage (R. p. 355). The District Court found (R. p. 1787) that "Men skilled in the art had long sought by various methods to accomplish what Warth teaches * *".

The Warth Patent Reissue 19,117, March 20, 1934.

This patent discloses Warth's generic method which briefly is as follows: He positions a strip of spot material coated with non-tacky thermoplastic adhesive immediately above a traveling line of crowns and beneath a punch. The descent of the punch cuts out a spot and carries it directly down against the cork disc of a crown, heat being supplied to the spot *upon or at the instant of its contact with the cork to soften and make the adhesive tacky.* In this way, heat and pressure are applied simultaneously to the spot at the instant of its assembly with the crown, thus insuring instantaneous adherence of the spot in its exactly-centered position. After such assembly and adherence, the crown moves to the next stage where again it may be pressed with a heated plunger. Then the spot is held under pressure while it is permitted to cool. Claim 3[4] of the reissue patent is typical of the two claims (1 and 3) in suit and describes the generic method in formal language.



It will be noted that the claim does not specify any particular way of supplying the heat to the adhesive except that it must be supplied to the spot (1) simultaneously with pressure, and (2) "upon assembly", *i. e.,* at the instant the spot is deposited on the cork.

---

[4] The improved method of manufacturing caps of the type having an interior disc of cushion material provided on its exposed face with a center spot, which comprises providing spot material in strip form having one surface formed of an exposed continuous coating of water resistant adhesive which is normally hard at room temperature but becomes tacky upon the application of heat and having another surface to be exposed to the contents of a capped container, cutting from said strip a facing spot having one surface completely coated with said adhesive with a cap disposed beneath the portion of the strip from which the spot is cut, whereby the cutting operation positions the spot upon the cushion material with the coating between the spot and the cushion material, and upon assembly applying simultaneously to the spot pressure and sufficient heat to render the adhesive tacky, thereby causing the spot to adhere to the cushion material and thereafter permitting the adhesive to cool and harden while subjecting the assembled unit to pressure.

While the specification as originally filed, had fully disclosed the Warth generic method and had suggested various instrumentalities suitable for performing that method, no drawing was originally filed. In the prosecution of the application, the Patent Office required a drawing (R., p. 1253) of some mechanism suitable for carrying out the invention and it was supplied. Since the invention being claimed was a method, Warth needed to show, and all that he did show was some suitable mechanism by which his method could be performed.

For applying both heat and pressure to the spot at the time of assembly, Warth selected and depicted in his drawing, merely for illustrative purposes, a simple heated punch as part of what he referred to as "a suitable mechanism".

The Warth generic method, as it would be carried out with this illustrated "suitable mechanism", is shown by the drawing opposite this page.

The Warth method is essentially different from that of the old slide machine which it superseded and, as the District Court said (R. p. 1790), the combination of steps in the Warth method are not "found in the plaintiff's first old slide machine".

A description of the slide machine and the essential differences between it and the Warth method, will be found in the appendix, pp. 41, 42.

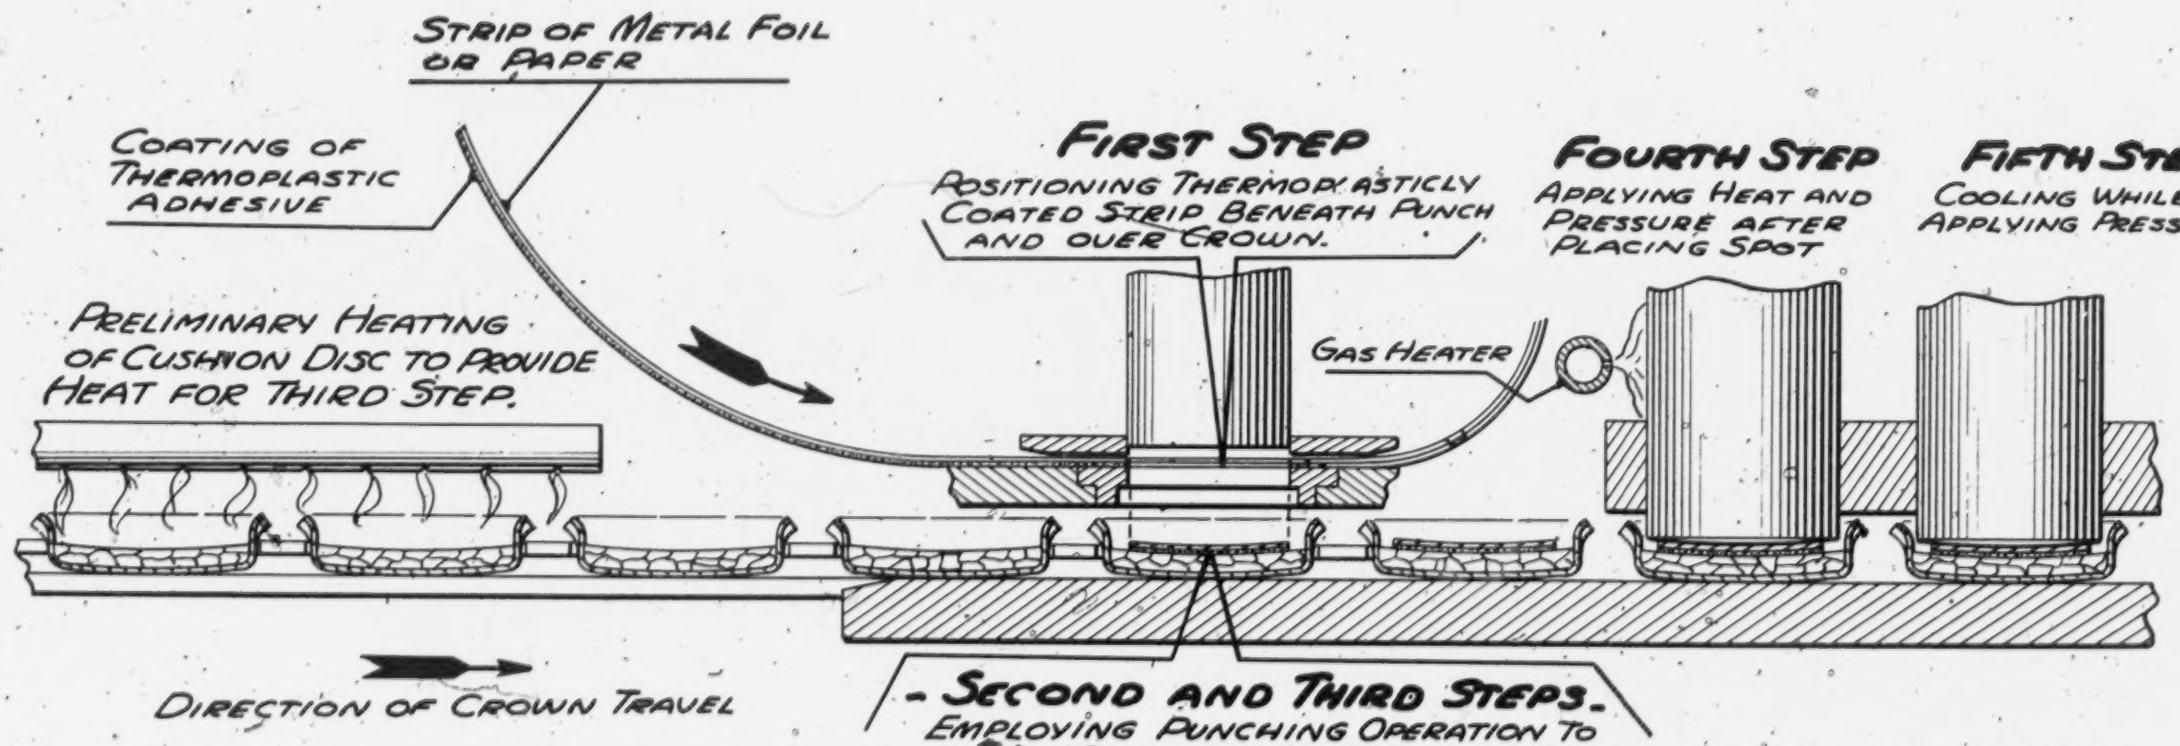
The Warth Divisional Patent No. 1,967,195, July 17, 1934.

In the generically claimed method of the parent patent, there was no limitation as to the manner in which heat was to be gotten to the spot, so long as it was at the instant of assembly with the cork cushion and simultaneously with the application of pressure by the punch. On the contrary, Warth's divisional patent is directed to a *particular way* of applying the heat to the spot. The divisional patent is, therefore, related to the parent patent as a specie is to its genus.

The method described in the divisional patent is illustrated in the drawing opposite this page. The cork discs in the crown shells are heated from above by gas jets as they advance to the spotting punch. When the assembled crowns with their preheated corks reach the punch and a spot is punched out and pressed against a cork, the heat stored in the cork passes to the adhesive simultaneously with the pressing of the spot on the cork. Consequently, at the instant of assembly, the adhesive is made tacky and this, with the pressure, causes the adherence of the spot in its exactly centered position. Thereafter, the crown may be subjected to further heat and pressure and then is cooled under pressure as described in the parent patent.

This particular way of heating the adhesive has an advantage over other ways, such as the use of a heated punch, in that less careful control of the heat is required (R. p. 412).

The claims of the divisional patent, of which claim 3[5] is typical, are limited to this specific mode of heat application to the spot by the phrase "heating the pads in the caps". This language also distinguishes the claims of the divisional patent from those of the parent patent for Warth's generic invention, since the claims of the parent patent do not specify any particular method of applying the heat to the spot at the instant it is deposited.



---

[5] The method of assembling linings for sealing pads in receptacle closure caps, consisting in providing caps with sealing pads therein and a web of lining material arranged with an adhesive surface non-viscous at normal temperature, *heating the pads in the caps*, severing the linings from the web of lining material and assembling the linings as they are severed from the web in the caps with the adhesive surface in contact with the heated pads to render the adhesive viscous and effect adhesion of the linings to the pads, then placing the linings in the caps under heat and pressure to effect an intimate adhesion between the linings and pads, and then placing the linings assembled in the caps under pressure during the cooling thereof.

The History of the Applications for Warth's Parent and Divisional Patents.

The parent patent (Re. No. 19,117) is a reissue of Warth patent No. 1,788,260, dated January 6, 1931, and filed January 7, 1927 (R. p. 1061). The propriety of this reissue is not questioned.

Admittedly the original application disclosed the preheating of the cork claimed in the divisional patent and the preheating disclosure was constantly before the Patent Office in the form of a pending application from the date of filing of the parent application until the issuance of the divisional patent here in suit.

On November 7, 1930, and while the original application was pending, Warth filed a second application (R. p. 1668) with a specification identical with that of the original application. *This second application described, but did not claim, the preheating invention of the divisional patent.* It was filed as a result of a Patent Office requirement (R. p. 1250) that another feature[6] of the original application disclosure be covered in a separate patent.

As has been said, Warth's parent application, as filed, had no drawing. While the application was pending, the Patent Office required Warth to file a drawing to illustrate devices by which his method could be carried out. He did this, electing to show, as a means for supplying the heat to the spot, a simple heated punch, thus describing *another* way of applying the heat to the spot in addition to his original description of preheating the cork.

At the time he filed this illustrative drawing Warth cancelled from his parent application, *but not from the second application which had already been filed,* the reference to preheating the cork and substituted the following broad statement as to the heating step of his method and as to the purpose of the newly-filed drawing (R. p. 1272, l. 11 *et seq.*):

[6] The thermoplastically-coated strip material used in the method.

> "The preferred method of applying the material to the cap is to utilize, at the time of assembly, both heat and pressure to unite the spot to the cork or cushion material * * *.
>
> "In Figures 3 and 4, there is shown a suitable mechanism for applying the disc and adhesively uniting it to the cork insert at the time the strip is punched * * *".

The cancellation from the original specification of reference to preheating the cork, after having inserted it in a copending divisional application, was in accord with a customary practice, as the District Court said (R. p. 1800):

> "The subject matter was not abandoned, as suggested by defendant, but was specifically reserved by continuous inclusion in the divisional application, and later in the second division. This has been approved and is the usual practice. *Writer* v. *Kiwad,* 63 Fed. (2d) 259".

After the parent patent (1,788,260) issued on January 6, 1931, and while the second application was pending, a patent issued to one Johnson (No. 1,852,578, R. p. 575) with claims covering specifically the "preheating" step which Warth had described in his original application and which was described in his then still-pending second application.

The Patent Office should have placed Johnson's application (R. p. 676), *filed more than two years after Warth's original application,* in interference[7] with the Warth's original application by suggesting to Warth, Johnson's allowed claim 35[8] (R. p. 713, quoted in Appendix, p. 45). That

---

[7] U. S. C. Title 35, Sec. 52, (R. S. Sec. 4904) and Rule 96 of the Rules of Practice. (See Appendix, p. 43.)

[8] Suggestion of an allowed conflicting claim of a later applicant to an earlier applicant is the procedure under Rule 96 (Appendi p. 43) for declaring an interference. Claim 35 of the Johnson application had been allowed on September 10, 1930 (R., p. 717) several months before the Warth original application was allowed. The conflict between the parent Warth and Johnson applications is evident not only from the subsequent rejection of the Johnson

this claim read upon the Warth application disclosure is evident from (1) the subsequent rejection of Johnson's claim on the Warth parent patent after the latter issued (R. p. 725), and (2) the cancellation of the claim by Johnson (R. p. 726) in response to the rejection.

But only because the Patent Office overlooked the conflict between the two applications, no interference was declared. Consequently Warth had no knowledge, while his original application was pending, of Johnson's conflicting preheating claims which also stood allowed in the Johnson application. If an interference had been declared, then the issue of inventorship priority would have been determined while Warth's original application was still pending. Due to this oversight on the part of the Patent Office, Warth obtained no notice of the necessity for claiming preheating specifically until the Johnson patent later came to his attention. As soon as the Johnson patent came to Warth's attention, he copied[9] the Johnson preheating claims by filing on April 4, 1933, a division of his then-pending second application and obtained an interference in which the Patent Office held Warth to be the prior inventor.

Warth had broadly claimed the invention (R. p. 1835) in his parent patent application and had had continuously on file in the Patent Office, first in his original application and then

---

claim (35) on the Warth patent, but also from a comparison the Johnson claim (Appendix, p. 45) with the Warth patent claims, one of which is quoted p. 4 *ante*. This comparison shows that the two applicants were claiming substantially the same invention, the condition prescribed by the Statute and Rule (R. S. Sec. 4904 and Rule 96) for declaring an interference. The Johnson application had been pending in Division 14 (R., p. 714) and the Warth application (R., p. 1253) in Division 56, where it was endorsed for allowance (R., p. 1275), although it was transferred to Division 14 for the formal allowance (R., p. 1288).

[9] The Johnson patent claims were copied within a year after the Johnson patent had issued, and, therefore, within the two years allowed by *Chapman* v. *Wintroath*, 252 U. S. 126.

in his second application, a complete disclosure of the subject-matter covered by the interference claims. Because of this *continuity of disclosure by Warth,* the Patent Office gave the divisional application the benefit of the filing date of the second (1930) application, which disclosed but did not claim preheating, and through the latter the benefit of the filing date of the original application of which the second was admittedly a division. Accordingly the claims of the Johnson patent were awarded to Warth as the prior inventor and are now the claims of the Warth divisional patent here in suit.

This was all in accordance with the Patent Office practice as it has existed for over fifty years. The practice was recognized and approved by this Court as far back as *Smith et al.* v. *Sprague,* 123 U. S. 249, 250, and its propriety was reiterated by the Commissioner of Patents in *Hopfelt* v. *Read,* 1903 Commissioner's Decisions, 319, 321. See the quotation from the latter decision in the Appendix, p. 48.

The Decisions of the Lower Courts.

The District Court for the Eastern District of New York (Campbell, J.), found both patents valid and infringed. The Circuit Court of Appeals for the Second Circuit (Manton, J., dissenting) reversed the decree, holding that the parent patent was not infringed and that the divisional patent was invalid because of laches in filing the application.

Grounds Upon Which the Circuit Court of Appeals Decision is Based.

(1). Reversing the finding of the District Court (R. p. 1805) as to the divisional patent, the Circuit Court of Appeals held that the mere lapse of two years and four months between the grant of the parent Warth patent and the presenting of specific claims to preheating in Warth's divisional application, invalidated such claims in the absence of a legal excuse, *notwithstanding the fact that during this*

interval no intervening bar had arisen.[10] The subject-matter of the specific preheating claims had not been disclosed in any patent or publication, and had not been in public use by others for two years or more before the claims were presented and, therefore, there arose no bar to the divisional patent analogous to the bars created by the statute (R. S. Sec. 4886, Appendix, p. 44). The Court of Appeals said (R. p. 1837):

> "The disclosure, however, had been continuously on file since January 7, 1927; [the filing date of the parent patent] and so the plaintiff contends that it is entitled to that filing date. We do not so understand the law, as laid down in Webster Co. v. Splitdorf Co., 264 U. S. 463, 471, 44 S. Ct. 342, 344, 68 L. Ed. 792. Prima facie the two-year time limit applies to divisional applications, and an applicant who waits longer before claiming the invention disclosed in his application must justify his delay by proof of some excuse. No such excuse appears here."

(2). The Court of Appeals refused to excuse Warth's delay in presenting preheating claims (*a*) because it held that the parent patent claims are not broad enough to cover preheating and (*b*) because it declined to accept as an adequate excuse the fact that the claims of the parent patent *were intended and believed to be*, and *apparently* are, broad enough to comprehend in their scope the specific preheating

[10] The Court of Appeals referred to the issuance of the Warth parent patent more than two years before the divisional patent claims were asserted, but the parent patent contained no description of the method of the Warth divisional patent and hence was not a printed publication. The Court of Appeals also referred to the Johnson patent, but this issued less than a year before the claims were asserted by Warth and hence is not a bar under the rule of this Court in the *Chapman* case, *supra*. Respondent's use of the invention was also urged as being more than two years prior to the Warth divisional application, but was found by the District Court not to anticipate (antedate) the filing date of the Warth divisional patent (R., p. 1803) and this finding was not disturbed by the Court of Appeals, although respondent strenuously urged that such finding was error.

method. The Court of Appeals also disregarded the fact that Warth had maintained the disclosure of preheating continuously on file in a pending and regularly prosecuted application and had asserted his inventorship as soon as the Johnson patent came to his attention, and the further fact that Warth failed to receive actual notice of Johnson's claim to inventorship while the parent Warth application was pending because the Patent Office failed, through oversight, to declare an interference between the Warth and Johnson applications, as required by the Statute and the Patent Office Rule.

(3). In refusing to hold the Warth parent patent claims sufficiently broad to cover preheating and therefore to constitute an excuse for Warth's delay, the Court of Appeals read into and restricted the claims of the parent patent to the use of a "heated plunger" as a means for applying heat to the spot upon or at the instant of assembly. In this, the Court of Appeals did what this Court said in *Altoona* v. *American Tri-Ergon,*[11] 294 U. S. 477, 487, should not be done; that is, included in a claim "parts of the specifications, or of other claims, which the patentees failed to include in it", and it also disagreed with the District Court which had said (R. p. 1790-91):

> "The claims in suit are not limited to the application of heat directly to the punch, and they are not so limited by the drawing offered by Warth in the prosecution of his patent, simply for the purpose of illustrating a suitable means for effecting the simultaneous application of heat and pressure at the instant of depositing the spot.
>
> "The prior art did not, nor do I find anything in the records of the Patent Office actions which limit the claims in suit to producing in any particular way the heat which is utilized at the instant of assembly."

---

[11] Also in *Smith* v. *Snow,* 294 U. S. 1, 11; *Smith* v. *Hall,* 301 U. S. 216, 220.

SPECIFICATION OF ERRORS.

1. The Circuit Court of Appeals for the Second Circuit erred in holding that a two year time limit for presenting claims in a divisional application, as announced by this Court in *Webster Co.* v. *Splitdorf Co.*, 264 U. S. 463, is applicable in the present case and *in the absence of adverse public use, patenting or publication more than two years before the presentation of the claims.*

2. The Circuit Court of Appeals for the Second Circuit erred in ignoring the *apparent* and *intended* breadth of the claims in the parent patent and in not holding that, since these claims were **believed** and **intended** to be, and **apparently are**, of a breadth to cover the subject-matter of the divisional patent, the delay in presenting the claims in the divisional patent is excused.

3. The Circuit Court of Appeals erred in failing to find the parent patent claims sufficiently broad to cover preheating and to excuse the delay (because it read into the claims of the parent reissue patent a part of the specification which the patentee did not include in the claims) and in refusing to accept the claims as written, namely, to cover the application of heat at the instant of assembly whether it be applied (*a*) by a heated punch, as illustrated in the patent, or (*b*) by a heated cork cushion, as initially described in the application, or (*c*) partly by a heated punch and partly by a heated cork, as the method is practiced by both petitioner and respondent.

4. The Circuit Court of Appeals erred (a) in reversing the District Court which had adjudicated the patents in suit as valid and infringed; and (b) in issuing its mandate directing the said District Court to enter a decree dismissing petitioner's bill of complaint.

ARGUMENT.

Chapter I—The Question of Laches.

POINT I.

The Court of Appeals Should Have Accorded the Warth Divisional Patent the Benefit of the Filing Date of the Second (1930) Application and Also of the Filing Date of the Original Warth Application Under the Rule Established by this Court in Chapman v. Wintroath, 252 U. S. 126.

The refusal of the Circuit Court of Appeals to accord to the Warth divisional patent the priority rights of the original or even of the second (1930) application directly conflicts with the decision of this Court in *Chapman* v. *Wintroath*, 252 U. S. 126, and *Overland* v. *Packard*, 274 U. S. 417.

In *Chapman* v. *Wintroath, supra*, this Court reiterated the rule that a divisional application is entitled to the benefit of the filing date of the parent application "with all its priority of right" for anything disclosed in the parent application, whether claimed in the parent application or not. This Court said:

> "To this we must add that not only have later or divisional applications not been dealt with in a hostile spirit by the courts, but, on the contrary, designed as they are to secure the patent to the first discoverer, they have been favored to the extent that where an invention clearly disclosed in an application, as in this case, *is not claimed therein but is subsequently claimed in another application, the original will be deemed a constructive reduction of the invention to practice and the later one will be given the filing date of the earlier, with all of its priority of right.* (Citing) *Smith & Griggs Manufacturing Co.* v. *Sprague*, 123 U. S. 249, 250; *Von Recklinghausen* v. *Dempster*, 34 App. D. C. 474, 476, 477."

Following the decision in *Webster* v. *Splitdorf*, 264 U. S. 463, this Court said in the *Overland* case, *supra*, that the priority rights of a divisional application should not be diminished by equitable considerations. Interpreting the earlier *Chapman* v. *Wintroath* decision, this Court said (at p. 426):

> "This court held [in Chapman v. Wintroath] that under Sec. 4886 of the Revised Statutes, as amended March 3, 1897, two years was granted in such a case before the right to file a divisional application had been lost. *The Court based its decision that the statutory period could not be reduced by equitable considerations or those of public policy* on the language which we have just quoted from Mr. Justice Brewer in his opinion in the *Telephone* case."

Our understanding of the rule thus established is that **an applicant has two years from the date of any intervening adverse right, analogous to the bars established by the Statute,**[12] **in which to present claims to subject-matter disclosed in any parent or prior application, whether claimed therein or not.**

In the case at bar, there was no adverse public use or printed publication of the preheating invention of Warth's divisional patent more than two years prior to the date he presented the claims of that patent. In the *Chapman* case, the Court stated that, where a patent has issued to another more than two years before its claims are copied by a divisional applicant, the lapse of such period *prima facie* bars the divisional applicant. Such an earlier patent to another is an intervening adverse right and is analogous to the two year bar established by the statute.

But, in the case at bar, the Johnson patent issued less than a year before its claims were copied by Warth in his divisional application. Consequently, the Court of Appeals for the Second Circuit overlooked the admonition of

[12] U. S. C. Title 35, Sec. 31 (R. S. Sec. 4886). See Appendix, p. 44.

this Court in the *Chapman* case (p. 135) with reference to a patent such as Johnson's that:

> "Such a prior patent is in no sense a bar to the granting of a second patent for the same invention to an earlier inventor, provided that his application is filed not more than two years after the date of the conflicting patent. The applicant may not be able to prove that he was the first inventor but the statute gives him two years in which to claim that he was and in which to secure the institution of an interference proceeding in which the issue of priority between himself and the patentee may be determined in a prescribed manner."

Warth acted in compliance with the above rule, copied the Johnson claims within one year from the date his patent issued, and was awarded the claims as prior inventor. Moreover, Warth's parent patent, as issued, contained no description of the preheating step, and was not a printed publication. Such a patent has been held not to be a bar even when it contains a description of the divisional patent invention.[13]

POINT II.

In the Absence of Intervening Rights More Than Two Years Before Claims Are Presented in a Divisional Application, No Excuse for Delay is Required by the Decision of this Court in Webster v. Splitdorf, 264 U. S. 463.

In the case at bar, the Court of Appeals extended the ruling of this Court in *Webster* v. *Splitdorf* beyond anything justified by that or any other decision of this Court, since it formulated a bar to divisional patents which has no basis, as such or by analogy, in the fundamental statute (R. S. Sec. 4886—Appendix, p. 44).

In the *Webster* case, this Court simply applied the doctrine of *Chapman* v. *Wintroath* to a case in which interven-

[13] *Folberth Co.* v. *Mayo Co.*, 292 Fed. 883, 894 (D. C. N. D. Ill.).

ing adverse rights analogous to those established by the Statute (R. S. Sec. 4886) had arisen more than two years before the claims were presented.

The facts of the *Webster* case briefly were: The original application for the Kane patent in suit was filed February 2, 1910. In 1915, Kane filed a divisional application, in the prosecution of which, on June 17, 1918, claims were presented to subject-matter *deliberately* not claimed, either broadly or specifically, in the original application, because Kane considered their subject-matter one merely of design.

These claims were presented five years after a complete disclosure of their subject-matter appeared in an issued Podlesaks patent and an equal length of time after the device had been in general public use by others.

This Court found "that Kane did not originally intend to assert" the claims, that the claims were "*broader* than those originally sought" and "that the delay was unreasonable, and, under the circumstances shown by the record, constitutes laches" by which Kane lost his right to a patent on the subject-matter of the late-presented claims.

We do not understand that this Court held in *Webster* v. *Splitdorf,* as stated by the Court of Appeals in the case at bar, that, in *any* case where there has been a delay of more than two years in presenting claims in a divisional application, such delay, *even in the absence of adverse public use or intervening rights,* invalidates the patent unless excuse be shown.

Other Courts of Appeal have held that the doctrine of *Webster* v. *Splitdorf* applies only in the presence of intervening adverse rights. See the quotations in the Appendix, (pp. 45-48) from *Utah Radio Products Co.* v. *Boudette* (C. C. A. 1st), 78 F. (2d), 793, 799, *Wagenhorst* v. *Hydraulic Steel* (C. C. A. 6th), 27 F. (2d), 27, 29, 30, *Wirebounds Patents Co., et al.* v. *Saranac* (C. C. A. 6th), 37 F. (2d) 830, 840, 841, and *Wirebounds Co.* v. *Saranac* (C. C. A. 6th), 65 F. (2d) 904, 905, 906.

The facts in the case at bar are not analogous to those in the *Webster* case. While here there was a delay of more than two years in presenting the claims specific to preheating, *yet here there had been no adverse public use of the invention before or during the two year period.*[14]

Nor had there been any disclosure of the invention in an issued patent or printed publication, except the Johnson patent No. 1,852,578 (R. p. 575), which issued *only a year* before the claims were asserted, and, therefore, well within the two year period allowed for copying the Johnson claims under the *Chapman* case, *supra.*

Moreover, since the Court of Appeals found (R. p. 1835) that Warth had broadly claimed the subject-matter of the divisional patent during the pendency of his parent patent, there was no *deliberate* failure, as in the *Webster* case, to claim the subject-matter prior to claiming it specifically in the divisional application.

Further, Warth *believed* (p. 33, *infra*) he had covered the invention of the divisional patent by the claims issued in the parent patent. Certainly the claims of the parent patent are at least *apparently* of such breadth (pp. 26-36, *infra*) and it is petitioner's position that they are, *in fact,* of such breadth. The District Court so held (R., pp. 1791-92), but the Court of Appeals erroneously gave the claims a narrow construction, as discussed *infra,* p. 27, *et seq.*

In short, the Court of Appeals held that Warth's unintentional delay of two years and four months in claiming the preheating method specifically, *absent intervening*

---

[14] Respondent did attempt to prove use of preheating by itself and others more than two years prior to the divisional patent application, but the District Court held (R., p. 1803):

> " * * * the defendant has not proved any use of the preheating method, to anticipate the filing date of the first divisional application, November 7, 1930, or the filing date of the second divisional application, April 4, 1933".

This finding was not disturbed by the Court of Appeals, and, therefore, should be accepted by this Court under the rule of *Adamson* v. *Gilliland,* 242 U. S. 350, 353.

rights, is the equivalent of the eight year *deliberate delay and failure* to claim an invention, considered in the *Webster* case, where *public rights in the meantime had accrued.* On this finding, the Court of Appeals has denied Warth the benefit of the general rule that a divisional patent relates back to the filing date of its parent patent.

The error as well as the extreme harshness of the rule announced by the Court of Appeals is evident from the fact that it applies to divisional applications a two year time limit which is not imposed upon them by the fundamental statute.[15] The statute bars the allowance of a patent *only if there has been a printed publication, public use or sale of the invention more than two years before the filing date of the application.* The rule established by the Court of Appeals for the Second Circuit requires an excuse for delay and *prima facie* bars a patent, whether statutory bars, as such or by analogy, exist or not. The rule, as applied in the case at bar therefore, is in conflict with the statement of this Court in *United States* v. *American Bell Telephone Co.*, 167 U. S. 224, 247, that "No Court can disregard any statutory provisions in respect to these matters on the ground that, in its judgment, they are unwise or prejudicial to the interests of the public."

In the case at bar, aside from the admitted use of the invention by petitioner,[16] the District Court and the Court of Appeals found no use of the invention or public disclosure thereof more than two years before the filing of the divisional application.

Consequently, if the rule of the Court of Appeals is correct, a divisional application is not entitled even to the benefit of its own filing date if there has been a two-year delay in claiming its subject-matter. This is true since the District Court found (footnote p. 18; *ante*) that respondent had not proved prior use of the divisional patent invention and there was no contrary finding by the Court of Appeals.

---

[15] U. S. C., Title 35, Sec. 31, (R. S. Sec. 4886), Appendix, p. 44.

[16] See discussion, p. 22, *infra.*

To hold a divisional patent invalid in the absence of proof of prior use, as the Court of Appeals did in the case at bar, certainly diminishes the patentee's rights under the statute,[17] and is plainly inconsistent with the decision of this Court in *Overland* v. *Packard* (p. 15, *ante*).

The Court of Appeals found no statutory bars and refers only to the issuance of the parent Warth patent and to the issuance of the Johnson patent during the two year period. But the parent Warth patent, as issued, *contained no description of the preheating invention*, and hence was not a printed publication of the invention or an *adverse* patent or right. The Johnson patent issued *less than one year* before Warth presented the preheating claims, and hence is not a bar, under the decision of this Court in *Chapman* v. *Wintroath* (p. 14 *ante*).

In the *Webster* case, this Court drew an analogy between the two year period allowed (*Chapman* v. *Wintroath*) for presenting claims in a divisional application, and a two year limitation for filing application for a broadened reissue patent. In each case, however, there is a definite occurrence analogous to the bars created by the Statute (R. S. Sec. 4886), from which the two year limit begins to run.[18] **We submit that the two year period announced in the Webster case should begin to run only when there has been some adverse intervening right analogous to the statutory bars, and that on this theory the doctrine of laches announced in the Webster case is based.**

The reasonableness of requiring a showing of intervening rights from which to date the two year period of laches announced in the *Webster* case is apparent from the fundamental theory of laches explained by this Court in

---

[17] R. S. Sec. 4886, Appendix, p. 44.

[18] The issued patent from which the claims are copied is a printed publication; in applying for reissue the original patent is a printed publication. Therefore, each is one of the bars specified in R. S. Sec. 4886.

Galliher v. *Cadwell*,[19] 145 U. S. 368, 372, 373, with reference to cases decided on laches:

> "They proceed on the assumption that the party to whom laches is imputed has knowledge of his rights, and an ample opportunity to establish them in the proper forum; that by reason of his delay the adverse party has good reason to believe that the alleged rights are worthless, or have been abandoned; and that because of the change in condition or relations during this period of delay, it would be an injustice to the latter to permit him to now assert them.
>
> * * * *
>
> "They all proceed upon the theory that laches is not like limitation, a mere matter of time; but principally a question of the inequity of permitting the claim to be enforced—an inequity founded upon some change in the condition or relations of the property or the parties."

A reading of this Court's decision in the *Webster* case shows that the Court based its application of the doctrine of laches on the theory that one should not be permitted to expand his claim "to the detriment of those who have, in consequence, been led to act as though it were abandoned". (*Webster* v. *Splitdorf*, p. 467). Obviously, if there are no intervening rights, there can be no question of inequity or change in the condition or relations of any parties, especially where, as here, the inventor from his original filing date has asserted claims which he believed, and which apparently do, cover the divisional patent invention. See pp. 26-36 *post*.

---

[19] And in other decisions therein cited.

POINT III.

Petitioner's Own Use of the Warth Divisional Patent Invention Does Not Invalidate the Patent.

Respondent did not contend before the lower Courts, nor did either Court find, that petitioner's admitted use of the preheating invention for some years prior to the filing of the Warth divisional application invalidates the patent. However, we will refer briefly to this point since it is raised before this Court in the case of *General Talking Pictures* v. *Western Electric* (No. 357).

Courts which have considered the question have held that a divisional patent is not barred by use by the patentee or his licensees. See *Wirebounds Patents Co.* v. *Saranac*, 37 F. (2d) 830, 841 (C. C. A. 6); *American Chain Co.* v. *Franklin New York Co.*, 34 F. (2d) 551 (E. D. N. Y.); *American Laundry Mchy. Co.* v. *Prosperity Co.*, 295 Fed. 819 (C. C. A. 2).

A contrary interpretation of the law would largely nullify the spirit and intent of the fundamental patent statute (R. S. Sec. 4886—Appendix, p. 44). Under the statute an inventor may publicly use his invention for two years before filing patent application. The courts have frequently commended inventors for taking advantage of this statute by subjecting the invention to thorough test, even in commercial use, as is often necessary, instead of rushing into the Patent Office with disclosures of untried and unperfected developments, and the importance of this statutory provision to the general public, as well as to inventors, has been emphasized.[20]

If it were the law that an inventor's own use, or use authorized by him, more than two years before the filing of a divisional application bars the issuance of a patent, no inventor could safely make his invention available to the public either before or even after he had filed an application, until it became certain that it would not be neces-

---

[20] *Elizabeth* v. *Pavement Company*, 97 U. S. 126, 137; *Kendall* v. *Winsor*, 62 U. S. 322, 328-329; *Agawam Company* v. *Jordan*, 74 U. S. 583, 607-608; *Joy* v. *Morgan*, 295 Fed. 931, 935, 936.

sary or desirable for him to file any divisional application to protect part of his original application disclosure.

Frequently, the requirement or the desirability for filing divisional applications does not arise until years after the original application for patent has been filed. Such was the situation which confronted the inventor in *Chapman* v. *Wintroath, supra,* where it was six years after the Chapman application was filed before it became apparent to Chapman or his attorneys that a certain phase of his initial disclosure should be claimed. That phase Chapman had to claim in a divisional application. The statute[21] encourages and requires a complete disclosure and the completeness of the initial application disclosure is ordinarily the reason for the filing of subsequent divisional applications, since the Patent Office will not permit the claiming in a single patent of inventions which are separately classified.[22]

To hold that a patent is barred by the inventor's own public use more than two years before the filing of a divisional application would compel him to anticipate all possible requirements or reasons for divisional applications. The necessity for many divisional applications arises from events which cannot be foreseen, such as the inadvertent issuance of patents to another, as in the *Chapman* case and in the case at bar, or changing of the Patent Office classification of patents which is constantly being revised. Consequently, if it were the rule that use by the inventor more than two years before filing a divisional application is a statutory bar, the inventor and the public would be deprived of the benefits of the fundamental statute (R. S. Sec. 4886) which permits and encourages public use and test of inventions for two years prior to the filing of application for patent.

---

[21] U. S. C. Title 35, Sec. 33, (R. S. Sec. 4888) Appendix, p. 44.

[22] For example, in 1934 and 1935, the last years records which were maintained by the Patent Office, approximately every eighth applicant for patent was required to file divisional applications to protect his full disclosure. In 1934, examination of applications resulted in 7162 requirements for divisions and in 1935, 7609 requirements.

CHAPTER II—THE QUESTION OF EXCUSE FOR DELAY.

POINT IV.

If Warth's Delay in Specifically Claiming Preheating Requires an Excuse, it is Found in the Fact that the Parent Patent Claims (a) Do, in fact, Cover and (b) Were Reasonably Believed to Cover the Subject Matter of the Divisional Patent Claims.

This Court said in the *Webster* case that more than two years' delay in presenting claims after an intervening right had arisen may be excused "by special circumstances, which show it to have been not unreasonable". In the case at bar, the Court of Appeals said (R., p. 1837):

> "* * * an applicant who waits longer [than two years] before claiming the invention disclosed in his application must justify his delay by proof of some excuse. No such excuse appears here".

Lower Courts have heretofore recognized, as an excuse for delay, the fact that the claims in the parent patent do, in fact, cover the later-claimed divisional subject matter.

In the case at bar, the Court of Appeals recognized this law and correctly stated the ruling and the reason for it as follows (R. p. 1837):

> "Had Warth chosen to retain in his parent application broad generic claims which might cover the preheating method, then indeed the Splitdorf rule might not be applicable. Carson v. American Smelting & Refining Co., 4 F. (2d) 463, 470 (C. C. A. 9). The delay would be excused since a patentee is not to be held at fault for failing to have divided his claims at an earlier date, merely because he might have, when instead he had elected to prosecute the broader claims of his original application. Hartford-Empire Co. v. Nivison-Weiskopf Co., 58 F. (2d) 701, (C. C. A. 6)."

It has also been held that a *seeming* broad scope of parent patent claims and the inventor's belief that they were of a scope broad enough to cover the later-claimed divisional subject matter, *even though he was mistaken*, is an excuse for delay in presenting specific claims. In *Wagenhorst* v. *Hydraulic Steel* (C. C. A. 6) 27 F. (2d) 27, 31, 32, the Court said:

> "It may be said, with some certainty as to original claim 2, and with some probability as to claims 1 and 3, that, if granted, they would have seemed to cover defendant's later structure, and might or might not have been construed in that way. The trouble was that with that construction they went beyond the applicant's device and reached the prior art. Wagenhorst's amended divisional claim restricted his claimed invention to the specific form of its concrete embodiment. This is a very different thing from the enlargement in the Webster Case".

See also *McGrath* v. *Burke*, 12 F. (2d) 161, 162 (App. D. C.) and *MacLaren* v. *Stoetzel*, 38 F. (2d) 125, 128, 129 (C. C. P. A.), in each of which delay in presenting specific claims was excused because the inventor *believed* he had covered the subject matter by the claims of an earlier patent or application, notwithstanding the fact that such belief was mistaken.

In the case at bar, the Court of Appeals found no excuse for Warth's delay. It refused to give him the benefit of the ruling of such decisions as the *Hartford-Empire* case (*supra*, p. 24) because of its erroneous conclusion that Warth's parent claims do not cover preheating. This conclusion was based on a plain error, as we show, *infra*, pp. 26-32.

The Court of Appeals also failed to give Warth the benefit of such rulings as that in the *Wagenhorst* and other cases cited (*supra*), because it ignored the fact that the parent patent claims, at the very least, *are susceptible of an interpretation broad enough to cover preheating.*

Hence, Warth's belief that they were of such broad scope and his reliance thereon were reasonable, and this brought him directly within the rule of the cited cases, as we show *infra,* pp. 33-36.

A. It is sufficient excuse that the parent patent claims do cover generically the preheating method of the divisional patent.

The District Court found that the parent patent claims should be interpreted to cover *any* way of utilizing heat simultaneously with pressure at the instant of assembly, whether by heated punch or preheated cork. The Court said (R. pp. 1790-91):

> "The claims in suit are not limited to the application of heat directly to the punch, and they are not so limited by the drawing offered by Warth in the prosecution of his patent, simply for the purpose of illustrating a suitable means for effecting the simultaneous application of heat and pressure at the instant of depositing the spot.
>
> "The prior art did not, nor do I find anything in the records of the Patent Office actions which limit the claims in suit to producing in any particular way the heat which is utilized at the instant of assembly."

The Court of Appeals did not disagree with the finding of the District Court that the claims, when broadly so construed, avoid the prior art; that is, are not anticipated, when so construed, either by petitioner's old slide machine or by any prior patent. The Court of Appeals simply refused to accord the claims the broad construction adopted by the District Court, solely because (a) it misinterpreted the language of the patent claims, and (b) it drew certain inferences from the cancellation of a reference to preheating just before the grant of the parent application and the withdrawal of claims broad enough to cover preheating but (a thing the Court overlooked) also broad enough to be rejected by the Patent Office as including the prior art.

1. The Language of the Parent Patent Claims Clearly Covers Applying Heat to the Spot by Either a Heated Punch or a Heated Cork Cushion.

Referring to that clause of the Warth claim which reads

> "and upon assembly applying simultaneously *to the spot* pressure and sufficient heat"

the Court of Appeals said (R. p. 1836) that this

> "clearly means *applying* the heat at the time of pressure, not pressure by a cold punch on an already heated crown". (Court's emphasis).

But, in saying this, the Court clearly overlooked the all-important words **"to the spot"**.

Warth's method, as stated in the claim, is concerned *only* with the time when the heat is applied **to the spot**, not when it may be applied to some other part of the crown. No matter at what point in its travel the non-spotted crown receives its heat, obviously **none of that heat can be applied "to the spot" until the spot is pressed against the heated crown.**

As a consequence of its overlooking the phrase "to the spot", the Court went on to say erroneously that the above-quoted clause of the claim *cannot* mean "pressure by a cold punch on an already heated crown", i. e., on a pre-heated non-spotted crown. Clearly, that operation is precisely one which the clause does cover, since in such an operation, the heat and pressure are applied simultaneously "to the **spot**" only upon or at the instant of its assembly with the crown, exactly as the claim specifies.

Because of this erroneous and strained construction, the Court said (R. p. 1835) that the claims must be limited to mean "that the heat and pressure are applied by the cutting punch". By thus disregarding the words "to the spot", and reading into the method claims a mechanical limitation, the Court has rewritten the claims as the Patent Office would not have permitted Warth himself to do, *since*

the heated punch was not part of his original disclosure and was added to the application disclosure during the prosecution of the application merely *as an example* of a way "to utilize at the time of assembly, both heat and pressure". *In re Dilg,* 25 App. D. C. 9, 11.

Even if the application had originally disclosed only the heated punch, nevertheless the claims would have covered preheating the cork, since, as the uncontradicted testimony shows, (R. p. 69), preheating is only another way, though a novel and important one, of

> "doing the same thing that Warth teaches in the reissue [parent] patent, that is utilizing the heat * * instantly at the time of assembly. It accomplished the same final result * * *".

Thus, a hot punch and a preheated cork function for the same purpose, namely, to transmit or apply heat to the spot at the instant of assembly, the difference being that, by the heated cork, the heat is applied from below and, by the heated punch, from above the spot. *Defendant actually uses both, because its heat is applied partly by the punch and partly by the cork* (R. p. 95, RDQ 282).

Moreover, the description of the heated punch (R. p. 550, l. 56 *et seq.*) is immediately preceded by the broad statement (R. p. 550, l. 46 *et seq.*):

> "The preferred method of applying the material to the cap is to utilize, at the time of assembly, both heat and pressure to unite the spot to the cork cushion material insert or facing of the cap."
>
> "In Figures 3 and 4, there is shown a suitable mechanism for applying the disc and adhesively uniting it to the cork insert at the time the strip is punched from the disc and assembled with the cap".

The Court of Appeals has inferred from this amendment to the specification that the claims presented at the same time were not intended to cover preheating. We submit that the inescapable inference in view of the broad lan-

guage inserted in the specification is that the patentee intended to emphasize the broad scope of his claim. Warth said, in effect:

> "I comprehend in my claim *any* way of producing heat for use at the time of assembly, whether by heating the punch or by heating the cork".

The heated punch is thus described merely as "a suitable mechanism" for adhering the spot at the time of assembly in accordance with the method thus broadly stated.

Hence, it is clear that the specification (1) states the method as broadly involving the application of heat and pressure to the spot at the time of assembly without limitation to the particular way they are applied, and (2) describes the heated punch merely as illustrative of "a suitable mechanism" for practicing this broad method.

2. The File of the Parent Patent Shows That No Amendments Were Made Which Justify Reading Into the Claims the "Heated Punch" Limitation.

The Court of Appeals referred (R. p. 1835) to certain amendments made during the prosecution of the Warth parent patent, and particularly the insertion of the drawing of the heated punch as well as the description of the punch operation.

We have already shown (*ante*, pp. 7, 8) that Warth's patent drawing, including the heated punch, is merely illustrative of what he identified as "a suitable mechanism" by which his method could be carried out. We have also shown (*ante*, p. 28) that the uncontradicted proof is that a preheated cork and a heated punch each accomplish the same final result. As the District Court (R. p. 1790) said:

> "The sole purpose of preheating the cork immediately in advance of the punch is to create heat, which will be available at the instant the spot is deposited, so that there will be provided the combined effect of heat and pressure."

Consequently, it was wholly immaterial whether Warth showed, as part of his illustrative mechanism, a heated punch or preheated cork. Both of them were known to him and described in his application as suitable procedures for applying heat to the spot at the instant of assembly. A showing of either will support a claim drawn in language sufficiently broad to cover both. The fact that he selected only one of them for purposes of illustration creates no inference that, thereby, he intended to limit his invention to that particular procedure.

It is true that, as the Court of Appeals said (R. p. 1835), when Warth filed his drawing, he also cancelled reference to preheating. But we have shown (*a*) (p. 7, *ante*) that, at the same time, he inserted the broader statement (R. p. 1272, quoted p. 8 *ante*) that his preferred method is broadly to utilize heat at the instant the spot is deposited, and (*b*) that such cancellation is customary procedure when, as here, a divisional case is filed (*ante*, p. 8).

Certainly, if any inference from this amendment to the specification is warranted, it is that Warth intended to emphasize, rather than to restrict, the breadth of his invention and to cover *any* way of applying heat to the spot at the instant of assembly.

As a further reason for its limitation of the parent patent claims to a heated punch, the Court of Appeals referred to the cancellation of certain broader claims (R. p. 1835) when the parent patent claims were inserted by amendment. But the Court of Appeals overlooked the fact that these cancelled claims were so broad as to be rejected by the Patent Office on prior art (R. pp. 1253, 1256). Furthermore, none of such cancelled claims had the scope petitioner is urging for the parent patent claims and the scope which the District Court gave them. Hence, such cancellation cannot be used to limit the present claims to a heated punch, because certainly no reference is made in them to a heated punch. This is not a case where a patentee inserted a limitation (heated punch) in his claims in order to induce their allowance by the Patent Office.

Finally, the law does not warrant the inclusion in the Warth claims of an element (heated punch) not expressly included therein. Yet that is precisely what the Court of Appeals did when it said that the Warth claims must be limited to mean "that the heat and pressure are applied *by a cutting punch*" (R. p. 1835).

This Court has held in a number of recent cases[23] that parts of the specification or of other claims which the patentee has not included in his claim cannot be read into that *claim by Court interpretation, even to save the claim.* Yet, in the case at bar, the Court of Appeals rewrote the Warth claims to include the heated punch, thus doing what this Court has said should not be done and, furthermore, as pointed out (*ante*, pp. 27, 28), doing what the Patent Office would not have permitted Warth himself to do since the heated punch was not part of the original disclosure. (*In re Dilg. ante*, p. 28.)

3. The Court of Appeals' Construction of the Claims Is Inconsistent With the Evident Intent of the Patentee and Deprives Him of Protection for His Actual Invention.

This Court has repeatedly held that, if a patent claim is susceptible of two constructions, that one should be adopted which will secure to the patentee his actual invention rather than one which is fatal to the grant.[24] By limiting the claims to a hot punch, the Court of Appeals has deprived petitioner of all protection for the Warth invention as it has always been employed by petitioner (R., pp. 94, 372-4).

The uncontradicted evidence is that petitioner has been using the preheating invention since 1926 (R. pp. 381, 383). Photographs of petitioner's 1926 machines (R. pp. 612A,

---

[23] *Altoona* v. *American Tri-Ergon*, 294 U. S. 477, 487; *Smith* v. *Snow*, 294 U. S. 1, 11; *Smith* v. *Hall*, 301 U. S. 216, 220.

[24] *Smith* v. *Snow*, 294 U. S. 1, 14; *Keystone* v. *Adams*, 151 U. S. 139, 144, 145.

612B), original 1926 drawings (Exhs. 47, 48, 49-Physical), and a typical spotting unit from such a machine (Exh. 46) are in evidence and were proved (R., pp. 374-379).

No one questions that preheating was part of Warth's original application disclosure, or that such disclosure was continuously before the Patent Office, either in the original or in the divisional applications, until the preheating claims were made.

But more than this, by undisputed evidence it has been shown that **the patentee Johnson (R. p. 575), from whom respondent acquired knowledge of the invention through machines purchased from Johnson, visited petitioner's factory in 1928 and observed petitioner's practicing of the preheating methods** (R. pp. 348-9; 358; 375). Johnson had been an inventor and builder of crown cap machinery for thirty-three years (R. p. 160) and had been working since 1927 to develop a method of applying spots to crowns (R. p. 167). Yet it was not until *after* he had visited petitioner's factory and studied the operation of petitioner's machines that he applied for the patent with which Warth was in interference and was able to supply respondent with machinery using the preheating method which is here charged to infringe.

Certainly it is clear that the original Warth application was filed to protect this method, as used, including preheating.

By restricting the claims of the parent patent to a heated punch, the Court of Appeals has so narrowed the patent that (1) it does not protect what Warth invented and disclosed and what petitioner has done since it began to use the Warth method and (2) it does not cover what respondent is doing as a result of information which its machinery supplier, Johnson, obtained by inspecting petitioner's operations.

Obviously, therefore, the interpretation of the parent patent adopted by the Court of Appeals is one which does not secure to the patentee his actual invention.

B. It is sufficient excuse that Warth reasonably believed that the parent patent claims cover the subject matter of the divisional patent claims and acted in accordance with that belief.

Since, in the case at bar, the Court of Appeals agreed that Warth's delay would be excusable if the Court had construed the parent patent claims to be of such scope that they would cover preheating, it is submitted that it should have, in any event, excused the delay because the parent patent clams are, at least *seemingly*, broad enough on their face to cover preheating and that Warth believed in and relied on such seeming scope.

This should be the rule since one's diligence at a particular time should be measured in the light of the circumstances (parent patent claims' scope) as then reasonably understood by him, and not as later and unexpectedly determined by judicial inquiry.

In each of the cases cited (*ante*, p. 25), delay in filing application and presenting claims was held excused because of the belief, even though mistaken, that the subject-matter had been covered by earlier applications or patents.

The foregoing discussion (*ante*, pp. 27-32) of the language of the parent patent claims and of the patent record shows that the claims of the parent patent, at least on their face, are reasonably susceptible of an interpretation which will cover preheating.

Moreover the record establishes that Warth actually believed the claims to be of such breadth and so relied upon them. His conduct is consistent with no other conclusion.

As soon as petitioner learned that Johnson had obtained his patent and was making for others machines for practicing the preheating method (R. pp. 522, 523) he was notified of infringement of the parent patent. Petitioner's notice of infringement to respondent (R. p. 2185) of infringement of the parent patent (R. p. 565), when (R. p. 521) petitioner learned of respondent's activities, is further evidence that

petitioner, *in fact*, relied upon the claims of the parent patent as covering preheating.

The conclusion of the District Court that the parent patent covered preheating is evidence that petitioner's reliance on the broad scope of the claims of that patent was not unreasonable. This is also shown by Johnson's admission of concern with respect to infringement (R. pp. 164, 925) and his acceptance of a license under the patent.

Summary as to Excuse for Delay.

If, under the circumstances of this case, an excuse for Warth's delay in asserting specific preheating claims is required, then the facts, which we have just explained in detail, adequately provide such excuse.

Warth had the invention in use as early as 1926. His original specification admittedly disclosed it and his original claims admittedly covered it. He obtained, in the parent patent, claims which do cover preheating or, at least, are reasonably susceptible of such a construction.

Warth relied upon the claims of the parent patent as affording a monopoly sufficiently broad to exclude others from using preheating, as shown by notice to Johnson and respondent of infringement of the parent patent as soon as their use of preheating became known.

Moreover, there was no delay by Warth in asserting his prior inventorship of preheating after Johnson's patent with specific preheating claims came to Warth's attention. As pointed out *ante*, p. 9, if, through oversight, the Patent Office had not failed to declare an interference between the Johnson application and Warth's original application, the question of priority would have been determined in the manner provided by the Statute and the Patent Office Rules while Warth's *original* application was pending. Warth would, by such interference, have had actual notice of the necessity for presenting specific preheating claims since such claims then stood allowed in the Johnson application (R. pp. 712, 717).

In *Chapman* v. *Beede,* 296 Fed. 956, 959, (App. D. C.), where there had been a similar oversight on the part of the Patent Office in declaring an interference, the Court recognized that the applicant was entitled to the benefit of the equitable maxim that the Courts view as done what ought to have been done and excused a delay of more than two years because the inventor had previously claimed substantially the same invention. Warth, like the inventor in the *Chapman-Beede Case,* in presenting the specific claims was simply covering what he had originally disclosed and claimed broadly, without any intent to expand his disclosure to cover later methods which had come to his attention. By making such specific claims, when the Johnson patent came to his attention, Warth immediately obtained an interference with the Johnson patent so that the Patent Office would have opportunity to correct its mistake.

Clearly Warth should not be penalized for delay directly traceable to this Patent Office oversight.

This Court, in *Chapman* v. *Wintroath supra,* appreciated the inequity of penalizing an inventor whose delay in presenting claims is attributable to a Patent Office failure to declare an interference with an inadvertently issued patent. The Court said (pp. 138, 139):

> "But when a conflict between inventions disclosed in applications *escapes the attention of the Patent Office Examiners,* Rev. Stats., Sec. 4904, and a patent is issued, with claims conflicting with the disclosures of a pending application, the applicant receives only such notice of the conflict as he is presumed to derive from the publication of the patent. In the one case the notice is actual and specific, in the other it is indefinite and constructive only. When the great number of patents constantly being issued is considered, many of them of a voluminous and complicated character, such as we have in this case, with many and variously worded claims, such an implied notice must necessarily be precarious and indefinite to a degree which may well have been thought to be *a sufficient justification for allowing the longer two-year period to inventors who*

must, at their peril, derive from such notice their knowledge of any conflict with their applications.''

While Warth might have made claims specific to preheating in his original application, he should not be charged with lack of diligence in failing to do so until he had notice, as by issuance of the Johnson patent, of any reason to present specific preheating claims.

We submit that, in view of the foregoing, the Court of Appeals should have excused Warth's delay and held the divisional patent valid.

POINT V.

The Grant of the Divisional Patent is Not Inconsistent with a Broad Interpretation of the Parent Patent Claims.

The reason assigned by the Court of Appeals for adopting a limited construction of the parent patent claims was (R. p. 1836):

> ''To read them to mean a cold punch which positions the spot on a preheated cork would be inconsistent with the fact that the preheating specification was deliberately divided out and later claimed in Warth's 'preheating patent' hereafter to be discussed''.

The above-quoted statement apparently overlooks the fact that a customary procedure when protecting by a separate divisional application, a divisible part of what is disclosed in an original parent application, is to cancel the disclosure of that part from the parent application when it is embodied in the separate divisional application. As the District Court said (R. p. 1800), the Warth divisional patent subject-matter

> ''was specifically reserved by continuous inclusion in the divisional application and later in the second division. This has been approved and is the usual practice. *Writer* v. *Kiwad*, 63 Fed. (2d) 259.''

The Court of Appeals obviously overlooked the fact that the two patents have a logical and valid relationship when

the claims of the parent patent are broadly construed. In other words, the parent patent claims cover broadly *any* way of applying heat simultaneously with pressure to the spot at the instant the spot is deposited upon the cork. The hot punch is illustrated as one suitable means for doing this. When the parent patent expires, the public will be free to use any method involving the use of heat simultaneously with pressure at the instant of assembly *except* the specific way (preheating) claimed in the divisional patent. The divisional patent, therefore, does not extend the parent patent monopoly, as respondent has suggested.

This relationship between the two Warth patents is the one which usually exists between broad parent and specific divisional patents. Therefore, the District Court (R. p. 1804) correctly said:

> "None of the claims of the divisional patent is readable upon the disclosure of the reissue, and therefore when the Reissue Patent expires, the public will be free to practice the method without infringing the divisional patent, that is, the public may employ any method of obtaining the heat at the instant of assembly except the specific 'heating the pads in the caps' covered in the later patent.
>
> "The Reissue Patent is the generic and the divisional the specific patent, and therefore the reissue does not anticipate the divisional patent."

POINT VI.

The Court of Appeals Should Have Found that Respondent Infringes the Claims of the Warth Parent Patent.

The Court of Appeals did not suggest that the parent patent claims would be anticipated by the method of petitioner's slide machine (Appendix, pp. 41, 42) or by other prior art if the claims were construed to cover preheating. As we have already shown, it narrowly construed the claims only because of (*a*) certain inferences drawn from proceedings in the prosecution of the parent patent, and (*b*) a misreading of the language of the parent patent claims.

We have shown that there is nothing in the patent file which precludes the interpretation for which we contend and that the language of the claims applies clearly to a method in which the heat is obtained *either* from the punch or from a heated cork.

Referring to the claims, the Court of Appeals said (R. p. 1836):

> "To read the claims of the reissue patent to mean a cold punch to cut the spot and a hot plunger applied later to fasten it to the cork disc would make them invalid under the old 'slide machine'."

We admit that the claims do not cover a cold punch for cutting the spot *unless in the same operation heat and pressure are simultaneously applied to the spot.* Petitioner has never asserted, nor is there anything in the record to suggest, that the claims read upon the use of a cold punch followed by the application of heat by a hot plunger *later or at another station.* Consequently, this alternative procedure proposed by the Court has no bearing on any issue in the case.

But the important point is that the Court did not find that the claims would be anticipated *if construed to cover the simultaneous use of heat and pressure at the instant of assembly, whether the heat comes from the punch or from the cork.* Therefore, the Court of Appeals did not reverse the holding of the District Court that the claims, if construed as they read, would be valid over the prior art.

We submit that the construction of the claims adopted by the District Court was correct, since it is the only interpretation which is consistent with the claim language and with the evident intent of the patentee as shown by his conduct in the prosecution of his parent patent (1,788,260) and after the grant of the patent. Moreover, it is the only interpretation which secures to the patentee protection for his real invention.

The Court of Appeals found (R. p. 1837) that respondent infringes the claims of the divisional patent and since those claims are merely for a specie (preheating) of the invention claimed in the parent patent, this is the equivalent of a finding of infringement of the parent patent, if the claims thereof be construed as petitioner contends. Respondent uses the spotting method of the Johnson patent (R. p. 575). As the Court of Appeals said (R. p. 1835, footnote), respondent uses a cutting punch which, by radiation from adjacent "preheater" and "post heater" plungers, has a temperature of approximately 140° F. Respondent *also* heats the cork. Thus, respondent applies the heat to the spot at the instant it is assembled, partly from the punch and partly from the cork. The fact that respondent, in addition to using a heated punch, also employs a heated cork to render the adhesive tacky, certainly does not avoid a patent which initially described the use of the heated cork and thereafter illustrated the heated punch as *another* example. Respondent simply chose to use *both* the punch and the cork as sources of heat, instead of a single source. Although the heat (140°) in respondent's punch alone might not suffice for efficient operation, respondent certainly makes use of a heated punch, and to this extent employs the invention of the Warth parent patent claims, even as limited by the Court of Appeals.

The claims should be accepted as they read and are valid. The District Court so found and clearly pointed out (R. pp. 1785-87; 1789-90) how the claims, construed as petitioner urges, distinguish from the prior patent art, as well as petitioner's old "slide" machine method.

CONCLUSION.

It is submitted that the decree of the Court of Appeals should be reversed and that this Court should hold:

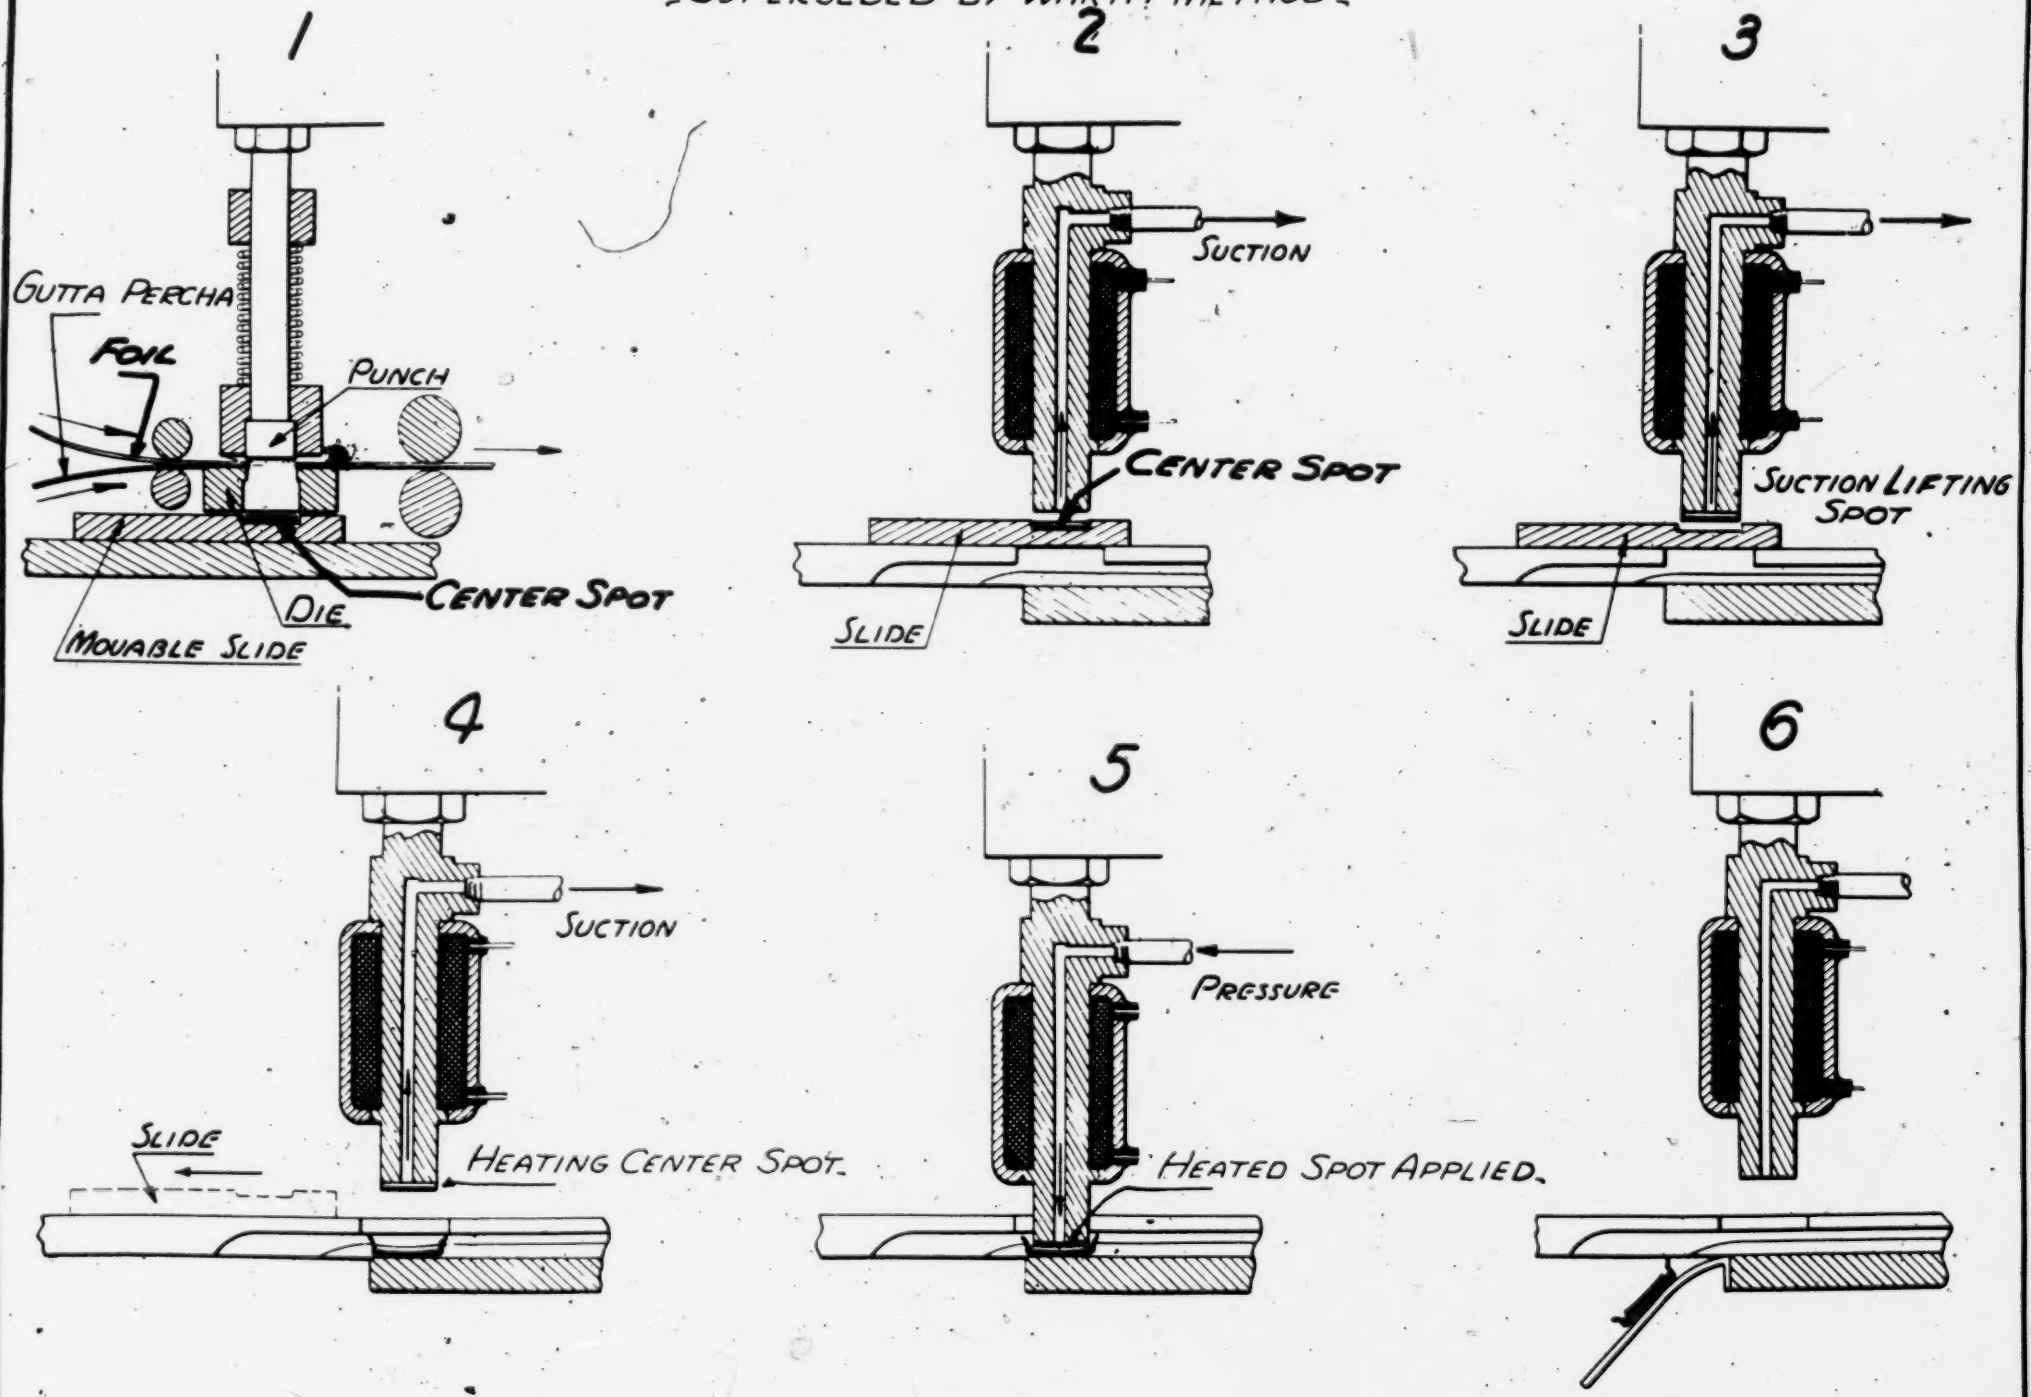
1. That the doctrine of *Webster* v. *Splitdorf* applies only where there have been intervening adverse rights more than two years prior to the filing of a divisional application

and, in the absence of such intervening rights, no excuse for delay in presenting the claims in a divisional application is required.

2. That, even if an excuse be required for Warth's delay in presenting his divisional patent claims, the record shows an adequate excuse in that the parent patent claims are, in fact, or at least seemingly, of sufficient breadth to dominate the "preheating" method of the divisional patent and Warth reasonably relied upon the claims as being of such scope.

3. That the claims of the Warth divisional patent are valid and infringed.

4. That the claims of the Warth parent reissue patent are valid and infringed.



Respectfully,

THOMAS G. HAIGHT,
GEORGE F. SCULL,
JOHN J. DARBY,
GEORGE W. PORTER:
Counsel for Plaintiff-Petitioner.

PETITIONER'S "SLIDE" METHOD
SUPERSEDED BY WARTH METHOD

BLANK

PAGE

APPENDIX.

Petitioner's Old "Slide" Machine.

The operation of this machine, as disclosed by contemporaneous description and photographs (R. pp. 613, 614A, B), is illustrated by the drawings opposite this page. Separate strips of tin foil and gutta percha tissue were fed, one over the other, beneath a cutting punch which cut out a disc from each strip and deposited them in a cavity in a movable slide. Then the slide moved horizontally, carrying the cut-out discs beneath an electrically heated suction plunger which, by its suction, lifted the two discs from the slide cavity and held and heated them while a crown shell containing a cork cushion was being moved beneath the plunger and the slide was being withdrawn. Then the plunger descended with the already-heated spot and pressed it against the crown, the suction being changed to pneumatic pressure, which blew "the spot from its position * * * onto the crown" (R. p. 613). The crown was then ejected from the machine.

The Warth Method and Slide Machine Differ Essentially.

Claim 3 of the Reissue patent quoted in the footnote (p. 4, *ante*) specifies the essential differences between the Warth method and the method involved in petitioner's old slide machine, over which, as the District Court said, "the [Warth] method has great advantages" (R. p. 1785). The District Court (R. p. 1790) found that:

> "The combination of steps defined in the Warth methods of the patents in suit are not found in the plaintiff's first or slide machine, and it does not anticipate".

The Court of Appeals did not disagree with this, but construed the claims of the parent patent narrowly because of certain inferences which it drew from occurrences during the prosecution of the application for the Warth parent patent.

The method as defined in the claim covers the combination of all the steps and specifies the stage at which the heat is applied *to the spot*. The claimed method involves the following:

> *First*, a strip coated with thermoplastic adhesive is positioned beneath a punch and over a crown. (The slide machine used *separate* strips of tinfoil and gutta percha).
>
> *Second*, the punching operation is utilized to deposit the spot upon the crown in central position. (The punch in the slide machine deposited the gutta percha and foil discs in a slide).
>
> *Third*, heat and pressure are utilized simultaneously upon or at the instant of assembly, to adhere the spot. (In the slide machine the discs were lifted from the slide and heated *before* deposit on the crown).
>
> *Fourth*, the crown is cooled under pressure (claim 3). (There was no pressure on the crown during cooling in the slide machine).

While each of the steps is vital, as petitioner's witness puts it (R. p. 67):

> "This last [Third, *supra*] step of applying both heat and pressure instantly with assembling serves the useful purpose of positioning the center spot centrally in the cap and enables it to stay put until further operations can be performed. This must be done instantly. Where you are running a machine at 500 per minute there is no time to wait, and one must be sure that the spot is centrally positioned.
>
> "The use of heat and pressure instantly with deposit of the spot might be considered the keynote of the entire operation. However, the three steps are like, I might say, the three steps of a tripod. Without any one of these steps the method will not function".

In the slide machine, none of the steps above described was performed. The spot was not punched over the crown. The punching operation was not used to deposit the spot on the crown. The heat was applied to the spot *before* it was assembled with a crown, *i. e.*, by a hot plunger which

lifted it from the slide and held the spot for heating while the slide was withdrawn and while a crown was positioned beneath the plunger. Finally, in the slide machine there was no cooling of the spot under pressure. As a result, the speed of production was very slow and defective crowns were frequent (R. p. 370).

U. S. C., Title 35; Sec. 52 (R. S. Sec. 4904).

"Whenever an application is made for a patent which, in the opinion of the commissioner, would interfere with any pending application, or with any unexpired patent, he shall give notice thereof to the applicants, or applicant and patentee, as the case may be, and shall direct the primary examiner to proceed to determine the question of priority of invention. And the commissioner may issue a patent to the party who is adjudged the prior inventor, unless the adverse party appeals from the decision of the primary examiner, within such time, not less than twenty days, as the commissioner shall prescribe."

Rule 96—Rules of Practice in the United States Patent Office.

"96. Whenever the claims of two or more applications differ in phraseology, but relate to substantially the same patentable subject matter, the examiner shall suggest to the parties such claims as are necessary to cover the common invention in substantially the same language. The examiner shall send copies of the letter suggesting claims to the applicant and to the assignee, as well as to the attorney of record in each case. The parties to whom the claims are suggested will be required to make those claims within a specified time in order that an interference may be declared. Upon the failure of any applicant to make any claim suggested within the time specified, such failure or

refusal shall be taken without further action as a disclaimer of the invention covered by that claim unless the time be extended upon a proper showing. After judgment of priority the application of any party may be held for revision and restriction, subject to interference with other applications.

Whenever it shall be found that two or more parties whose interests are in conflict are represented by the same attorney, the examiner shall notify each of said principal parties and also the attorney of this fact."

U. S. C., Title 35, Sec. 31 (R. S. Sec. 4886).

"Any person who has invented or discovered any new and useful art, machine, manufacture, or composition of matter, or any new and useful improvements thereof, or who has invented or discovered and asexually reproduced any distinct and new variety of plant, other than a tuber-propagated plant, not known or used by others in this country, before his invention or discovery thereof, and not patented or described in any printed publication in this or any foreign country, before his invention or discovery thereof or more than two years prior to his application, and not in public use or on sale in this country for more than two years prior to his application, unless the same is proved to have been abandoned, may, upon payment of the fees required by law, and other due proceeding had, obtained a patent therefor."

U. S. C., Title 35, Sec. 33 (R. S. Sec. 4888).

"Before any inventor or discoverer shall receive a patent for his invention or discovery, he shall make application therefor, in writing, to the Commissioner of Patents, and shall file in the Patent Office a written description of the same, and of the manner and process of making, constructing, compounding and using it, in such full, clear, concise,

and exact terms as to enable any person skilled in the art or science to which it appertains, or with which it is most nearly connected, to make, construct, compound, and use the same; and in case of a machine, he shall explain the principle thereof, and the best mode in which he has contemplated applying that principle, so as to distinguish it from other inventions; and he shall particularly point out and distinctly claim the part, improvement, or combination which he claims as his invention or discovery. The specification and claim shall be signed by the inventor. No plant patent shall be declared invalid on the ground of noncompliance with this section if the description is made as complete as is reasonably possible."

Claim 35 (R., p. 925) of the Johnson Application Which Was Not Suggested by the Patent Office to Warth for Interference Purposes as it Should Have Been Under the Statute and Rule (Appendix, p. 43 ante.)

"35. The method of assembling linings for sealing pads in receptacle closure caps, consisting in providing caps with sealing pads assembled therein and a web of lining material having an adhesive surface non-viscous at normal temperature, severing linings from the web of lining material and assembling the linings as they are severed from the web in the caps with the adhesive surface in contact with the pads, then placing the linings in the caps under heat and pressure to render the adhesive viscous and effect an intimate contact between the linings and pads."

Utah Radio Corp. Products Co. v. Boudette (C. C. A. 1st), 78 F. (2d) 793.

The Court, stating the facts of the Webster case, pointed out that the subject-matter of the divisional claims had been disclosed in a Podlesaks patent issued over five years before the claims were first presented and had been in public use by others than the patentee for over five years.

The court said (at p. 799) after referring to the Webster case, that claims may "reasonably" be presented at any time within two years after the adverse public use:

> "*In that* [*Webster*] *case the court applied by way of analogy the statutory two-year period of prior publication and public use* * * *.
>
> "There the subject-matter of claims 7 and 8, though not claimed in the Podlesaks patent, was disclosed by it, and, consequently, on the issuance of that patent in 1913, was published and given to the public.
>
> "In the case now before us, the subject-matter of claims 1, 2, and 5 here in issue was known and *in public use* through the sale of RCA loudspeaker 104 *in November, 1925,* some four years before claims 1, 2 and 5 were asked for, whereas they reasonably *could have been inserted* in the original application of April, 1926, or *at any time thereafter up to two years from November, 1925,* but were not until October 17, 1929, when the divisional application was made."

Wagenhorst v. Hydraulic Steel (C. C. A. 6th) 27 F. (2d) 27, 29.

The Court (Denison, J.,) after reciting the facts of *Webster* v. *Splitdorf,* said with reference to that case:

> "From the recitals and reasoning of the [Webster case] opinion, we are unable to see that the fact that the amendment of 1918 was presented in a divisional application, instead of an original application, was of any importance to the result reached. The long delay which elapsed between the original and the divisional was important, *not because it was the interval between these two applications, but because it extended so long after the 1913 public disclosure.* If the original application of 1910 had not matured into a patent in 1916, but had continued pending, and the amendment in 1918 had been offered in that original application, and the facts had been otherwise the same, we see nothing in the opinion, and no reason occurs to us, which would indicate a different result. In other words, claims 7 and

8 were invalid *because*, in an effort to broaden any previous statements of the invention, *they were first presented by an amendment offered five years after their subject-matter had been disclosed to the public by the Podlesaks patent;* and such an effort to broaden the claim of invention was, by analogy to the reissue rule, barred by laches, estoppel, and intervening rights. In the present case the divisional application was filed promptly after the intervening device appeared, and the Webster Case does not apply."

Wirebounds Patents Co. et al. v. Saranac (C. C. A. 6th), 37 F. (2d) 830, 840, 841.

The District Court had held the patent in suit invalid under the ruling in the Webster case. The Court of Appeals (Denison, J.,) discussing the *Webster* case reversed the District Court and said:

"This [District Court decision] was before we had by our Wagenhorst Case, * * * adopted our interpretation of the Splitdorf decision." * * *

"This case is plainly not within the Splitdorf rule, as we understand it, either by parallelism or by strict analogy. Defendant points out, as a general analogy, that the machine and method had been in public use by the applicants, who became the patentees, and under licenses from them, all for more than two years before the divisional application was filed. This is true. When it is remembered that the divisional application is normally entitled to the benefit of the original filing date, it is not easy to see how public use under license from the applicants can amount to that laches under which adverse rights may arise; *or how the Splitdorf rule can apply unless the delay is after the public appearance of an adverse claimant, or, perhaps, one who may be an adverse claimant;* but we find it unnecessary to decide that question".

Wirebounds Co. v. Saranac (C. C. A. 6th), 65 F. (2d) 904, 905, 906.

"In view of the circumstances above mentioned, the cases of Webster Electric Co. v. Splitdorf Electric Co., 264 U. S. 463, 44 S. Ct. 342, 68 L. Ed. 792, and Chapman v. Wintroath, 252 U. S. 126, 40 S. Ct. 234, 64 L. Ed. 491, while dealing with one phase of laches and delay, are not precisely in point, for in them the making of amendments, the copying of claims for interference purposes, or the filing of divisional applications, was necessitated by the issue of a patent to another inventor, which patent wholly or partially covered the same ground as the pending application, and the sole purpose of the then applicant was to obtain a patent in terms broad enough to cover that already issued. These two cases held that, in analogy to the existing limitation upon a right to reissue, unexplained delay and neglect upon the part of an applicant, for more than two years, in bringing forward claims broader than those originally sought, that is, *a delay of more than two years after the issue of the other patent,* constituted laches by which the applicant lost whatever rights he might otherwise have had. Both cases had reference to interfering patents in respect of the same subject-matter. This we do not find in the present case, but the two cited cases are interesting as showing one set of circumstances in which rights which might otherwise have existed may be forfeited by laches."

Hopfelt v. Read, 190? Commissioner's Decisions, 319, 320, 321.

"The disclosure in the original application is identical with the disclosure in the later application involved in this interference. The interference is the same as though the earlier application had been included in place of the later one. The reason that the earlier application was not included was due to the fact that under the practice of the Office the claims could could not be made therein and it was necessary to file a divisional application. * * *

"This is so when two applications are pending contemporaneously and the first is not abandoned, whether the claims are presented in the original application itself or in a later application filed as a division or a continuation of the original application, as in the second case the later application dates back to the earlier one. *It is only necessary that the description in both applications shall be sufficient to support the claims. The fact that the Office practice may prohibit the prosecution and allowance of the claims in an earlier application does not prevent an applicant from availing himself of the earlier date of filing as his date of constructive reduction to practice* when he files a later application containing the same description and the claims based upon the same."

I. Respondent's Argument (Br. pp. 8-13) that the Invention of the Divisional Patent was Abandoned 2

A. Abandonment Was Not Pleaded by Respondent, as Required by the Statute, and Therefore is Not an Issue in this Case.... 3

B. There Was No Intent to Abandon the Divisional Patent Invention 4

1.—The Cancellation of Claims in the Prosecution of the Original Patent 4

2.—The Cancellation of the Specific Reference to Preheating in the Parent Patent Specification 7

3.—The Issuance of the Parent Patent Without a Description of Preheating and Before the Divisional Patent Claims Were Presented, Does Not Warrant an Inference of Intent to Abandon Preheating 8

C. To Negative Abandonment, the Invention of a Divisional Patent Need Not Have Been Claimed in its Parent Application.. 9

II. Respondent's Argument (Br. pp. 14-22) that the Divisional Patent is Not a Proper Division of the Warth 1930 Application and that the Latter is Not a Proper Division of the Original Warth Application 13

A. Disclosure of an Invention in an Application, even Without a Claim therefore, is Sufficient Basis for a Divisional Application for that Invention 15

B. Warth's Divisional Applications Complied With the Patent Office Rules to the Satisfaction of the Patent Office 17

Page

III. Respondent's Argument (Br. 22-24) that the Johnson Patent Properly Issued Without an Interference With the Original Warth Application 20

IV. Respondent's Argument (Br. pp. 24-25) that the Cancelled Preheating Description in the File of the Original Warth Patent Was a "Publication" 21

The Patent Office File Wrapper is Not a "Printed Publication" within the Meaning of the Statute (R. S. 4886) 22

V. Respondent's Argument (Br. pp. 26-32) that There Were Adverse Intervening Rights Against the Divisional Patent 24

The Record Supports the District Court's Finding that There is No Proof of Adverse Intervening Rights 26

1.—Alleged Intervening Rights Arising from Respondent's Activities 26

2.—Alleged Intervening Rights Arising from Johnson's Activities 30

VI. Respondent's Argument (Br. pp. 30-32) that Petitioner Knew in 1930 that Respondent Was Making and Selling Center Spot Caps and Should Have then Ascertained the Method Respondent Was Using 31

VII. Respondent's Argument (Br. pp. 33-35) that Petitioner's Laches Began With Johnson's Building of Machines for Petitioner in 1929 32

VIII. Respondent's Argument (Br. pp. 36-39) that Its Purchase of Machines from Johnson Before the Issue of His Patent Gives Respondent a License Under the Warth Divisional Patent..... 33

A. The Warth-Johnson Interference 33

B. Respondent's Claim to a License 35

IX. Respondent's Argument (Br. pp. 44-47) Denying Infringement of the Reissue Patent 37

Page

X. Respondent's Argument (Br. pp. 47-53) that the Warth Patents in Suit Involve no Invention Over the Prior Art 39

Conclusion 40

IN THE

Supreme Court of the United States

OCTOBER TERM 1937

No. 72

CROWN CORK & SEAL COMPANY, INC., *Plaintiff-Petitioner,*

v.

FERDINAND GUTMANN & COMPANY, *Defendant-Respondent.*

REPLY BRIEF FOR PLAINTIFF-PETITIONER.

We reply herein to respondent's arguments in the order they are presented in its brief.

Respondent raises numerous defenses unrelated to the questions presented in the petition and on which the writ was granted. Each of these unrelated defenses was expressly rejected by the District Court and not discussed in the opinion of the Court of Appeals, although argued before that Court.

Although we think this Court, in view of the decisions below, will not examine these defenses, we answer them all herein, except the defense of non-invention over the prior art which we answer in a separate brief filed herewith.

I. Respondent's Argument (Br. pp. 8-13) that the Invention of the Divisional Patent Was Abandoned.

Respondent now contends that the preheating invention was abandoned and refers (Br. p. 9) to a discussion of this case by the Court of Appeals for the Second Circuit in its later decision in *Western Electric* v. *General Talking Pictures Corp.*, 91 F. (2d) 922, in which later case the Court[1] made the remark that Warth abandoned his invention.

Regardless of what respondent now asserts the Court of Appeals *intended* to hold in its decision in the case at bar, a reading of the decision below shows that the Court actually held the divisional patent invalid, not on a finding of abandonment, but only because of laches and unexcused delay in presenting claims. There is no reference whatsoever to *abandonment* in the Court of Appeals' decision. If that decision had been based upon a finding of abandonment, there would, of course, have been no point in the Court's statement that no "excuse appears here for delay" nor in its repeated reference to "apathy and unexcused delay" in bringing forward the divisional claims.

The distinction between laches and abandonment has been repeatedly recognized. For example, in *Utah Radio Products Co.* v. *Boudette* (C. C. A. 1st) 78 F. (2d) 793, 799, in discussing the applicability of *Webster* v. *Splitdorf*, 264 U. S. 463, the Court said:

> "This is a case of laches, not of abandonment. To prove abandonment it is necessary to show an intention on the part of the inventor to abandon or give the subject-matter to the public; but where laches—unreasonable delay—is the issue, the intent is unimportant, and especially so where public rights have attached pending the delay."

Moreover, in the case at bar, the Court of Appeals based its finding upon the decision of this Court in the *Webster*

[1] By Manton, J. who dissented in the case at bar.

case, *supra,* and, in that case, this Court applied the doctrine of laches as distinguished from abandonment.

A. Abandonment was not pleaded by respondent, as required by the Statute, and therefore is not an issue in this case.

Under the Statute,[1] which we quote in the Appendix, (p. 41), abandonment must be specifically pleaded or noticed as a defense before trial. Respondent did not plead it (I, 24-31) or give the required notice. Hence, the question of abandonment was not before the Court of Appeals. Nor was it raised by assignment of error, notwithstanding the fact that the District Court found as a fact (III, 1800) that the invention had not been abandoned.

The courts have uniformly construed the Statute to mean that there must be pleading or notice of the defenses specified therein, which defenses specifically include that of abandonment. Not only is the Statute mandatory, but the courts have recognized that it is unfair to plaintiff to have such an unpleaded defense considered.

> "Moreover, the defense of abandonment was not pleaded, and the appellant had no opportunity to meet it by evidence". *Mast, Foos & Co.* v. *Dempster,* (C. C. A. 8th) 82 Fed. 327, 331.

B. There was no intent to abandon the divisional patent invention.

Respondent refers (Br. p. 10 *et seq.*) to certain proceedings in the prosecution of the original patent as "*indications*" of intent to abandon the subject-matter of the divisional patent.

It is settled law[1] that the burden of proving abandonment rests heavily upon him who alleges it and that abandonment is a question of intent, *not to be presumed.* In *Rifle Co.* v. *Whitney,*[1] this Court said that, if abandonment is not proved "by express declarations of intention to abandon", **it must be proved "by conduct inconsistent with any other conclusion".**[2]

We will now show that Warth's conduct in prosecuting his original application not only creates no presumption of abandonment, but that, on the contrary, any possible inference of abandonment is clearly rebutted by his affirmative acts.

1.—The Cancellation of Claims in the Prosecution of the Original Patent.

Respondent contends (Br. p. 10) that, since Warth originally filed, but later cancelled, certain claims (III, 1247, 1248) sufficiently broad to cover the use of *either* a preheated cork or a heated punch for applying heat to the spot, and accepted other claims which, we submit, the Court of Appeals unwarrantedly held to be limited to a heated punch, he intentionally abandoned any right to make claims covering *specifically* the use of a preheated cork as he later did in his divisional patent.

Respondent's argument completely overlooks the fact that these cancelled claims were so broad as to be properly

[2] Emphases ours throughout unless otherwise stated.

rejected by the Patent Office on prior art (III, 1253-1256). Consequently, when Warth cancelled them, he was not abandoning any part of *his invention.* Nor does such cancellation afford a basis for giving the claims which he did accept a meaning narrower than their language compels, as respondent, in effect, argues should be done. Moreover, none of the cancelled claims was specifically directed to the application of heat by means of a preheated cork.

When, therefore, petitioner now asserts that the claims which Warth did accept in the parent patent cover the application of heat by means of a preheated cork, it is not asking for any interpretation of the patent claims which will include anything which was surrendered in order to obtain the patent. Nor did Warth, when he presented his *divisional* patent claims, ask for protection for anything surrendered by claim cancellation in the prosecution of the application for the parent patent.

Hence, the cancellation of the rejected claims in the parent application creates no inference of abandonment of preheating and does not warrant the application of the estoppel rule. The Courts have repeatedly held[1] that estoppel arises from claim cancellation only where an interpretation is urged for the claims of the patent which would make them the same in scope as the cancelled claims.

But that is not the situation here. No single claim cancelled during the prosecution of the original patent specified, as do the claims of both Warth patents (*a*) that the spot is punched over the cork, or (*b*) that the punching operation deposits the spot on the cork, or (*c*) that, upon or at the instant of assembly, heat and pressure are applied simultaneously. To all of these steps, the parent patent claims are admittedly restricted and petitioner is not asking a broader interpretation. Moreover the claims of the divisional patent are *additionally* limited to applying the heat

[1] *National Hollow B. B. Co.* v. *Interchangeable,* (C. C. A. 8th) 106 Fed. 693, 714; *Wayne Co.* v. *Benbow,* (C. C. A. 8th) 168 Fed. 271, 279; *Scaife & Sons* v. *Falls City* (C. C. A. 6th) 209 Fed. 210, 216-217; *National Tube* v. *Mark* (C. C. A. 6th) 216 Fed. 507, 522.

to the spot by preheating the cork, and certainly no claims to this were ever cancelled.

To supports its argument for abandonment of preheating, respondent cites (Br. p. 13) a number of cases in which claims were refused an applicant on the ground of *res adjudicata,* corresponding claims having been rejected and abandoned in earlier applications. These decisions are not in point, since, as we have shown, the claims of Warth's divisional patent do not correspond to any claims which were rejected or cancelled in the parent application. Moreover, even if they did, the Patent Office had a right to waive the question, as this Court specifically held in *Overland* v. *Packard,* 274 U. S. 417, 421:

> "As the Patent Office by granting the patent must be held to have waived any objection to the application on the ground that the claim allowed had been rejected before by that Office, there is no reason why the appellees below should not be allowed to avail themselves of the waiver."

No abandonment of preheating is to be inferred from the acceptance of the parent patent claims, because, as we show in our main brief (pp. 27-29, 33-34), (*a*) the Court of Appeals unwarrantedly read into those claims the "heated punch" limitation, and (*b*) Warth reasonably believed that the parent patent claims did cover preheating, which belief was in accord with the findings of the District Court.

Whether Warth was mistaken or not, it is clear that his acceptance of the claims is not "conduct inconsistent with any other conclusion" than abandonment of preheating (*Rifle Co.* v. *Whitney,* p. 4 *ante* footnote), particularly since the preheating invention had been reserved by disclosure in the previously-filed 1930 divisional application.

2.—The Cancellation of the Specific Reference to Preheating in the Parent Patent Specification.

Respondent refers to the cancellation of the "preheating" description as "indicating" an intent to abandon any right to protect this invention and the Court of Appeals also referred to this amendment. We have shown (Main Br., p. 7) that, when Warth cancelled this specific description, he inserted the *broader* statement (III, 1272, l. 11 *et seq.*) which reads:

> "The preferred method of applying the material to the cap is to utilize, at the time of assembly, both heat and pressure to unite the spot to the cork or cushion material * * *.
>
> "In Figures 3 and 4, there is shown a suitable mechanism for applying the disc and adhesively uniting it to the cork insert at the time the strip is punched * * *".

We have also shown that Warth had previously included the preheating disclosure in his copending 1930 divisional application (III, 1668), the specification of which was identical with the original application and thus followed the practice established by the Patent Office and the Courts for preserving an inventor's right to every part of his application disclosure. See the decisions cited page 10, *infra*. Although the single claim of this 1930 divisional application (III, 1675) was directed to the strip material, the application specification states at the outset (III, 1671):

> "This invention relates to a *method* of producing closures of the type in which a sealing disc has a facing.
>
> This application is a division of my co-pending application Serial No. 159,743, filed January 7, 1927".

The copending application referred to in the above quotation was the original Warth application, and, in accordance with Warth's statement, the Patent Office duly endorsed the file (II, 669), thus formally recognizing, in ac-

cordance with the established practice, that this second application was entitled to the filing date of the original application.

Since Warth, when cancelling preheating from his original specification, *broadened*, and did not narrow, his statement of the manner in which heat is applied simultaneously with pressure, the inescapable inference is that he intended to emphasize the breadth of his invention and not to narrow it.

3.—The Issuance of the Parent Patent Without a Description of Preheating and Before the Divisional Patent Claims Were Presented, Does Not Warrant an Inference of Intent to Abandon Preheating.

Respondent cites (Br. p. 12) *McClain* v. *Ortmayer*, 141 U. S. 423, and *Deering* v. *Winona Harvester Works*, 155 U. S. 286, in support of its contention that the issuance of the parent patent, before specific preheating *claims* were presented, "indicates" an intent to abandon. In each of these cases, the subject-matter which was held dedicated to the public was not reserved in any copending application and was *described in the issued patent*. But the Warth parent *patent* did not describe preheating.

In the case at bar, Warth did exactly what this Court stated in *Overland* v. *Packard*, (274 U. S. 417, 420) would not warrant a holding of abandonment. In the *Overland* case, Cowles, in 1899, had filed an application disclosing more than one invention. The description of the invention in controversy was later cancelled from the application and the application went to patent on July 13, 1900. On September 6, 1901, over thirteen months after that patent issued, Cowles filed another application disclosing and claiming the invention cancelled from the earlier application and which he was charged with having abandoned. The invention was finally patented in a division of the 1901 applica-

tion, the division having been filed in 1912. This Court said (at 420):

> "We do not find in the statement of facts any circumstances which can be held to be an abandonment by Cowles of his claim for which he subsequently secured his patent."

Similarly, in *Folberth Auto Specialty Co.* v. *Mayo,* 292 F. 883, 894 (D. C. Ill.) the Court held that a disclosure in a patent issued more than two years patent before claims were presented in a divisional application does not constitute abandonment or dedication to the public, *since the subject-matter was disclosed in an intervening application copending with the earlier issued patent.* In the *Folberth* case, there was a description of the invention in the earlier issued patent, whereas, in the case at bar, the description does not appear in the patent.

C. To negative abandonment, the invention of a divisional patent need not have been *claimed* in its parent application.

So far as *claiming* preheating is concerned, it is true that Warth *might* have presented such claims in his 1930 divisional application. But the point raised by respondent for decision here, is as to whether Warth's failure to do so constitutes an abandonment of his right later to claim preheating in the divisional patent and whether the Patent Office was correct in according him, following its established practice, the filing date of his original application because he had had a disclosure of preheating continuously after his original filing before the Patent Office in patent applications.

This Patent Office practice was recognized and approved in the following cases, in each of which it was specifically held that the right to a patent is preserved, and abandonment negatived, by a continuing disclosure, *even in the absence of a continuing claim.*

Ex parte Replogle, 25 U. S. Pat. Q. 121, (Pat. Off. Board of Appeals—July 23, 1932; see appendix, pp. 41-44);
Lee and Hogan v. *Vreeland,* 1923 C. D. 94;
Ex parte Henry, 1893 C. D. 88;
Von Recklinghausen v. *Dempster,* 34 App. D. C. 474, 476, 477;
Forbes v. *Thomson,* 1890 C. D. 61, 63;
Hopfelt v. *Read,* 1903 C. D. 319, 321.

As we show in our main brief (p. 14), this practice is in accord with the rule laid down by this Court in *Chapman* v. *Wintroath,* 252 U. S. 126, wherein the Court said that a divisional application is entitled to the "priority of right" of the parent application for any invention disclosed in it, even though it "is not claimed therein".

Respondent urges (Br. p. 9) that the case at bar resembles the *Webster* v. *Splitdorf* case, because, respondent says, "in each the inventor *deliberately* failed to insert a claim while having ample time and opportunity to do so and only filed his divisional application after another party had obtained a patent for the invention", and that, in each case, the action of the inventor was due, in the language of this Court in the *Webster* case, to "an exigent afterthought rather than a logical development of the original application".

But the facts in the case at bar are essentially different from those in the Webster case, as we shall now show.

Although Warth failed to present claims specific to preheating in his original application, there is nothing to indicate that such action was *deliberate,* as was the fact in the *Webster* case where the patentee *intentionally* refrained from making the claims, because, as this Court said (p. 465), "he considered their subject-matter one merely of design and not of invention".

Moreover, it is admitted that Warth did not present claims in the application for the divisional patent *broader* than those he presented in his original application, as was

done in the *Webster* case. The Court of Appeals held (III, 1835) that Warth's original application had claims which dominated preheating. Hence, in the case at bar, in contrast with what this Court found in the *Webster* case (pp. 465, 467), Warth did not bring "forward claims broader than those originally sought" or which were "expansions of the original claims". In view of this, it is not correct to characterize Warth's divisional application as not being "a logical development of the original application".

Again, in contrast with the facts in the *Webster* case, Warth was not inspired to present the specific preheating claims in an effort to cover what others had done or what had been in general use. As the District Court correctly found (III, 1803-1804):

> "As soon as it came to Warth's attention that any one else was claiming the invention he, *being unaware of what methods others were using, and having no knowledge of defendant's using the preheating method,* proceeded as the statutes permitted, and in accordance with the practice recognized by the Patent Office and the courts. Overland v. Packard Co., 274 U. S. 417.
>
> "In making the claims to the preheating step Warth was covering what he had invented, *without any intent to expand his disclosures to cover later methods which had come to his attention.* This has been approved by the Courts. Carson v. American Smelting and Refining Co., 4 Fed. (2d) 463, 470; Remington Cash Register Co. National Cash Register Co., 6 Fed. (2d) 614; Overland Co. v. Packard Co., supra."

Although the facts in the case at bar are quite different from those in the *Webster* case, they closely parallel the facts in *Chapman* v. *Wintroath*, 252 U. S. 126.

In the *Chapman* case, the original Chapman application disclosed, but did not specifically claim, the invention of the later-filed divisional application. For six years, no claims to the divisional invention had been presented by Chapman. Such claims were first presented by Chapman in a divisional application only because the Wintroath pat-

ent, containing these claims, had issued, the Patent Office having inadvertently failed to declare an interference between the original Chapman application and the Wintroath application, as it should have done.

Similarly, in the case at bar, Warth was prompted to present his specific preheating claims in a divisional application, because of the grant of the Johnson patent containing these claims, the Patent Office having inadvertently failed to declare an interference between the Johnson application and the original Warth application while the latter was pending. As pointed out in our main brief (p. 9), if such an interference had been declared, Warth would then, *while his original application was pending,* have had knowledge of Johnson's preheating claims, which then stood allowed, and would then have appreciated the necessity for asserting claims specific to preheating.

Like the inventor in the *Chapman* case, Warth could have presented the preheating claims earlier, had the necessity for doing so been apparent. But also like Chapman, Warth did present the preheating claims before any statutory bar had arisen and well within two years after the Johnson patent issued, as approved by this Court in the *Chapman* case.

Moreover, it would indeed be a harsh application of the equitable rule of laches to recognize Johnson's inadvertently issued patent as creating an intervening right, since the uncontradicted evidence is that Johnson, before the earliest date respondent now asserts for his machines with preheating, visited petitioner's plant where he observed the use of the Warth preheating method and thus acquired knowledge of it. (Main Br. p. 32.)

II. Respondent's Argument (Br. pp. 14-22) that the Divisional Patent is Not a Proper Division of the Warth 1930 Application and that the Latter is Not a Proper Division of the Original Warth Application.

Respondent's argument (Br. pp. 18-22; pp. 40-43) on the right of a patentee to file a divisional application "after a patent has once issued" omits consideration of what constitutes a very important fact here; that is, that before the Warth parent patent issued, he had filed a divisional application continuing the disclosure of preheating and that such divisional application was pending when the application for the divisional patent for preheating was filed. Consequently, from the filing date of the original application until the grant of the divisional patent, there was continuously before the Patent Office, in a pending Warth application, a disclosure of the preheating method.

Admittedly, if there had been no such continuing disclosure, the divisional patent would not have been entitled to the filing date of the original application.[1]

The cases cited by respondent (Br. pp. 19-21) are not in point, because they merely state the rule that there must be continuity of disclosure and with this we agree. For instance, in *Spitteler* v. *Krische,* 1908 C. D. 374 (Resp. Br. p. 20), the Court of Appeals said that "there was no application pending in the Office as a foundation for a division." And in *Wainwright* v. *Parker,* 1909 C. D. 379, the Court said "there was nothing left pending before the Patent Office upon which it could act, or to which the latter application could attach". That also was the rule followed in *Gladding-McBean* v. *Clark,* 16 F. (2d) 50 (Resp. Br. p. 19).

On the other hand, where, as in the case at bar, **the disclosure has been continuous through successive applications, the settled Patent Office practice approved by the Courts is to give to each divisional applica-**

[1] However it would be entitled, at least, to its own filing date.

tion the benefit of the filing date of the original application.

This practice is clearly set forth in the decision of the Board of Appeals of the Patent Office in *ex parte Replogle*, 25 U. S. Pat. Q. 121 (July 23, 1932), which is quoted in the appendix, pages 41-44. In that case, there were three applications designated as A, B and C. Case C was not filed until after Case A had matured into a patent. It was copending, however, with Case B, which was filed before Case A matured into a patent. Because of this continuity of disclosure, Case C was given the benefit of the filing date of Case A. The Board of Appeals said:

> "Appellant having pending in this Office a continuing chain of applications A, B and C which describe the common subject-matter and to which claims could have been directed at any time, we do not consider that there is evidence of either abandonment of the subject-matter. * * * or of dedication to the public."

The Board of Appeals also said "* * * claiming is not necessary, but only the presentation of the common subject-matter in a continuing chain of applications" to entitle the last of the three filed applications to the benefit of the filing date of the original application.

Therefore, when the Patent Office accorded Warth's application for the divisional patent the filing date of his original application, it was following its established practice.

The practice followed by the Patent Office in the *Replogle* case was specifically approved in each of the following cases:

> *Benedict* v. *Menninger* (C. C. P. A.) 64 F. (2d) 1001;
> *Field* v. *Colman*, 40 App. D. C., 598.

In *Benedict* v. *Menninger, supra*, the Court accorded an application filed in 1927 the benefit of the filing date of an earlier application filed in 1923, with which the 1927 case was *not* copending, because, as in the case at bar, there had been an intervening application copending with both. The Court said (1002, 1003):

"It is conceded that both the Menninger application of May 8, 1923, and that of December 10, 1925, disclose the subject-matter of the counts, but same was not specifically claimed in either. Claims of the first may have been broad enough to include it.

* * *

"It thus appears that from May 8, 1923, Menninger has had continuously pending in the Patent Office applications disclosing the subject-matter of the counts with the right, so far as disclosure is concerned, to make the claims at any time. *Continuity of dislosure* was preserved. Field v. Colman, 40 App. D. C. 598; Alexander Milburn Co. v. Davis-Bournonville Co., 270 U. S. 390, 46 S. Ct. 324; 70 L. Ed. 651."

A. Disclosure of an invention in an application, even without a claim therefor, is sufficient basis for a divisional application for that invention.

Respondent's argument (Br. 16-17) contradicting the foregoing proposition, is directly in conflict with each of the decisions referred to, *ante* page 10, and particularly the decision of this Court in *Chapman* v. *Wintroath*, 252 U. S. 126, where this Court specifically said that a divisional application is entitled to the priority of the parent application even though the invention of the divisional case was "not claimed therein."

Respondent's statement (Br. p. 17) that "the Circuit Court of Appeals in the case at bar followed what we understand to be the well settled rule viz., that a divisional application to be availed of must be for the same invention and must claim it" shows clearly the error into which that Court fell.

What the Court of Appeals did was directly in conflict with the rule which has been followed for over fifty years by the Patent Office and the law as laid down by this Court in the *Chapman* case. In that case, this Court accorded Chapman's divisional application the benefit of the filing date of his original application, notwithstanding that the subject-matter of the divisional application had not been

claimed in the original application. Chapman had copied into his divisional application claims from the Wintroath patent and this Court said (p. 126) that "the combination of the Wintroath patent was not specifically claimed [in the original Chapman application]".

The decisions cited by respondent (Br. pp. 17-18) do not support respondent's contention that a divisional application must be directed to subject-matter *claimed* in the original application. *In fact, if they did, they would be overruled by the Chapman decision of this Court.*

Respondent's quotation (Br. p. 17) of a *part* of a sentence from the *Milburn* case is grossly misleading. Removed from its context, respondent's quotation appears to state the antithesis of what this Court actually held, namely, that a claim is *not* necessary to establish a reduction to practice date. We reproduce below the context, with respondent's quotation in brackets:

> "The question is not whether Clifford showed himself by the description to be the first inventor. By putting it in that form it is comparatively easy to take the next step and say that [he is not an inventor in the sense of the statute unless he makes a claim]."

There can be no real excuse for such a deception and incomplete quotation.

In *Jones* v. *Larter*, 1900 C. D. 111 (Resp. Br. p. 17), the question involved was double patenting, since the earlier issued patent described and *claimed* the subject-matter which the applicant sought to protect in his second alleged divisional application. The Commissioner held (at 114):

> "It would seem that these claims covering *the same thing as the claims in the prior patent* and differing therefrom only in scope cannot properly be allowed in this case. To do so would be to allow two patents to the same party covering the same invention."

After pointing out that the subject-matter was described in the original patent, the Commissioner said (at 115):

> "This was clearly a case where the claims could probably be made by reissue if at all * * *."

Consequently, although the quotation from *Jones* v. *Larter*, as removed by respondent from its context, might *appear* to conflict with the practice followed by the Patent Office in the case at bar, it does not do so, *in fact*, as study of the decision clearly shows.

Nor does *ex parte Stimson*, 1916 C. D. 20, cited by respondent, (Br. p. 18) support its position. In that case, the Commissioner merely refused to permit claims for another invention to be injected into a pending application in which claims to one invention had already been allowed, since this would result in a single application with claims therein to two entirely separate and distinct inventions. But the Commissioner *did not hold that Stimson could not file a divisional application presenting such claims, and in such application, be entitled to the filing date of the pending allowed application.*

Indeed, he could not have so held without directly overruling *Hopfelt* v. *Read*, 1903 C. D. 319, 321, where the Commissioner had said:

> "The fact that the Office practice may prohibit the prosecution and allowance of the claims in an earlier application *does not prevent an applicant from availing himself of the earlier date of filing* as his date of constructive reduction to practice *when he files a later application containing the same description and the claims based upon the same.*"

B. Warth's divisional applications complied with the Patent Office rules to the satisfaction of the Patent Office.

Respondent (Br. p 14) charges generally that Warth did not comply with the Patent Office rules as to divisional applications. It also argues that the statement in the divisional patent that it is a division of the 1930 divisional application and that that, in turn, is a division of the original application, is clearly erroneous.

Obviously, the Patent Office does not agree with respondent, since it endorsed the Warth divisional patent with

the alleged erroneous statement,[1] as shown on the face of the patent (I, 554). Furthermore, in recognition of the correctness of that statement, the Patent Office, in Warth's interference with Johnson, accorded the divisional patent the filing date of the original application (II, 660 *et seq.*).

Clearly, therefore, the Patent Office considered that the Warth divisional applications sufficiently complied with its rules and procedure and they did so comply. Even if they did not do so completely, the Patent Office has waived any objection thereto, a thing which the Courts have recognized that the Patent Office may do without affecting validity of the patent. See cases cited, *post*, page 19.

Respondent also suggests (Br. p. 15) that the Warth 1930 application was not a proper division because, while the Patent Office had required claims for the adhesive *per se* to be divided out of the original application, the 1930 application claimed the adhesive as applied to a strip material.

There is no point to this criticism, since divisions may be filed even though not required by the Patent Office. In each of the cases of *Chapman* v. *Wintroath* and *Overland* v. *Packard*, divisional applications were approved by this Court, *though they had been filed without Patent Office requirement.*

Warth, therefore, was free to file a divisional application for *any separate invention disclosed in his original application*, and he was not restricted to the one referred to in the Patent Office requirement for division.

Respondent also suggests (Br. p. 15) that Warth's statement in the original application, when cancelling the adhesive claims (III, 1251), was not notice of a possible divi-

[1] This file endorsement was pursuant to Commissioner's Orders No. 1832 and No. 2010 quoted in the appendix pp. 44, 45. As the orders show, the endorsement is an act requiring the exercise of judgment on the correctness of the specification statement that the application was a division since the orders do not permit an improper reference.

sional application on any separately patentable portion of his method, including preheating. This is wholly immaterial. **We know of no rule, decision or statute requiring an applicant to state in his application what parts of his disclosure he may, in the future, embody in divisional applications.** In fact, Rule 44 of the Patent Office[1] specifically prohibits reservation of disclosed subject-matter for a future application.

Moreover, it has always been recognized, both by the courts and the Patent Office, that procedural rules, such as those to which respondent refers and which include Rule 43 mentioned by respondent (Resp. Br. p. 57) do not affect the status of a patent issued without strict compliance therewith.

For instance, speaking of failure to comply with a Patent Office Rule relating to supplemental oaths, the Court, in *Heller Bros.* v. *Crucible Steel* (297 F. 39, 43; C. C. A. 3) said:

> "At most, as we understand it, it is but a rule of Patent Office procedure, promulgated upon the authority of R. S. §483 (Comp. St. §745). If valid, and we deem it unnecessary to pass upon that, it has no bearing upon the question of validity of a patent when issued."

See also *Heap* v. *Tremont et al.*, 82 F. 449, 459, (C. C. A. 1); *Deere* v. *Arnold*, 95 F. 169, 170, (C. C. N. D. N. Y.).

In *Ex parte Roberts*, 1887 C. D. 61, 63, the Commissioner said:

> "Rule 42 [now Rule 43] provides that when there are two or more applications pending—
>
> relating to the same subject-matter of invention, all showing but only one claiming the same thing, those not claiming it must contain disclaimers thereof, with reference to the application claiming it.

[1] 44. A reservation for a future application of subject matter disclosed but not claimed in a pending application will not be permitted in the pending application.

"But there is nothing in the rules, nor is there any statutory provision to the effect that a failure to file such disclaimer should deprive applicant of his right to a patent, *or invalidate one issued upon the second application. The rule does not and could not constitute a statutory bar*".

III. Respondent's Argument (Br. pp. 22-24) that the Johnson Patent Properly Issued Without an Interference With the Original Warth Application.

Respondent denies that allowed claim 35 of the Johnson application should have been suggested to Warth while his original application was pending and an interference declared, as asserted in our main brief (pp. 8, 9). Respondent either misses the point or is unaware of the Patent Office rules and procedure with respect to interference declarations.

Our point is that an interference should have been declared on claim 35 of the Johnson application, which stood allowed *when the* **Warth** *application was ready for allowance and before the* **Warth** *patent was issued.*

It is the practice of the Patent Office to make a search through copending applications before issuing any patent, as respondent agrees (Resp. Br. p. 24). The unassailable fact is that on December 11, 1930 when the Warth original application was allowed (III, 1288), this dominating claim 35 (II, 713) stood allowed[1] in the Johnson application and should have been suggested to Warth under Patent Office Rule 96 (Main Br., p. 43), *particularly since the Johnson application was not filed until over two years after the Warth application.*

Consequently, respondent's argument (Br. p. 24) that, when the *Johnson* patent issued, there were *then* no Warth method claims on file, is entirely beside the point. The important fact is, as we have just stated, that there was an

[1] It had been allowed in the official action of September 10, 1930 (II, 717).

evident and undeniable conflict between the original Warth and the Johnson applications when the *Warth* original application was ready for allowance and this conflict should have been settled by the declaration of an interference before the parent Warth patent issued. If that had been done, Warth would *then* have seen, and asserted the preheating claims which then stood allowed in the Johnson application and the question of priority would have been settled without delay and before the Warth parent patent issued. Certainly *petitioner* should not be charged with laches or abandonment of invention because of this inadvertent omission by the Patent Office.

IV. Respondent's Argument (Br. pp. 24, 25) that the Cancelled Preheating Description in the File of the Original Warth Patent Was a "Publication."

Respondent first argues that, since the entire file wrapper of the Warth application for the parent patent was open to the public on the grant of the patent and thus became a matter of public record, anyone examining the file would note the cancellation of the preheating matter therefrom and "would naturally assume that this matter and any claims therefore were abandoned by the inventor and dedicated to the public."

Since there is no statute or rule requiring an applicant, when cancelling subject-matter from an application, to state that he intends to file a divisional application covering such subject-matter, any such "assumption" as respondent urges would be wholly unwarranted. Therefore, respondent's suggestion as to what one *might* unwarrantedly assume does not justify an inference that Warth intended to abandon the subject-matter, as we show page 19 *ante*. To establish abandonment, intent must be *proved* and is not to be presumed.

Furthermore, as to the laches defense, it is immaterial whether one *might* or "would naturally" make such an assumption, since, to establish laches, it must be shown that

someone was, *in fact*, thereby misled into doing something which otherwise would not have been done (*Galliher* v. *Cadwell*, 145 U. S. 368, 372, 373—Main Br. p. 21). **Respondent does not even suggest that it, or anyone else, was so misled.**

The necessity for such a showing is emphasized by this Court in the *Webster* case, where, by analogy to an application for reissue, the Court said (at p. 567) that one " 'who seeks to revive his right which he has allowed to lie unclaimed' " is deprived by laches " 'from enforcing it to the detriment of those who **have**, in consequence, **been led to act** as though it were abandoned'."

The Patent Office file wrapper is not a "printed publication" within the meaning of the statute (R. S. 4886).

Respondent (Br. p. 54) makes the wholly unwarranted assertion that the Warth parent application is a "printed publication" within the meaning of the statute (R. S. Sec. 4886), evidently intending to suggest that the cancelled preheating description in the original patent file is, therefore, a statutory bar to the divisional patent, being part of a "printed publication."

An inventor's right to a patent is not barred if the invention becomes known more than two years before he files his application provided such knowledge is not obtained from a "*printed* publication" or by a "public use" or "sale" of it more than two years before his application (R. S. Sec. 4886). As this Court said in *Elizabeth* v. *Pavement Co.*, 97 U. S. 126, 136:

> "* * * It is not a public knowledge of his invention that precludes the inventor from obtaining a patent for it, but a public use or sale of it. In England, formerly, as well as under our Patent Act of 1793, if an inventor did not keep his invention secret, if a knowledge of it became public before his application for a patent, he could not obtain one. To be patentable, an invention must not have been known or used before the application;

> but this has not been the law of this country since the passage of the act of 1836, and it has been very much qualified in England. Lewis v. Marling, 10 B. & C. 22. Therefore, if it were true that during the whole period [six years, p. 133] in which the pavement was used, the public knew how it was constructed, it would make no difference in the result."

Similarly, this Court held in *Corona* v. *Dovan*, 276 U. S. 358, 372, 373, that a paper read before a chemical society, but not published as a "printed publication" more than two years before the application date of the patent in suit, was not a defense under the statute.

In *Fessenden* v. *Wilson*, 48 F. (2d) 422, 425 (C. C. P. A.) the Court specifically held that a description in the file wrapper of a patent, but not appearing in the patent because of cancellation during the prosecution, is not a "printed publication" under the statute (R. S. 4886). The Court said:

> "For obvious reasons, the filing of an application, the description of which is canceled before it results in a patent or comes to the public notice, is not such a published description of the invention as is within the inhibition of the statute. [Sec. 4886.] Milburn Co. v. Davis-Bournonville Co., supra."

Consequently, it is not true that the file of the application for the Warth parent patent is a "printed publication" and thus a statutory bar within the meaning of the statute (R. S. 4886). Nor is it material for how long the public may have known of the preheating invention from the Warth application file before Warth filed his divisional application, since that file has no more adverse effect under the statute (R. S. 4886) than an oral description of the Warth invention or a public experimental use thereof would have had.

V. Respondent's Argument (Br. pp. 26-32) that There Were Adverse Intervening Rights Against the Divisional Patent.

In an attempt to disprove our statement (Main Br. pp. 10, 11) that there were no adverse intervening rights more than two years before the application for the divisional patent was filed, respondent asserts that machines operating according to the preheating invention were so used by it and others.

In urging this defense here, respondent asks this Court to review an issue of fact decided adversely to respondent by the District Court on conflicting evidence[1] and without contrary finding by the Court of Appeals, although respondent strenuously contended before that Court that the finding of the District Court was in error.

Every argument advanced here by respondent on the point of adverse intervening rights was expressly considered and rejected in the opinion of the District Court, who saw and heard all of the witnesses.

The District Court said (III, 1803):

> "The machines purchased by defendant from Johnson in 1928, had no preheater, and I am convinced that defendant made no further purchase[2] from Johnson until 1933, therefore the defendant has not proved any use of the preheating method, to anticipate the filing date of the first divisional application Nov. 7th, 1930 or the filing date of the second divisional application April 4, 1933."

---

[1] In its brief before the Court of Appeals, respondent said: "Plaintiff contended and the Court below found *on conflicting evidence* that the first machine bought from Johnson by defendant did not have a preheater."

[2] Respondent's assertion (Br. p. 27) that this statement is plain error is based on the letter rather than the obvious meaning of the Court's language. Since preheating was the subject-matter of the finding, the Court's reference to "further purchase" clearly refers only to machines with preheating. As we show, *post*, pp. 26-31, the Court's finding as to machines with preheaters is correct.

We submit that this Court should accept this undisturbed finding of fact of the District Court in accordance with the ruling in *Adamson* v. *Gilliland*,[1] 242 U. S. 350, 353:

> "Considering that a patent has been granted to the plaintiff the case is preeminently one for the application of the practical rule that so far as the finding of the master or judge who saw the witnesses 'depends upon conflicting testimony, or upon the credibility of witnesses, or so far as there is any testimony consistent with the finding, it must be treated as unassailable' (citing) Davis v. Schwartz, 155 U. S. 631, 636."

Respondent argues (Br. p. 26) that, because the two lower Courts disagreed on issues *other* than intervening rights, this Court should disregard the rule of *Adamson* v. *Gilliland* and now re-examine the record on this fact issue of intervening rights. In support of its position, respondent cites *Thomson Spot Welder* v. *Ford*, 265 U. S. 445 and *Berlin Mills* v. *Procter & Gamble*, 254 U. S. 156. In the former case, two Courts of Appeals had reached different findings as to the fact of invention, and this Court decided that, under such special circumstance, there should be an exception to the well-settled rule, and so it examined the record to resolve the conflict. In the latter case, there had been a similar conflict of opinion as to the fact of invention, the District Court and one of the Judges of the Court of Appeals disagreeing with the other two Judges of the Court of Appeals on this fact.

Consequently, neither of the cases cited by respondent is applicable to the case at bar, where the District Court's finding was not disturbed by the Court of Appeals.

---

[1] The cases are uniform to the effect that this Court accepts a finding by a trial court or a master made from conflicting evidence involving the credibility of witnesses, where the finding has not been disturbed by the Appellate Court. *United States* v. *United Shoe Machinery Co.*, 247 U. S. 32, 37, 41; *Mason* v. *United States*, 260 U. S. 545, 556; *Cramer* v. *United States*, 261 U. S. 219, 226.

The record supports the District Court's finding that there is no proof of adverse intervening rights.

In case this Court should desire to examine the record to ascertain whether there is support for the finding by the District Court that adverse intervening rights had not been proved, we state the facts and answer respondent's arguments on the point as follows:

Preliminarily, we point out that, in order to invalidate a regularly-issued patent, proof of prior use must be free of any reasonable doubt.[1] Intervening rights are, of course, only a species of prior public use.

It should also be noted that, to prove intervening rights against the divisional preheating patent, it is not sufficient merely to show that "spotting machines" were used or sold. It must be shown that such machines were designed and operated so as to apply heat to the spot by means of a PREHEATED CORK, which is the distinctive step of the invention of the divisional patent.

1.—ALLEGED INTERVENING RIGHTS ARISING FROM RESPONDENT'S ACTIVITIES.

Respondent asserts (Br. p. 27) that certain machines purchased from Johnson and used by it in 1928 and 1929 (Exh. Q., R. p. 881, 882) had means for preheating the cork. There is no physical or documentary evidence of this. The machines in question are identified in the invoices (Exh. Q.) merely as "assembling machine", admittedly a term applied to machines used to insert *cork discs in the metal shells* of the caps and *not* to apply spots to the cork. The machines are not in evidence and no excuse was given for failure to produce them.

Respondent asserts, however (Br. p. 27), that the designation "extra head, roll feed" on the invoices of these 1928, 1929 machines shows that "the machines had the preheat-

---

[1] *Cantrell* v. *Wallick*, 117 U. S. 689, 696; *Radio Corp.* v. *Radio Laboratories*, 293 U. S. 1, 8; *Barbed Wire Patent Case*, 143 U. S. 275, 284.

ing device". Obviously, the phrase "extra head, roll feed", in itself, does not identify the machine as being a "spotting" machine and much less a spotting machine utilizing preheating. Nor is there any testimony which connects this quoted phrase with either a spotting machine or one utilizing preheating. The testimony (XQ's. 479/87, (I, 260-261) cited by respondent (Br. p. 27) in no way relates to the phrase "extra head, roll feed" or even to the invoices which carry it.

The complete answer to respondent's assertion as to the September 1928-1929 machines of the invoices, Exh. Q, is to be found in the testimony of respondent's witness Johnson (I, 173) that, **prior to October 5, 1928,** when he was experimenting with a machine previously sold to Armstrong, **no machine sold by him had means for preheating the cork** (XQ. 121).

Respondent's Secretary, Cohn, testified that the mechanism in the machines of Exh. Q for applying center spots *"was the same as on the previous machine"* (I, 214, Q. 93). The "previous machine" referred to is the Exh. P. machine purchased in August, 1928 (II, 880) which, *by Johnson's own admission* (I, 13) *did not have means for preheating the cork.* Johnson's admission applies, of course, also to the September 15 machine of Exh. Q (I, 282), and Cohn's testimony indicates that *all* of the machines of Exh. Q were alike, so far as the spotting mechanism is concerned.

Furthermore, if the testimony of respondent's Vice-President, Cohn, that the Exh. Q machines had apparatus to carry out the preheating method be accepted, that leads to a flat contradiction of other testimony by Cohn, in which he is corroborated by another witness, for the following reason:

Cohn has a patent No. 1,921,808 (I, 596), which discloses a method of inserting cork discs in the metal shells, and then the application of spots to the cork, all *in the same machine.* Cohn, in answering Interrogatory 4 (I, 573), swore that the method of this machine had not been used

prior to March, 1932,[1] and Rasmussen, respondent's superintendent, corroborated this (I, 283). Moreover, Cohn, in his application oath, for the Cohn patent, had, of course, sworn[2] that his invention had not been in use for more than two years prior to its filing date of July 20, 1932.

If the testimony of Cohn that the 1928-1929 Exh. Q machines had preheaters be correct, then, since Cohn says (I, 214, Q. 93) that the Exh. Q machines were spotting machines and had also "mechanism for inserting cork discs into the metal shells after the manner of the Clark-Johnson type assembling machines", he is saying that these mechines operated in accordance with the method of the Cohn patent. Therefore, if, as respondent now asserts, the Exh. Q machines were operated in 1928 and 1929 as preheater spotting machines, such assertion is in flat contradiction to its proofs as to the Cohn method which the same witnesses swore had not been used prior to 1932.

In any event, **all of respondent's evidence as to these 1928, 1929 Exh. Q machines, is merely oral testimony of biased witnesses taken seven years after the event without even explanation of the failure to produce the machines and without any corroborating contemporaneous documentary evidence referring to the invention respondent seeks to anticipate.**

Respondent further asserts (Br. 29) that the testimony of a number of witnesses and certain paper exhibits show that a large number of caps with center spots secured by gutta percha "*by the preheating method*" had been made and sold by respondent between *August, 1928*,[3] and the date of the trial.

---

[1] We do not accept this 1932 date as proved. It is supported only by the oral assertions of these two biased witnesses. We use it here merely to show the conflict here between respondent's evidence and its present assertions.

[2] Patent Office Rule 46—Appendix, p. 44.

[3] None of these witnesses even asserted that the caps were made by machines other than those obtained from Johnson and Johnson has testified that (I, 173) that no machine made by him prior to October, 1928 had preheating.

Of the witnesses and exhibits referred to by respondent, the testimony of Ketterer (I, 200) can be eliminated at once, because he merely testified to the purchase of spot crowns from respondent and made no reference to, nor indeed did he have any knowledge of, the method used in making them. The same is true of respondent's Exhs. NNN to TTT (III, 1519-68), because these are merely invoices for spot crowns and, of course, throw no light on their method of manufacture.

The testimony of Cohn (I, 214) we have discussed *supra* and have shown (1) that, if accepted as proving the 1928-1929 machines of Exh. Q to have been spotting machines, it is inconsistent with the Cohn's application oath and sworn answer to Interrogatory 4, and (2) that, in any event, it proves that these machines to have had means for applying the spots like earlier-purchased machines which admittedly did not use preheating.

The testimony of Cohn at I, 258, 259 and Eisen at I, 294 and Rasmussen at I, 281, refers only to a different method to which respondent was obliged to resort, in 1928 at least, for a secondary treatment of *already*-manufactured spot crowns made on a machine purchased from Johnson in July, 1928 and which admittedly did not use preheating. **In other words, this testimony cited by respondent has no bearing whatsoever upon the use of the preheating invention.**

Respondent (Br. p. 30) also refers to its Cohn patent 1,921,808 (I, 596), but does not state what bearing it has on the issue of intervening rights. This Cohn patent was not even applied for until July 20, 1932, less than a year prior to the filing date of the Warth divisional patent and, therefore, is not a bar to the Warth patent under the doctrine of *Chapman* v. *Wintroath,* or under the statute (R. S. 4886). Furthermore, as has been shown, respondent's proofs are that the method of this patent was not used prior to 1932.

2.—Alleged Intervening Rights Arising From Johnson's Activities.

Respondent also contends that the record shows sale and use by others than respondent, of Johnson machines embodying preheating more than two years prior to the filing date of the application for the divisional patent. Rejecting this contention, the District Court held (III, 1803):

> "There is no evidence to show that the Johnson machines sold to others than plaintiff and identified on the list had a preheater, or what was their construction, aside from Johnson's statement, which he changed under cross-examination."

Johnson testified (I, 171-173) that, in March, 1928, he sold a machine to a Cuban concern. He admits that this machine did not utilize preheating the cork. He also testified that, in April 1928, he sold a machine like the Cuban machine to the Armstrong Company. The Armstrong machine was returned as unsatisfactory. According to Johnson's testimony, partially quoted by respondent (Br. 28), Johnson attempted to make this returned machine work. In a letter (Exh. 36—II, 609) written October 5, 1928, Johnson had said:

> "* * * I now have to see what I can do in regard to not having the tinfoil discs stick to the punch."

Johnson also said (I, 173) that he installed two heaters in front of the punch and that he did this about October 5, 1928.

There is no documentary or other physical contemporaneous proof to substantiate Johnson's statements nor is he corroborated by any other witness. Johnson testified that he did not return the machine to Armstrong (I, 172), but that he "made some changes on it" and "sent it to some other customer" (X-Q. 112). The record is silent as to (a) *what* changes were embodied in the machine alleged to have been "sent", (b) *when* the machine was completed and

used (use being essential to anticipate a method), and (c) *to whom* the machine was shipped.

Johnson's uncorroborated oral testimony, seven years after the event, falls far short of proving public use or sale of a particular invention.

In an attempt to support Johnson and prove the sale of other machines by Johnson, respondent (Br. 28, 29) refers to certain affidavits (Exh. U—II, 901-918) filed in the Patent Office in connection with a petition to institute public use proceedings. Not one of these affiants[1] was called as a witness and, obviously, affidavits of this character are not evidence as to the truth of the facts set forth therein. Exhibit U merely proves that such affidavits were filed in the Patent Office.

VI. Respondent's Argument (Br. pp. 30-32) that Petitioner Knew in 1930 that Respondent Was Making and Selling Center Spot Caps and Should Have then Ascertained the Method Respondent Was Using.

While it may be true that respondent was selling center spot caps in 1930 and that this was called to the attention of some of petitioner's employees, that is wholly immaterial as to any issue here.

Obviously a center spot crown does not, *per se*, show how it is made and, in particular, it does not show how or when the heat is applied to the spot in the manufacture of the crown. In fact, *petitioner* was making and selling spot crowns *before Warth's preheating invention*, so that, clearly, the mere existence of a spot crown does not even suggest that a preheating method was used in its manufacture.

Obviously, respondent recognizes this to be the fact, and so it asserts (Br. p. 31) that "It was petitioner's duty to have then ascertained what method respondent was using".

---

[1] Except Johnson who identified his affidavit (I, 165) but contradicted the same under cross-examination (I, 173).

Respondent does not explain wherein this "duty" arose nor *how* such knowledge was to be obtained. Respondent's caps are manufactured in its own plant and certainly there is no suggestion that petitioner had access to that plant or any right to invade it.

Respondent's statements (Br. p. 32) as to the visit of petitioner's Vice-President and counsel to respondent's plant on August 8, 1933, is entirely beside the point because the Warth preheating divisional application had been filed previously (April 4, 1933) so that any information obtained by petitioner's officer at the time of that visit is wholly irrelevant on the question of laches. The uncontradicted testimony (I, 521) is that, prior to filing the divisional preheating application, petitioner had no knowledge of the method respondent was using.

VII. Respondent's Argument (Br. pp. 33-35) that Petitioner's Laches Began With Johnson's Building of Machines for Petitioner in 1929.

Prior to 1929, petitioner's spotting machines had been built in its own plant (I, 521). In 1929 petitioner needed additional machines for its Canadian plant and had Johnson build them (I, 522). These machines were simply tested and shipped to Canada (I, 423).

Respondent suggests that the machines differed considerably in construction from the machines used prior to that date by petitioner. There is nothing in the record to support this assertion, but, even assuming that the machines corresponded to the Johnson patent, it will be evident that the spotting mechanism substantially corresponded to petitioner's earlier-built machines. The District Court did *not* find that the machines are "radically" different, as suggested by respondent (Br. p. 34).

In any event, it is quite immaterial whether the machines supplied by Johnson corresponded to machines petitioner had previously built, since, in constructing them, Johnson was merely acting for petitioner.

There is no proof that Johnson had previously built, or was at that time building, preheating machines for others.

As we have shown (Main Br. 22-23) *use* of the preheating invention by petitioner more than two years before filing the divisional application did not invalidate that patent. Clearly, if the patent was not invalidated by petitioner's *use*, it was not invalidated by petitioner's building machines for such use, and it is equally clear that the legal effect was the same when it had its machines built for it by someone else at another plant.

VIII. Respondent's Argument (Br. pp. 36-39) that Its Purchase of Machines from Johnson Before the Issue of His Patent Gives Respondent a License Under the Warth Divisional Patent.

A. The Warth-Johnson interference.

Respondent contends that, because it purchased machines from Johnson before the Johnson patent issued and petitioner later purchased the Johnson patent, respondent has a license under Warth's divisional patent claims which were awarded Warth by the Patent Office in an interference with the Johnson patent.

In making this argument, respondent insinuates that the Johnson-Warth interference was a collusive proceeding.

It is not a fact, as respondent asserts (Br. p. 36), that the Warth-Johnson, interference was not *bona fide*. It was instituted before petitioner purchased the Johnson patent. The agreement to purchase the patent was entered into on December 12, 1933 (II, 925), whereas the interference had been previously declared on April 20, 1933 (III, 1337), and petitioner did not receive title until after the interference terminated (p. 34 *infra*, footnote).

The record shows that Johnson, in order to avoid litigation, sold his patent to petitioner while the interference was pending (I, 164; 334) and received a license under the Warth parent patent, as well as under claims which might

be obtained by Warth in the interference.[1] In accordance with a stipulation, the matter was then submitted to the Patent Office (III, 1616) on a record involving, as the only issue, whether the original Warth application filed in 1927 disclosed the subject-matter of the claims, which respondent now admits was the fact. The Examiner of Interferences held that the original application disclosed preheating, and, accordingly, awarded priority to Warth (III, 1660).

The charge of collusion was made before the District Court and also before the Court of Appeals. The District Court found that the award of priority was in accordance with the facts and that petitioner acted as it should have done in submitting the matter for final decision to the Patent Office (III, 1880-1802).

It simply is not the fact, as respondent asserts, (Br. p. 36) that petitioner "could have and should have," under Patent Office Rule 94, determined by election the question of priority between Johnson and Warth. Under the rule, petitioner could not have elected in favor of Warth since the Johnson patent had issued. The decision of the Commissioner in *Chillis* v. *Weisberg*, 1928 C. D. 24, cited by the District Court (III, 1801) so interprets the rule and that decision fully supports the action of petitioner in submitting the matter for determination by the Patent Office as it had to do, under the decision, knowing that Warth was the prior inventor.

Although now attacking the interference as collusive, respondent has not even attempted to offer evidence showing invention of preheating by Johnson prior to the filing date of the original Warth application. The admitted disclosure of the invention by Warth in his original application, therefore, under the rule of this Court in *Chapman* v. *Wintroath, infra,* establishes him as the prior inventor.

Respondent's attack upon the Warth-Johnson interference, therefore, is without merit, since it does not question

---

[1] Under the agreement with Johnson, the assignment of the Johnson patent and the license to Johnson were put in escrow (I, 335) until final determination of the interference in the Patent Office. It remained in escrow until the Patent Office awarded the claims to Warth, the Patent Office being fully informed as to the situation (I, 335). The District Court so found (III 1800, 1801).

the propriety of the award to Warth or the fact of Warth's 1927 application disclosure of the preheating invention which is the basis for that award.

B. Respondent's claim to a license.

Respondent first says that it is licensed under the Johnson patent by reason of the purchase of machines from Johnson before the Johnson patent issued.

Then, in some way not clear to us, respondent proceeds to the conclusion that it is also licensed under the Warth divisional patent, because the Johnson patent is now also owned by petitioner.

We have already shown that Warth preceded Johnson by nearly two years, and, therefore, is clearly the inventor of the subject-matter of the divisional patent claims. Consequently, such claims were invalid in the Johnson patent, as the record plainly shows.

Respondent's claim to a license is based solely upon its relationship with Johnson, *i. e.*, the purchase of machines from him. Obviously, any license which respondent obtained by such purchase could not extend beyond inventions which Johnson owned. He did not own the preheating invention, since the Patent Office found that the claims thereto in the Johnson patent were improperly granted to Johnson and that Warth was the prior inventor. In other words, by the interference decision, the preheating claims of the Johnson patent were, in effect, cancelled from the Johnson patent. *Petitioner's ownership of the preheating invention is not through the claims thereto improperly issued in the Johnson patent, but through the grant of such claims in the Warth divisional patent.*

Petitioner was in no wise a party to the transaction between Johnson and respondent or to the improper issuance of the preheating method claims in the Johnson patent. Therefore, when petitioner acquired the Johnson patent after the preheating method claims, in effect, had been cancelled therefrom (*ante*, p. 34, footnote), that transfer

gave respondent no rights under petitioner's preheating invention which Johnson did not and never had owned.

If respondent were being sued on the *Johnson* patent, the defense of license might apply, and the decision cited by respondent (Br. p. 36) would be in point. But this suit is on the *Warth* patent, and respondent's plea of license thereunder is really that the purchase of the Johnson patent by petitioner gave respondent greater rights than it had previously derived from Johnson or which Johnson had ever been in a position to give.

In *Hartford-Empire* v. *Nivison*, 58 F. (2d) 701, 705, 706 (C. C. A. 6th), the facts were the same as in the case at bar and the same contention made by respondent here was rejected. The Court said:

> "It is claimed that the defendant occupies the status of a licensee. The trial court denied the contention. It is true, of course, that the defendant as purchaser of a Miller feeder acquired a right or license to use that feeder under any patents owned by Miller, who manufactured the feeder, or under any patents of the Miller Glass & Engineering company, which sold the feeder to the defendant. It is, however, equally true that the **purchase of the Miller applications by the plaintiff did not give the defendant, as licensee of Miller, any license to other patents or applications outstanding, and the suit here in question is upon a patent in which Miller had no property interest and which, rightly or wrongly, was held in the Patent Office to take precedence over the Miller applications.** As to whether the plaintiff obtained this ruling in the Patent Office by the use of unfair methods is not for us to determine. For present purposes we accept the Patent Office ruling, in view of which **it cannot be held that the license obtained by the defendant in the purchase of the Miller feeder included the right to use such feeder as against a patent issued upon an application in which Miller had no interest.**"

Just as in the Hartford-Empire case, respondent here is asserting that the finding of the Patent Office in favor of

Warth was obtained wrongfully. **But respondent had full opportunity to show that the Patent Office award was in error and offered no evidence to support such a contention.** On the contrary, it **admits** Warth's prior inventorship, since it concedes that Warth disclosed the invention in his original application long prior to any date claimed for Johnson.

IX. Respondent's Argument (Br. pp. 44-47) Denying Infringement of the Reissue Patent.

Respondent contends that, since it applies heat to the spot by a heated cork, instead of a heated punch, it does not infringe the claims of the reissue patent, and that the Court of Appeals was correct in limiting those claims to a heated punch. In our main brief (pp. 26-32), we have pointed out the error of the Court of Appeals in so limiting the claims.

Respondent has not replied to our analysis of the claims or attempted to justify the Court of Appeals' erroneous interpretation of the claim language discussed in our main brief (p. 27). Respondent takes exception only to our statement that the heated punch was not originally described in the parent Warth application, and, contradicting this assertion, quotes the following language which appeared (III, 1246) in the original specification:

> "In carrying out the invention according to what is now considered the best practice the coating will be softened by heat after the crown is assembled. This may be accomplished in any suitable manner, as by a *heated plunger* or *a plunger and heated table.* The heat softens the coating and renders it adhesive and the pressure serves to unite the metal foil spot to the cork."

Respondent evidently interprets the reference to a heated *plunger* to be equivalent to a disclosure of a heated *punch.* In so doing, it overlooks the fact that the sentence referring to the heated *plunger* deals with the application of heat and pressure "*after* the crown is assembled." That is to say,

this sentence refers to what occurs at the station *following* the punching operation. (See drawing opposite page 5 of our main brief—"Fourth Step"). It was so interpreted by the Patent Office in the prosecution of the Warth divisional application after a question had been raised (III, 1445), as to the justification for the showing of the heated *plunger,* in Figure 6 (III, 1465) of the application drawing, which plunger was described (III, 1434) as "additional pressure means which may be utilized following the action of the punch." Warth's attorneys pointed out to the Patent Office (III, 1455) that this reference to a "heated plunger or a plunger and a heated table" has to do with the operation at the station *following* the punch, and not at the punching station, and the Patent Office agreed.

We have already pointed out (*ante,* pp. 4, 5) that there is no file wrapper estoppel arising out of claim cancellation to compel a limited meaning to the reissue claims and, therefore, need not discuss respondent's arguments on this point under infringement.

Nor need we discuss respondent's statement (Br. 45) as to the effect of an inventor's belief in the scope of his claim as an excuse for delay. That we have fully discussed in our Main Br. pp. 24-26; 33, 34.

Under the guise of support for the assertion (Br. p. 45) that respondent has always used "a cold cutting plunger," respondent's brief (pp. 45, 47) repeats its argument, rejected below, as to an alleged prior use of the Warth invention by respondent in 1924. Respondent uses the question of infringement as an excuse for rearguing rejected evidence of an alleged prior use which the District Court (III, 1788) described as "a temporary makeshift, which was abandoned as soon as it [respondent] was able to perfect the making of the White Rock [mechanically held spot] crown." While several witnesses were examined by respondent in connection with this defense, on the vital point as to the *method by which the spots were adhered to the corks,* respondent's proofs consisted only of the oral

testimny of *two witnesses,* namely, its Secretary, Cohn, and its Superintendent, Rasmussen, given ten years after the alleged defense, based entirely on recollection and without one scintilla of contemporaneous physical corroborating evidence.

The District Court who saw and heard the witnesses fully discusses their testimony (III, 1788, 1789) and rejected this prior use defense on the ground that the:

> "testimony is too uncertain, based only on recollection of what is alleged to have happened ten years before, to furnish proof beyond reasonable doubt, to anticipate the Warth method patents in issue."

The Court further said that whatever respondent did in 1925 was, at most, "an abandoned experiment".

This finding was not disturbed by the Court of Appeals, although the defense was fully presented by respondent before that Court in its attack upon the validity of both patents.

We submit that the rule in *Adamson* v. *Gilliland* (p. 25, *ante*), is particularly applicable here since it is the defense to which the rule was applied in that case. To present all of the facts as to this defense would unduly lengthen this brief, but if the Court desires to examine the record to ascertain whether the undisturbed finding of the District Court was justified, we ask leave to submit a brief thereon.

X. Respondent's Argument (Br. pp. 47-53) that the Warth Patents in Suit Involve no Invention Over the Prior Art.

This defense is so foreign to any questions on which the grant of the writ herein was predicated, that we believe there is no reason for the Court to consider it. The defense was fully exploited in the lower Courts by respondent, and the District Court found against respondent, which finding was not disturbed by the Court of Appeals. The District Court's opinion (III, 1785-1787; 1789;

1790; 1797-1799) contains a full discussion of the prior art on which respondent relies.

If, however, this Court desires to examine this defense, we refer to a separate brief on it which we are filing herewith.

Conclusion.

It is submitted that, for the foregoing reasons, and those set forth in our main brief, the decision of the Court of Appeals below was in error, and that the Court of Appeals should be reversed and the case remanded to the District Court for the Eastern District of New York with instructions to enter a final decree holding both Warth patents valid and infringed.

Respectfully,

THOMAS G. HAIGHT,
GEORGE F. SCULL,
JOHN J. DARBY,
GEORGE W. PORTER,
Counsel for Plaintiff-Petitioner.

APPENDIX.

U. S. C., Title 35, Sec. 69 (R. S. Sec. 4920):

In any action for infringement the defendant may plead the general issue, and having given notice in writing to the plaintiff or his attorney thirty days before, may prove on trial any one or more of the following special matters: * * *.

Fifth. That it had been in public use or on sale in this country for more than two years before his application for a patent, *or had been abandoned to the public.*

Ex Parte **Replogle, 25 U. S. Pat. Q. 121, (Pat. Off. Board of Appeals—July 23, 1932):**

* * * The Examiner has rejected practically all of the claims under rejection on either or both of two former patents of appellant. The first patent is #1,345,550, patented July 6, 1920, and filed June 5, 1916. This patent shows a cleaner nozzle supported on casters having spring connected thereto fitted within pockets of the nozzle structure and these casters are so related to the mouth of the nozzle that air can pass by the casters and into the opposite ends of the nozzle mouth. The patent does not disclose the stroker elements nor the brush shown in the present application. Replogle Patent #1,541,280, issued June 9, 1925, filed August 1, 1924, discloses the spring supported caster as an independent element and the specification states it might be attached to hassocks, carpet sweepers or articles of furniture which are customarily subjected to sliding around the floor of living apartments.

Appellant has referred to a number of applications previously filed by him which are said to be a continuing series of applications all relating to various features of the suction cleaning apparatus. **Appellant relies upon this continuity of applications to overcome the two above referred to Replogle patents used by the Examiner as the principal references in the case.** Three of these applications are re-

ferred to more particularly. Appellant designates as case A the application which eventuated in patent #1,345,550 and as case B an application, Serial #279,467, which eventuated into patent #1,533,271. This latter application was filed February 26, 1919, and the patent issued April 14, 1925. This latter patent was issued just one month later than the date of the present application, case C, March 14, 1925. These two former applications form a continuing chain to the present application of certain common subject matter disclosed in them. The Examiner apparently concedes that the intermediate application, case B, discloses subject matter common to cases A and C. The Examiner holds that it is necessary for appellant to prove the presentation of a *continuing line of* **claims** *to the subject matter herein presented from a time just previous to July 6, 1922, to the filing of the present application.* This date, July 6, 1922, is fixed by two years publication of this subject matter by the granting of the Replogle patent #1,345,550 in July 6, 1920.

Appellant urges that such *claiming* is not necessary but only the presentation of the common subject matter in a continuing chain of applications and relies particularly to support his contention on the decisions in Folberth Auto Specialty Co. v. Mayo-Skinner Mfg. Co., 292 F. 893, and in Hartford Empire Co. v. Obear-Nester Glass Co., 39 F. (2d) 769. The first decision decided the question of two years do not run prior to the date of bar to a divisional application, when the two years do not run prior to the date of the parent application. In the latter decision, it was held that amendments of claims and filing of divisional applications is allowable more than two years after the original application is filed or after the last preceding divisional application is made, but if a stranger obtains a patent more than two years after the original application was filed, then applicant may not amend his original claims (so as to broaden them) nor file a divisional application embracing such claims after two years from date of patent to the stranger.

In accordance with these decisions an apparent statutory bar to the allowance of a divisional application to be effective **must also be a bar to the earlier parent application and a divisional application may be filed at any time,** provided a stranger does not claim the subject matter of the divisional claims in a patent more than two years prior to the assertion of such subject matter in the divisional case.

In the present situation, neither of the applications A, B and C are divisional of the other, but have common subject matter and are therefore continuations-in-part. There seems to be no doubt that appellant would obtain the benefit of the earliest filing date as a constructive reduction to practice of this common subject matter in an interference, Field v. Colman, 1913 C. D. 221. We believe that similarly appellant because of the continuity of applications A, B and C should not be held to be barred from claims to subject matter disclosed in all three.

In accordance with the doctrine announced in Mullen & Mullen, C. D. 1890-9, especially as to the third class of cases therein defined, there is no presumption of dedication to the public if claims to a separate invention are not presented after a patent showing but not claiming such invention was issued and there is no bar of two years' public use or sale nor actual abandonment. By the filing of application #427,088 which presented claims to the subject matter of the character presented on appeal, as well as application B, #279,467 (patent #1,533,271) **disclosing this subject matter but not claiming it, appellant refuted the presumption of dedication to the public of all subject matter not claimed in patent #1,345,550, and appellant having pending in this office in a continuing chain applications A, B and C which described the common subject matter and to which claims could have been directed at any time, we do not consider there is evidence of either abandonment of the subject matter, even though application #427,088 was abandoned, or of dedication to the public.** While the decisions referred to

above relate to divisional applications, we consider that even if the applications are not divisional, but contain common subject matter, that the apparent bar of two years publication should not be applied if it may not be applied to the earliest application in the chain of continuing applications disclosing common subject matter and there is no other evidence of abandonment or dedication to the public and no evidence of intervening rights of some other patentee. We note in this connection the decision in *Lee & Hogan* v. *Vreeland*, 317 O. G. 233. We hold that the rejection on the earlier Replogle patents #1,345,550 and #1,541,280 is not warranted. * * *

Patent Office Rule 46:

* * * In every original application the applicant must distinctly state under oath that to the best of his knowledge and belief the invention has not been in public use or on sale in the United States *for more* than two years prior to his application * * *.

Commissioner's Order No. 1832:

December 3, 1909.

When an application is found to be a division of one previously filed, the examiner will make an entry on the face of the file wrapper, in the place indicated thereon for such entry, of the serial number and filing date of the original application. The headline of the printed specification and the record of assignments will conform to this entry.

Commissioner's Order No. 2010.

October 18, 1912.

When an application is filed which *in the opinion of the examiner* is a division of, a continuation of, or a substitute for a previously filed application but which contains no reference in the specification to such prior application, the examiner will require the applicant to insert the proper reference to the prior application in the specification. If when the case is otherwise in condition for allowance, the request has not been complied with *or has been improperly made,* the proper reference to the prior application will be made by examiner's amendment and the case passed to issue forthwith.

No. 72

CROWN CORK & SEAL COMPANY, INC., *Plaintiff-Petitioner,*

v.

FERDINAND GUTMANN & COMPANY, *Defendant-Respondent.*

SUPPLEMENTAL REPLY BRIEF FOR PLAINTIFF-PETITIONER ON THE DEFENSE THE PATENTS IN SUIT DO NOT DISCLOSE INVENTIONS OVER THE PRIOR ART.

This brief is directed solely to respondent's defense that the two Warth method patents in suit are invalid because their disclosures are not inventions in view of the prior art (Resp. Br. p. 47-53).

Foreword.

For an understanding of the Warth patents and their relation to the prior art, it is necessary to appreciate the demand which arose for spot crowns before the inventions were made, the problems involved in the manufacture of spot crowns and the unsuccessful efforts made by skilled workers in the art to satisfy that demand over a period of

many years prior to Warth's successful solution of the problem.

While it is true that crown caps having center spots adhesively united to the cork were suggested in patents at least as early as 1914 (Demuth British Patent 16,075, III—1628), **that left the real and vital problem of cheap, i. e., high speed manufacture, wholly unsolved.**

Center spots for crown caps are particularly desirable for use with caps in which the cork disc is made of so-called "composition cork"; that is, small particles of cork held together by some form of adhesive binder. These composition discs are very much cheaper than discs cut from natural cork. But for many liquids composition cork is unsuitable, due to its tendency to disintegrate and to impart taste to some beverages (I, 354). The use of composition cork for crown caps was known at least as early as 1908 (Jones patent, III, 1634) and since an adhesively held center spot which would enable the use of a composition cork was known at a very early date, the remaining problem was to devise a method by which center spots could be applied to crown caps with composition cork discs (1) *accurately,* (2) *securely,* and (3) *at high speed* (I, 130).

In order to be successful the center spot must be accurately centered on the cork disc. If it is not, it may extend over the entire surface of the neck of the bottle at one side and thus permit leaking, and at the other side would permit the bottle contents to contact with the cork. (See the drawing opposite p. 2 of our Main Brief.)

Moreover, it is not sufficient merely to have the spot *loosely* adhering to the cork. It must closely adhere to the cork, particularly around the edge of the spot, so that it will not be dislodged in the hopper of the capping machine (I, 502), by which machine the caps are applied to the filled bottles at as high a rate as 160 per minute (I, 55).

Finally, it is vital that the spot crowns be made *cheaply,* i.e., *at high speed,* to meet the competition with other forms of corking.

By Warth's patented methods, petitioner is now applying these spots to crowns at the rate of *500 per minute* for each operating unit (I, 64).

Today, thanks to the inventions of the Warth patents in suit, spot crowns are made and sold in tremendous amounts and at a price which seems almost incredible. They sell at from 22 cents to 24 cents a gross (that is, about 6 for one cent), this cost including not merely the center spots, but the entire crown, consisting of the shell with its ornamental printing, the composition cork disc and the center spot (I, 58).

Petitioner's sales are at the annual rate of about nine million *gross* of center spots, which is about thirty per cent of its entire crown production.

Prior Attempts to Make Spot Crowns Commercially.

THE WHITE ROCK CROWN.

This crown, also known as the "Stewart," has been used by the White Rock Company since 1914 (I,) and is illustrated on Exhibit 17 (III, 1600). Only metal foil can be used for the spot, and this limits its use since metal is attacked by acidulated beverages such as gingerale.

The edge of a circular piece of foil is turned up to form a cup, this edge being inserted in a circular slit in the cork, the spot being held mechanically by this inserted edge, and not adhesively, to the cork.

The cutting of the slit necessitates the use of expensive natural cork since composition cork cannot be used.

This type is used only by the White Rock Company and possibly a few others. Though expensive, it is a commercial spot crown but it is entirely foreign to the adhesively-held spots involved in this suit.

THE "AMERICAN" TYPE OF SPOT CROWN.

This is also illustrated on Exhibit 17. Attempts to commercialize it failed and it is not now on the market. Instead of cork, the "cushion" was a rubber ring and the center

member, analogous to a center spot, was a cup-shaped piece of foil with the cup extending into the center of the rubber ring with its edges over the rubber ring, to hold the latter in place. The center of the cup was soldered to the metal of the shell of the cap.

Weisenburg attempted to make this "American" crown in 1916, but was unable to do so commercially (I, 60). Wagner, a former employee of the American Company, tells of its troubles with this crown (I, 427).

NEW PROCESS COMPANY'S UNSUCCESSFUL EFFORTS.

McManus, formerly president of the New Process Company, and now petitioner's president, a man highly skilled in the art and an inventor of standing, attempted to make center spot crowns commercially from 1915 to 1926 (I, 346). He used the facing material of his patent 1,213,926 (1118) and the machine of his patent 1,402,780 (1177). McManus tried paper center spots, with glue and gelatine as the adhesive, and tinfoil spots with an adhesive-coated paper between the foil and the cork (I, 343). He also tried (I, 345) the heat fusible cement mentioned in his patent 1,339,066 (I, 530) and which had been previously employed to unite the cork disc to the shell, but this also was unsuccessful.

In his commercial atempts, McManus used a water-soluble glue and moistened the surface of the cork before placing the glue side of the spot thereon. Though his machine centered the spot initially, a large percentage of them "floated" off center before the adhesive could dry, especially if the machine ran at any high rate of speed (I, 344). His limit was about 40 a minute and the method was costly. McManus' paper spots were parchment and this wrinkled (I, 345) permitting moisture to get through the paper to the cork, spoiling the contents and causing the spots to come off in the bottle (I, 345). The adhesive for the tinfoil spots was also water-soluble and they were subject to much the same manufacturing difficulties as paper.

In spite of double inspection to remove the "off-center" spots, McManus was obliged, in about 90% of the cases, to make adjustments for defective crowns (I, 344) and in the ten years from 1916 to 1926, he sent out no more than possibly 100,000 gross, most of which were tinfoil[1] (I, 346).

INTERNATIONAL COMPANY'S ATTEMPTS TO MAKE SPOT CROWNS.

Defendant's witness Alberti (I, 126, 131), and plaintiff's witness Marsa (I, 353-356) tell the story of the repeated efforts of the International Cork Company over a period of eleven years to manufacture spot crowns in which the center spot is adhesively united to the cork. Their experimenting began early in 1914, and continued until 1925 (I, 354) during which they expended from twenty-five to thirty thousand dollars (I, 356). They always used *wet, heat-set* albumen as the spot adhesive. Several machines were built, culminating in the machine of the Alberti patent 1,401,300 (III, 1449) which was finally abandoned (I, 182). Yet respondent relies upon this patent to anticipate the Warth invention. Alberti was unable to overcome the difficulties involved in producing at high speed which he says was essential for commercial production (I, 130). Clean and saleable spot crowns could not be produced by this machine. With insufficient glue, the spot would not adhere at its edges. With too much glue, bubbles formed at the edges.

The spots could not be accurately centered, and were always on "one side or the other, which would leave the cork exposed to the beverage" (I, 355).

The Alberti machine never left the experimental room and was run at only 40 to 50 caps per minute. Though carefully selected caps were submitted to customers, there were no orders and the experiment was abandoned after

[1] Nagy, for respondent, said (I, 141) that, when he worked for McManus' company in 1916, "It took about a week at that time to make 200 gross and the machine was working steady." Today, using the method of petitioner's patents, Nagy's machines have that output in about 2½ hours (I, 146).

a couple of years and the expenditure of several thousands of dollars. Respondent's witness Alberti says (I, 126) that "along in 1913, '14, '15 and '16", there were no successful center spot crowns except the White Rock, although repeated attempts to manufacture them were made by his company, International Cork Co., also by the New Process Cork Co., and by others.

JOHNSON'S EFFORTS.

Johnson's application for his improperly-issued patent (I, 583) was not filed until November 26, 1929. This was after he had been to petitioner's plant and observed the operation of Warth's method. Johnson had been an inventor and builder of assembling machines for thirty-three years (I, 160). He had been working since 1927 (I, 167) to develop a method for applying spots to crowns, yet as late as the Fall of 1928, after he had sent out unsatisfactory machines to Armstrong and to respondent (I, 213), he was still experimenting (I, 173).

PETITIONER'S DISCARDED SLIDE MACHINE.

This machine is referred to in the decision of the Court of Appeals and is described in our Main Brief (pp. 41, 43). Aside from the White Rock crown (p. 3, *ante*), practically the only commercial center spot crowns were manufactured in petitioner's plant by this machine and the steps employed are illustrated in the drawing opposite page 41 of our Main Brief. Although three of these machines were used for several years by petitioner, the method it employed made manufacture extremely slow and not more than *fifty* or *sixty* caps a minute were produced (I, 371). The method was a constant source of trouble for the reason that the disc did not always fall centrally in the slide and the spot would be picked from the slide so that it could not be properly deposited on the crown by the plunger which heated the spot before it was deposited (I, 371). Although peti-

tioner was constantly at work on the machine over a period of nine years, they never produced satisfactorily (I, 371).

The contrast between the Warth method and that of the slide machine is evident from the fact that by the Warth method the speed of production of petitioner's machine was increased to 420 per minute (I, 372). Subsequent improvement still further increased the speed to over 500 per minute, using the same Warth method.

The History of the Prior Art Shows that Although there was a Demand for Center Spot Crowns the Efforts to Produce them were only Failures.

Aside from petitioner's production of center spot crowns by its so-called "slide" machine, which production was small compared to its production after the introduction of the Warth method (II, 607), there was no manufacture of spot crowns having the center spots adhered to the cork. The efforts of McManus, Alberti, Johnson and others to produce a satisfactory method of manufacture shows the demand over a period of ten years (1915-1926) for a method which would satisfy the requirements of the industry, namely *high speed* production of crowns having the center spots *accurately* and *permanently* adhered. Weisenburg, who had been in the crown cap business since 1916 (I, 52) stated (I, 84) that although there seemed to be no great sale of spot crowns prior to 1927 or 1928,

> "there was a great need for them but we did not know how to make them."

Again, Marsa, formerly with the International Company, explained that their continued unsuccessful efforts to make spot crowns, were prompted by their "**feeling at that time * * * if we could get a thing like that we would make a killing with it.**"[1] (I, 354).

McManus also appreciated the demand for center spot crowns and this demand was the reason for his unsuccessful efforts from 1915 to 1926. He said (I, 346):

---

[1] Emphasis ours throughout unless otherwise stated.

> "I had always felt * * * that if anybody could develop a commercial center spot crown, there would be a very large market for it, and it would probably replace the large volume of natural cork that was done by Crown Cork & Seal Company at that time."

All of these prior attempts at "spotting" crowns were failures commercially and none solved the real problem of cheap (and therefore high-speed) production with accurate centering and close adherence of the spot to the crown.

The White Rock Crown was and is a success as a crown, but it is so expensive that, with the exception of one company, it has not gone into use, although all of the patents therein have expired long ago. The primary reason is that this type of center spot cannot be used with composition cork.

The American Company's attempt to solve the problem by using a complicated cap construction was a failure.

The attempts of International and McManus were either outright or practical failures.

While petitioner's slide machine method gave results of a sort, it certainly did not solve the problem of cheap production.

These attempts of large companies and highly skilled men over a long period of years and with ample capital to develop a satisfactory method to meet an obvious call for a spot crown, show that something more than mechanical skill was required to solve the problem.

The Warth invention is clearly of the class mentioned in *Paramount* v. *American,* 294 U. S. 464, in which the Court said (at 474):

> "Where the method or device satisfies an old and recognized want, invention is to be inferred, rather than the exercise of mechanical skill. For mere skill of the art would normally have been called into action by the generally known want. (Citing) *Loom Co.* v. *Higgins,* 105 U. S. 580, 591; *Krementz* v. *Cottle Co.,* 148 U. S. 556, 560; *Hobbs* v. *Beach,* 180 U. S. 383, 392; *Carnegie*

Steel Co. v. *Cambria Iron Co.*, 185 U. S. 403, 429, 430; *Expanded Metal Co.* v. *Bradford*, 214 U. S. 366, 381."

Warth's method is described in our Main Brief, pp. 4-6, and we will not repeat that description of it.

Warth's solution was based on his perception of how to overcome the trouble which arose primarily because of the speed with which the spotting must be done if there is to be cheapness of production.

To pick up a spot by hand and glue it to a crown in a laboratory way would not be more difficult than sticking a postage stamp on a letter. But when this is attempted mechanically, an intermittent operation results in which the crown to be spotted is moved step by step through the various operative stations. If the rate is even as low as 240 per minute, that means that each crown is started, moved to the next station and stopped in its new operative position, *all in one-fourth of a second.* This motion resolves itself into a series of short, sharp, rapidly-recurring jerks.

Yet in that split-second, the spot must be cut out and accurately centered in the cork and be stuck so firmly as not to be displaced when the crown is jerked to its next station.

With Warth's teaching now as part of our knowledge, it is now relatively easy to see why the prior art failed. For instance, it is now obvious that a wet adhesive will not do because, even if the spot is originally placed accurately on the crown, the wet and still slippery adhesive will not hold it there with such certainty as to prevent displacement as the crown is jerked along while the adhesive is drying. That was the trouble McManus and International experienced with their water soluble adhesives.

Again, it is now obvious that it will not do to punch out the spot at one point and then carry it to another point for application. The spots are small and wafer-thin and, if the rate is to be even 240 per minute, the impossibility of carrying the wafer from one point to another in one-quarter of a second is clearly going to be difficult, if not impossible.

Again, it is now obvious that a thermoplastic adhesive, like gutta percha, will not be slippery, like the wet adhesive, and will be a good adhesive if properly handled. But, because it becomes so "sticky" when heated, it must be handled so as not to receive its heat before the time of application to the cork.

Again, it is now obvious that the adhesive and the spot material should be made integral or unitary, by coating the adhesive on the strip material instead of using *separate* strips of spot material and gutta percha.

This, we can now see from Warth's teachings, will be accomplished:

(*1*) *if* the gutta percha is pre-coated in the strip of spot material before the spot is punched out, for then the spot will surely have adhesive over its entire area,

(*2*) *if* the adhesively coated spot is punched out just above the cork so that the punch will carry the spot immediately into its final position,

(*3*) *if* the heat is not applied to the adhesive until the spot is applied to and pressed on the cork; that is, in the language of the Warth patent, *upon or at the instant of assembly,* and

(*4*) *if* the spot is held under pressure while cooling.

The Prior Art Relied upon By Respondent Does Not Anticipate the Warth Method.

It is also now relatively easy to go back through the prior art and pick out one part of Warth's method from one place and another from another place. By combining these fragmentary disclosures, respondent attempts to anticipate the Warth patents.

But that is wisdom after the event and the courts have frequently condemned such piecemeal building-up of a successful invention from the prior art.

> "Where the thing patented is an entirety, consisting of a separate device or of a single combination of old

elements incapable of division or separate use, the respondent cannot make good the defense in question by proving that a part of the entire invention is found in one prior patent, printed publication, or machine, and another part in another, and so on indefinitely, and from the whole or any given number expect the court to determine the issue of novelty adversely to the complainant." *Parks* v. *Booth*, 102 U. S. 96, 104.

"It may be laid down as a general rule, though perhaps not an invariable one, that if a new combination and arrangement of known elements produce a new and beneficial result, never attained before, it is evidence of invention. It was certainly a new and useful result to make a loom produce fifty yards a day when it never before had produced more than forty; and we think that the combination of elements by which this was effected, even if those elements were separately known before, was invention sufficient to form the basis of a patent." *Loom Co.* v. *Higgins*, 105 U. S. 580, 591, 592.

The numerous workers in the art had the same suggestions before them and yet they did not see how such suggestions could be utilized to accomplish Warth's result. Otherwise, the art would not have waited for Warth's method which is now the one universally used for making spot crowns (I, 68).

Warth's alleged admission of lack of novelty.

Respondent refers to (Br. p. 50) to a statement in an abandoned Warth application (III, 1731), filed before the patents in suit, to the effect that "apparatus for cutting and assembling spot centers is known in the art." This we do not deny. Presumably, Warth was referring to the slide machine described in our Main Br. p. 41, and illustrated in the drawing opposite that page. Obviously, that machine has nothing to do with the methods of the patents in suit, and, therefore, the statement quoted from he Warth application is not an admission that apparatus for practicing the **methods of the patents in suit** was old prior to his invention.

Prior patents on cork disc assembly machines do not anticipate the Warth patents.

Respondent then refers (Br. p. 48) to a number of patents having to do with *machines for inserting cork discs in the metal shells.* These machines show various ways of adhering the cork disc to the shell.

Respondent's entire argument based on these "cork disc assembling machine" patents is based on the false premise that Warth's claimed method is merely the simultaneous application of heat and pressure and that heat and pressure may be applied at any suitable stage in the operation.

On the contrary, not only is the claimed method a complete one consisting of a *succession and combination* of steps, but it is further limited to the stage where the heat and pressure are applied *to the spot.* The drawing opposite page 5 of our Main Brief shows that the claimed method involves the following:

> *First,* a strip coated with thermoplastic adhesive is positioned beneath a punch and over a crown.
>
> *Second,* the punching operation is utilized to deposit the spot upon the crown in central position.
>
> *Third,* the heat and pressure are utilized or made available at the instant of assembly, or, as the claim states it, "upon assembly applying simultaneously" the heat and pressure.
>
> *Fourth,* the crown is cooled under pressure (claim 3, Main Br. p. 4— footnote).

While each of the steps is vital, as petitioner's witness puts it (I, 67):

> "This last (Third, *supra*) step of applying both heat and pressure instantly with assembling serves the useful purpose of positioning the center spot centrally in the cap and enables it to stay put until further operations can be performed. This must be done instantly. Where you are running a machine at 500 per minute there is no time to wait, and one must be sure that the spot is centally positioned.

"The use of heat and pressure instantly with deposit of the spot might be considered the keynote of the entire operation. However, the three steps are like, I might say, the three steps of a tripod. Without any one of the steps the method will not function."

Defendant's Argument of Want of Invention is Unsound.

Starting with its false premise referred to above, defendant claims to find the step of simultaneous application of heat and pressure in the very old art of assembling the cork discs in the metal shells in making non-spotted crowns, and then, from that, argues Warth's center-spotting method was obvious.

But that old cork disc assembling art differs essentially in its procedure.

(1) There was no problem of *centering* as there is in the spotting art, *since the cork disc fitted tightly* within the metal shell.

(2) Nor was there any punching operation, since the discs were preformed.

(3) Nor was there any necessity for the adhesive to cover the entire area of the two surfaces joined.

(4) Finally, and most important of all, there was no necessity for having the adhesive unite the two surfaces *at the instant they were brought together,* since the cork disc was not free to shift in the closely fitting shell.

Because of the simple requirements of the old art of inserting a cork disc in a shell, it was sufficient to drop some adhesive, either separately or on a paper disc, into the shell and then insert the cork disc. It was wholly immaterial whether the pressure was applied to the cork disc before, during, or after the heating of the adhesive *since there was no problem of centering the cork disc.* Each of these variants is shown in some of the patents on which defendant relies (Br. 48).

In contrast, when applying the *center spot* by the Warth method, it is essential (*1*) that the spot be punched out of

an adhesive-coated strip (*2*) that the punching operation be directly over the cork disc so that the spot will be placed immediately on the cork by the punch, (*3*) that the heat and pressure be applied to the adhesive on the spot *"upon" or at the instant of assembly* of the spot with the cork disc and (*4*) that the spot be held under pressure while cooling.

By this, the spot is not only correctly centered but it is positively adhered at the instant it is deposited. Since the spot is adhered in the Warth method at the instant it is deposited, it does not shift from position as the caps are rapidly stepped to the following positions for subsequent operations. When it is borne in mind that the crown shells are moved to and past the punching station, step by step at the rate of over 500 per minute, it is not difficult to appreciate the constant jarring of the shells which tends to dislodge and move the deposited spot.

By his method, Warth has solved the problem of *accurately centering* the spot and *permanently adhering* it, while at the same time permitting the *high speed manufacture* which is essential if the cap is to be manufactured commercially.

The best proof that nothing in the crown assembly art teaches the Warth method is to be found in the failures of prior inventors and workers, all of whom were familiar with cork disc and metal shell assembling machinery. Consequently, the practical history of the development of the Warth method, as shown by the inventors who sought unsuccessfully to provide an efficient method of manufacture, completely answers respondent's assertions that the Warth method is obvious from the prior art.

Respondent's arguments as to what skilled workers *might* deduce from the prior art is answered by the *fact* that those who sought to make use of this art failed in their efforts. Only Warth succeeded.

Respondent's Reference to Prior Patents on Center Spot Caps.

None of the spot crown patents cited by respondent (Br. pp. 48, 49) suggests a method of manufacture similar to Warth's.

The McManus patent 1,339,066 (I, 530) states:

> "Accuracy in the positioning of the disc *f* [center spot] in the commercial production of caps * * * may be secured mechanically in a number of different ways and by means of a variety of different mechanisms and the manner of assembling * * * is immaterial to the invention * * *"

As we have already shown (p. *ante*), when McManus sought to produce this cap commercially, he failed, although he had spent much time and money in his efforts.

Respondent's black lettered quotation from the McManus patent 1,339,066 (Br. p. 49) is grossly misleading, **since the quoted reference to the application of heat and pressure has nothing whatsoever to do with applying the spot to the crown.** The quotation refers only to the assembly of the *cork disc* with the shell and this involves no similar problems as we have shown. Moreover, the statement quoted from the McManus patent that in uniting a cork disc and shell, heat and pressure may be applied "simultaneously or successively" says nothing more than what is described in the assembly machine patents discussed pages 12-14 *ante*, and shows that in this procedure it is immaterial how or when the heat and pressure be applied. Yet respondent's use of the quotation would mislead the Court to believe that the patent there refers to a method of "spot" application.

Respondent's entire discussion of this and other patents infers that the Warth method consists simply in the step of using heat and pressure, regardless of how and when heat and pressure are applied. But we have shown that the Warth method is a *combination of steps*, involving among others the step of applying simultaneously heat and pres-

sure at the instant the spot is deposited. There is certainly nothing in any of the patents which respondent cites suggesting even this step alone or that it would be useful in center spotting.

Petitioner's Discarded "Slide" Machine Does Not Anticipate the Warth Patents.

Respondent finally refers (Br. 51) to the slide machine which was discarded upon the development of the Warth method. The operation of this machine is described in our main brief (p. 41) where we have inserted a drawing showing the successive steps followed in the use of that machine as to which the District Court found (III, 1790):

> "The combination of steps defined in the Warth methods of the patents in suit are not found in the plaintiff's first or slide machine, and it does not anticipate."

We have also shown in our main brief (pp. 41, 42) that the slide machine did not employ the combination of steps claimed in the Warth patents. Respondent seizes upon **one detail** of the operation of the slide machine, namely, the heated suction plunger by which the spot is lifted from the slide and heated *before* it is deposited on a crown and, because of this feature, argues that the slide machine is a complete anticipation of the entire Warth method. If the Warth method consisted merely in the use of heat and pressure, respondent's contention would be in point. But Warth's procedure involves much more than this as we have already shown.

The contemporaneous description of the slide machine (II, 613) from which respondent partially quotes (Res. Br. p. 52) explains the *entire operation* of the slide machine and shows that the *combination* or sequence of steps followed by that machine was essentially different from the combination of steps followed by Warth as we point out in our main brief (p. 42):

In the slide machine:

First. The spot was not formed from a strip coated with thermoplastic adhesive. On the contrary, *separate,* superimposed strips of metal foil and gutta percha were fed beneath a punch and the punching operation was used to unite the two separate discs formed as the punch descended.

Second. The punching operation did not deposit the spot (discs of foil and gutta percha) upon the crown. Instead, the punch deposited the discs in a slide which upon lifting of the punch, moved the two discs beneath the suction plunger.

Third. The adhesive (gutta percha) was not softened *upon or at the instant of assembly* of the spot with the crown. Instead, the gutta percha disc with the foil was rendered tacky while being held in raised position by the suction plunger.[1]

Fourth. The spotted crown was not held under pressure while cooling. Instead, it was discharged from the machine as soon as the plunger lifted.

Therefore, it is clear that the slide machine had in common with the method developed by Warth only the fact that a single element (suction plunger used to lift from the slide and heat the spot before it was deposited) applied pressure to the spot, as well as continued heat, when the spot was deposited

If the Warth method was obvious from the slide machine, as respondent asserts, it is strange indeed that petitioner struggled for nine years with that machine notwithstanding the evident demand for center spot crowns produced efficiently. Moreover, respondent's reliance on this machine

[1] As stated in the contemporaneous description (II, 613), "While the Tin Foil Spot and Tissue are being retained by the heater 'H' [heated suction plunger] the Gutta Percha Tissue is being heated; * * *".

to anticipate the method by which it was superseded as soon as Warth disclosed his invention to petitioner, completely overlooks the fact that the Warth method provided the solution to the problem of high speed production which the industry had been seeking to solve for the previous eleven years (pp. 4-6, *ante*). Disregarding everything else the fact that the Warth method enabled petitioner to increase its production for each operating unit from the maximum of *sixty* caps per minute, obtained with the slide machine, to over *five hundred* caps per minute, is of itself a complete answer to respondent's contention that what Warth did was not an invention over the slide machine.

The Warth patents do not cover a mere function of a machine.

Respondent also asserts (Br. p. 52) that the claims of the Warth patents are "for a mere function of a machine."

It is true that the methods are best practiced with a machine, but from this there is no reason for concluding that they are not methods within the meaning of the statute. The fact that a machine is used for practicing the method does not invalidate a patent on the method as such. This Court finally settled that question in *Expanded Metal Co.* v. *Bradford,* 214 U. S. 366. See also *Buffalo Forge Co.* v. *City of Buffalo,* 205 F. 83, 87, (C. C. A. 2) in which the Court said:

> "But that the means, and the only means of applying the process, are strictly mechanical is a matter of no moment, so far as patentability is concerned."

There are numerous cases in which method claims which refer to the use of a particular tool or instrumentality for practicing the method have been sustained. For example:

Michigan Carton Co. v. *Sutherland Paper Co.* (C. C. A. 6th), 29 F. (2d) 179.

The method of a claim in this latter case involved sealing cartons "by contacting with heated plates." The defendant contended that the claim distinguishes from the prior art processes only by including a "special form or arrangement of implement or apparatus"; but the court said (at 182).

> "The claim has nothing to do with 'implement' or 'apparatus' for bringing the plates into contact with the surfaces to be glued. This particular process could be performed by hand or by different mechanisms than those disclosed by the mechine claims. The disclosure is sufficient to enable any one skilled in the art to practice the process. It thus cannot be said that the claim involves 'nothing more than the operation of a piece of mechanism, or, in other words, for the function of a machine."

CONCLUSION.

The Warth patents clearly disclose inventions over the prior art and are valid.

Respectfully,

THOMAS G. HAIGHT,
GEORGE F. SCULL,
JOHN J. DARBY,
GEORGE W. PORTER,
Counsel for Plaintiff-Petitioner.

IN THE

Supreme Court of the United States

OCTOBER TERM 1937

No. 72

CROWN CORK & SEAL COMPANY, INC., *Plaintiff-Petitioner*,

v.

FERDINAND GUTMANN & COMPANY, *Defendant-Respondent*.

PETITIONER'S REPLY TO RESPONDENT'S SUPPLEMENTAL BRIEF

We would not file this brief except for the fact that respondent in its "supplemental brief" makes arguments which have never heretofore been made anywhere in this case.

Before answering these arguments, we make the simple comment that in final analysis the record shows that the Warth divisional patent was granted by the Patent Office in accordance with a practice which has existed for over fifty years.

It is a doctrine stated repeatedly[1] by this Court that a long-followed practice by a Governmental Department based on its interpretation of a statute will not be overthrown unless the statute clearly has been misinterpreted. This Court said in *United States* v. *Alabama Great Southern Railroad Company*, 142 U. S. 615, 622:

[1] See: *Bate Refrigerating Company* v. *Sulzberger*, 157 U. S. 1, 34; *Houghton* v. *Payne*, 194 U. S. 88, 99; *United States* v. *Graham*, 110 U. S. 219, 221.

> "It is a settled doctrine of this court that, in case of ambiguity, the judicial department will lean in favor of a construction given to a statute by the department charged with the execution of such statute, and if such construction be acted upon for a number of years, will look with disfavor upon any sudden change, whereby parties who have contracted with the government upon the faith of such construction may be prejudiced".

The above cited decisions apply particularly to the contention of respondent that public use (including the patentee's) more than two years before the filing date of a divisional application creates a statutory bar. The Patent Office has always interpreted the Statute (R. S. 4886—Main Brief p. 44) to apply only to an original[1] application and in *ex parte Halsey,* 1903 C. D. 41, 42, the Commissioner said that in an oath in a divisional application the "two years public use relates to the date of the original application."

Respondent's Argument (Supp. Br. pp. 3-7) that the Claims of the Divisional Patent Have No Foundation in the Original Application Disclosure.

As we understand respondent's argument, it is that one of the steps specified in the claims of the Warth divisional patent, was never disclosed by Warth until the divisional application was filed and that therefore the divisional application was not entitled to the filing date of the application for the parent Warth patent. Specifically, the alleged undisclosed step is defined in claims 2 and 3 of the divisional patent (Supp. Br. p. 5) as

> "then placing the linings in the caps under heat and pressure" (I, 557, claims 2 and 3).

---

[1] This Patent Office Rule 46 relating to the oath as to the statutory bars requires only that "In every *original* application the applicant must state under oath that * * * the invention has not been in public use or on sale in the United States for more than two years prior to his application etc."

This step is to be *subsequent* to the initial deposition of the linings (spots) by the punch and the simultaneous application of heat and pressure "at the instant of assembly" (I, 557).

As to claim 1 of the divisional patent, the implication of respondent's argument (Supp. Br. p. 6), is that that claim calls for "a cold cutting punch" which, as we show, is not true.

First taking up respondent's argument as to claims 2 and 3, we have the astonishing situation that respondent is arguing here now for the first time that the Patent Office gave the Warth divisional application the benefit of the filing date of the Warth original application for subject-matter not found in the latter. In other words, for the first time, after all of the briefing in the two lower Courts and here, respondent now presents a defense which, if true, would have been a complete defense as to claims 2 and 3.

But the defense is unfounded. As pointed out in our reply brief (p. 37 *et seq.*), the parent Warth application contains the following statement (III, 1246):

> "In carrying out the invention according to what is now considered the best practice the coating will be softened by heat *after* the crown is assembled. This may be accomplished in any suitable manner, as by a heated *plunger* or a plunger and heated table. The heat softens the coating and renders it adhesive and the pressure serves to unite the metal foil spot to the cork."

This quotation refers to the step in the method occurring at the station *following* the punching operation, at which latter station the spot has been punched out and applied to the cork with the simultaneous application of heat and pressure; that is to the "fourth step" in claims 2 and 3 of the Warth divisional application and which respondent *now* says was not disclosed in the Warth parent application. The quotation also refers to the use of a *plunger* and not to the punch.

As was also pointed out in our reply brief (p. 38), when the attention of the Patent Office was directed to the foregoing quotation in the Warth original disclosure (III, 1455), it agreed that the statement in the Warth parent application fully supported this "fourth step" and accordingly granted Warth claims 2 and 3.

Recognizing that its argument as to the "fourth step" of claims 2 and 3 could not, in any event, apply to *claim 1* of the divisional patent, since that claim does not specify this "fourth step", respondent (Supp. Br. p. 6) advances a different argument as to that claim. Respondent's argument that claim 1 has no support in the Warth original application, is that the original Warth application did not describe a "*cold* cutting punch." The answer is that claim 1 of the Warth divisional patent (I, 557) does not specify "a cold cutting punch," and, therefore, to support this claim it is immaterial whether the original application disclosure mention a "cold cutting punch."

In short, it simply is not true that Warth included in the description and claims of his application for the divisional patent any subject-matter which was not fully disclosed in the Warth original application for his parent patent.

The Failure of the Patent Office to Declare an Interference Between the Original Warth Application and the Johnson Patent.

Respondent (Supp. Br. p. 3) repeats its assertion that the original Warth application was not entitled to an interference with the Johnson application because, (Supp. Br. p. 7) when the Examiner was about to issue the *Johnson* patent and made his interference search thereon, Warth had no claims on file conflicting with Johnson's claims. As we pointed out in our reply brief (p. 20), respondent, in its main brief, completely missed our point as stated in our main brief (pp. 8-9). In its supplemental brief, respondent has *deliberately* closed its eyes to the evident fact (which it has not denied), that when the *Warth* original application

was ready for allowance and when the Examiner pursuant to the Patent Office practice made the so-called "interference search" as to the *Warth* application before passing it to patent, he should have found the allowed claim 35 in the Johnson then-pending application and should have declared an interference as to that claim between the Johnson application and the original Warth application.

That this claim (35) should have been the basis for an interference, is shown by the fact that after the Warth patent issued, the claim was then rejected in the Johnson application as "completely met [anticipated] in the * * * patent to Warth",[1] **thus showing that the Patent Office regarded the claim as fully supported by Warth's original application disclosure** and that it should have been the basis for an interference.

Consequently, even if it were true that at the time the *Johnson* patent was granted, Warth had no then-pending claims which conflicted with the Johnson claims, this does not answer our point that Warth *did* have both conflicting disclosure and claims on file when his original patent was allowed and that Johnson should not have obtained his patent without an interference with the original Warth application.

Respondent's Argument (Supp. Br. pp. 1-3) as to Abandoment.

Respondent does not deny that it failed to plead abandonment or to give notice of this defense before trial as the statute requires; see our reply brief p. 3.

As we understand respondent's argument, it is that, having argued abandonment *after* the trial and the District Court having rejected this argument, respondent should be permitted to continue to advance the same improper defense before all other courts. Petitioner has not waived its right to object to the presentation of the defense of abandonment. It had no opportunity to make such objection at the trial,

[1] II, 725—Official action of July 30, 1931.

because no such defense had been pleaded and no evidence was offered specifically to support such a defense. Respondent's urging of this defense has been wholly by way of argument based on evidence introduced at the trial to support other defenses.

There is no merit in respondent's attempt (Supp. Br. p. 2) to distinguish our citations showing the necessity for the pleading of the defense of abandonment. It is wholly immaterial what evidence is relied upon to establish abandonment. Regardless of the nature of the evidence, the statute requires that the defense be pleaded, as our cited cases show.

Respondent's Argument (Supp. Br. p. 8) as to the Warth-Johnson Interference.

There is no merit in respondent's purported answer to our citation of *Chillis* v. *Weisberg,* 1928 C. D. 24, to show that petitioner could not have elected, in the interference, to award the claims to Warth, as respondent contends should have been done under Patent Office Rule 94. As pointed out (*ante,* p. 3), the original Warth application fully disclosed the subject-matter of the method claims of the Johnson patent which Warth obtained as a result of the Warth-Johnson interference and that is all that is necessary here. It is wholly immaterial whether the Johnson application contained other disclosures which Warth's original application did not have.

Respondent's suggestion (Supp. Br. p. 8) that the assignment of the Johnson patent was not put *in escrow* pending the outcome of the Warth-Johnson interference, and that the Patent Office had no knowledge of the existence of such assignment at the time it was determined in that interference, is completely answered by undisputed direct testimony to the contrary (I, 335) and by the District Court's undisturbed finding (III, 1800, 1801) based thereon.

Respondent's Argument (Supp. Br. pp. 8-10) as to License.

We refer the Court to our reply brief (pp. 35-37) for the answer to practically everything that respondent argues upon this matter in its supplemental brief.

Respondent's argument really proceeds as if it were being sued here on the Johnson patent. Not only is petitioner not suing on the Johnson patent, but it is not relying here on anything which it acquired from Johnson or on anything to which Johnson could, by any possibility, have been entitled.

Respondent (Supp. Br. p. 9) asserts that, when petitioner purchased the Johnson patent, it granted Johnson "an *unrestricted* license to manufacture the apparatus of that patent." The evidence contradicts this assertion. In the first place, **the license to Johnson under the Johnson patent is not in evidence.** In the second place, Johnson himself (I, 170), testifying for respondent, stated that the license under his patent was *restricted* to the *future* sale of machines to those who had been licensed under petitioner's patents, which included, of course, the patents here in suit. In the third place, the license (II, 923) given to Johnson by petitioner under the *Warth* parent patent 1,788,260 limited such license to such sale of machines by Johnson as was authorized by the license to him under the Johnson patent (see license paragraph numbered 1; II, 923) and which license is not in evidence.

Finally, the license under the Warth parent patent specifically reserved (II, 924) petitioner's right to sue for previous infringement of the Warth parent patent by Johnson[1] and by those who had previously purchased machines from him, and it is clear that the machines which respon-

[1] The letter (II, 925) from petitioner to Johnson stated that petitioner would not sue Johnson as a contributory infringer of the Warth parent patent, but would sue those who were using machines previously purchased from Johnson. Respondent claims to be a user of such machines.

dent claims to have purchased were all acquired from Johnson before this license was granted.

Respondent's attempt to distinguish the facts here from those in the *Hartford-Empire* case cited in our reply brief (p. 36) is beside the point. First, respondent says that it is claiming under the statute (R. S. 4899, quoted footnote *infra*).[1]

It will be noted, however, that the statute is limited to machines purchased "prior to the application by the inventor * * * for a patent." We have shown in our reply brief (pp. 24-31) that respondent did not purchase from Johnson, prior to the filing of his application (November 26, 1929, II, 676), any machines using the preheating invention. Yet respondent's claim for a license is limited to the divisional patent covering preheating.

Moreover, the statute limits any license which might be obtained thereunder "to the specific thing so * * * purchased." Respondent is claiming a general license, not only for machines which it claims to have purchased before the Johnson application was filed (and which we have shown did not include the divisional patent invention), but also for machines purchased from Johnson in 1933 *after* the Johnson application was filed. Obviously, the statute does not apply to these.

Respondent's purported distinction of the facts here from those in the *Hartford* case is based entirely upon respondent's imaginative statement of the facts of the *Hartford* case. Respondent asserts (Supp. Br. p. 10) that, in that case, "an attempt was made to establish a license from Miller to the use of a feeder in which Miller had no legal rights." This statement, quoted from respondent's brief,

---

[1]Sec. 4899. (U. S. C., title 35 sec. 48.) Every person who purchases of the inventor or discoverer, or, with his knowledge and consent, constructs any newly invented or discovered machine, or other patentable article, *prior to the application by the inventor* or discoverer *for a patent*, or who sells or uses one so constructed, shall have the right to use, and vend to others to be used, *the specific thing* so made or purchased, without liability therefor.

is not correct, as the quotation from the *Hartford* decision in our reply brief (p. 36) plainly shows. The machines (feeders) which the defendant, Lamb Glass, in that case claimed to have a license to use were purchased from Miller who owned patents and applications thereon, which subsequently to the purchase of the machines, were assigned to the plaintiff, Hartford-Empire. The claim of license was based upon the purchase of these feeders and the transfer to *Hartford-Empire* of the Miller patents and applications covering them. Thus, it is clear that [redacted], in the present case, Johnson is in exactly the same position as Miller in the earlier case, that petitioner is in the same position as Hartford-Empire, and that respondent is in the same position as the defendant Lamb Glass of the earlier case. The facts, including the relations of the several parties, are alike in the two cases.

Respondent's Chapter (Supp. Br. pp. 10-11) on "Discussion of the Fact Testimony".

The first part of respondent's "discussion" purports to reply to our showing that it has not proved intervening rights (Our Reply Br. pp. 24-31). We do not understand respondent's assertion that "a fair reading" of the testimony of Cohn (I, 214) shows that what Cohn was saying "was that the machine in which he afterwards combined the spot and cork in one operation was the same kind as Exh. Q". It is clear from a reading of the testimony (I, 214) as well as the preceding testimony (I, 213) that Cohn there testified about the Exh. Q machines. Previously, he had referred to the Exh. P machine (I, 213, Q. 89). Then, he was asked (Q. 91, 92) as to the construction of the Exh. Q machines and it was of *these Exh. Q machines* that he said:

> "Yes, they had in addition to the mechanism for inserting the center spot, that was the same as on the previous *machine* [Exh. P], the mechanism for inserting

> cork discs into the metal shells after the manner of the Clark-Johnson type of assembling machines that had been used in the industry prior to that time".

In other words, he was identifying the 1928-1929 Exh. Q machines as machines which "combine the spot and cork in one operation", in the language of respondent's supplemental brief, and Cohn swore that those machines were not used until 1932 (our reply br. pp. 27-28).

Respondent asserts that the interrogatories (I, 144) show that respondent "had always used the preheating method shown by the Johnson patent." Even if the answers to the interrogatories were evidence, they do not support this assertion, as a mere reading of them shows. Moreover, if they did, they would not be true, since Johnson himself admitted that the machines sold respondent in July and August, 1928 did not have preheating.

The testimony referred to by respondent (Supp. Br. p. 11) as support for the assertion just discussed will be found to relate, first, to the rejected alleged prior use of the preheating invention by respondent in 1925 and which we have discussed in our reply brief (pp. 38, 39) and, second, (I, 281) to the machine to carry out the method of the Cohn patent which respondent's own evidence shows was not used prior to 1932.

The statements made by respondent (Supp. Br. p. 11) relative to the purchase by petitioner of machines from Johnson in 1929 are wholly without merit, as we point out in our reply brief (p. 32).

Obviously, Goebel's statement that the machines were "bought" from Johnson and that petitioner was "to pay the freight" thereon does not alter the fact that such machines were built by Johnson for petitioner and not for any one whose use of them could create an *adverse* right. Obviously, a machine must be "bought", even though it

be made specially for the purchaser and paid for under ordinary commercial terms.

Respectfully,

THOMAS G. HAIGHT,
GEORGE F. SCULL,
JOHN J. DARBY,
GEORGE W. PORTER,
Counsel for Plaintiff-Petitioner.

IN THE

Supreme Court of the United States

October Term, 1936.

CROWN CORK & SEAL COMPANY, INC.,
Petitioner,

vs.

FERDINAND GUTMANN & CO.,
Respondent.

Brief for Respondent.

The petition is for a writ of certiorari to the United States Circuit Court of Appeals for the Second Circuit to review an order entered by that Court in an ordinary patent suit involving the question of validity and infringement of six United States Letters Patent. An additional patent was set up by respondent as a counterclaim which was dismissed.

The decree of the District Court for the Eastern District of New York held two of the patents which were for Bottle Seals and one of which was for Strip Material for use in making Bottle Seals, invalid, and held one Bottle Seal patent and two patents for Method of Making such Bottle Seals valid and infringed.

No appeal was taken from the decision of the District Court as to the Strip Material patent.

The Circuit Court of Appeals affirmed the decision of the District Court as to the two Seal patents held invalid, and reversed that Court as to the validity of the other Seal patent and one of the Method patents, and as to infringement of the other Method patent, holding against infringement.

The petition seeks to review only that part of the decree of the Circuit Court of Appeals which held one of the method patents invalid and the other one not infringed.

The Circuit Court of Appeals denied a petition for rehearing.

The petition is opposed on the following grounds:

1. There is no conflict between different Circuit Courts of Appeals. This is the only suit ever adjudicated under any of the six patents upon which the suit was based.

2. None of the patents in suit is of any unusual or general interest. Therefore no public interest is involved in the suit.

3. There is no new point of law involved in the decision of the Circuit Court of Appeals.

4. The decision of the Circuit Court of Appeals is not in conflict with any doctrine established by this Court.

5. There is no important question of Federal law involved in the case which has not been, but which should be, settled by this Court.

6. There is no doctrine set forth in the decision of the Circuit Court of Appeals which is probably in conflict with applicable decisions of this Court.

7. While petitioner asserts that the Circuit Court of Appeals has not correctly applied decisions of this Court to the facts of this case, though at the same time arguing that important questions of Federal law are involved which have not been, but which should be, settled by this Court, such assertion is the usual one, made by every unsuccessful litigant finding himself aggrieved because of an adverse decision

by a Court, and does not constitute, "special and important reasons" for the granting of the writ of certiorari referred to in Rule 38-5 (b) of this Court.

8. An inspection of the decisions of both the lower Courts show that the real questions involved were the usual ones of validity and infringement.

9. As to one of the patents, the doctrine of laches, equitable estoppel and intervening rights applies, but the law applied to the facts by the Circuit Court of Appeals is well settled and in strict accordance with the principles of law laid down by decisions of this Court on somewhat analogous facts. As to the other method patent, the only question is that of infringement, which is a question of fact.

10. The petition and brief in support thereof contains many inaccuracies and omissions.

11. It is only by a partial and inaccurate statement of the facts shown by the entire record that petitioner is enabled to present even a plausible argument asking for the review of this Court, and the two so-called "questions presented" on page 9 of the Petition are not warranted by the Record.

12. A review of the record bearing upon the only two patents now in controversy shows conclusively that the questions petitioner seeks to review are purely questions of fact and not of law.

Argument.

The record is voluminous. As pointed out, six patents were originally involved, four for an article and the two patents in controversy for a method of making spot crowns. Three of the article patents were held invalid by the District Court and the fourth by the Circuit Court of Appeals.

In order to bring before this Court the salient facts upon which the Court of Appeals based its decision and correctly applied the principle of law laid down in *Webster Co.* v. *Splitdorf Co.*, 264 U. S. 463, and to show that there is no basis in the Record for the two questions presented on page 9 of the petition, it is necessary to refer somewhat at length to the record.

The two method patents in controversy and the state of the art as to the subject matter thereof.

The use of crown caps for bottling beverages and the necessity for using center spots are fully set forth in the decision of the Circuit Court of Appeals (p. 2146 Rec.) by Judge Swan who wrote the majority opinion. Judge Manton dissented therefrom, without opinion (p. 2155 Rec.)

The record shows that center spots have been cut from strip material and applied to an assembled crown cap by means of an interposed heat fusible adhesive by the application of heat and pressure since 1915 (p. 482-3 Rec.).

The two method patents involved, viz., Reissue 19,117 and 1,967,195 are each for a method of cutting the center spot from a strip of material either metal foil or paper coated with a heat fusible adhesive, and securing it to the cork disc by means of heat and pressure.

As previously stated the District Court found the patent to Warth 1,899,782 for strip material coated with a heat fusible adhesive invalid over the prior art (p. 2068 Rec.) Petitioner did not appeal from that decision (p. 2146 Rec.)

In order to have a center spot cut from a strip of material coated with a heat fusible adhesive, securely affixed to the cork disc, it is necessary to soften the adhesive by heating and apply pressure to make it adhere to the cork disc.

The patent to Warth Reissue 19,117 shows a method of supplying sufficient heat and pressure by means of a heated cutting punch which cuts out the center spot and sticks it to the cork disc by the simultaneous application of heat and

pressure. The claims are so limited, by the proceedings in the Patent Office and the action of the patentee.

The Warth Patent No. 1,967,195 describes and claims a method whereby the necessary heat is obtained by preliminarily heating the cork disc and then using a cold cutting punch to cut the spot from the strip of adhesive material and then applying pressure.

The record shows that a crown cap or metal shell containing a cork disc, secured to the metal shell by means of a heat fusible adhesive subjected to heat and pressure, were old as far back as the Painter patent of 1892, #468,226, page 4, lines 11, 108-128 (p. 1746 Rec.) Center spots secured to the cork disc by means of a heat fusible adhesive by the application of heat and pressure date back to 1915. Center spots per se were even older (Pats. to Demuth, pp. 1907-9; Nielsen 1,195,392, pp. 1927-8, Rec.). The use of plungers to cut and secure the spot was old. (Pat. to McManus 1, 402,780, p. 1421; Alberti 1,401,300, p. 1449 Rec.). The use of a metal foil or strip from which the spots were cut, coated with a heat fusible adhesive is concededly old. Petitioner so conceded when it failed to appeal from the decision of the District Court holding Warth patent #1,899,782 invalid over the art.

Warth, the patentee of both patents in controversy, filed an application for patent on "Bottle Caps" Aug. 21st, 1926 (five months before the filing of the original application for the patent 1,788,260 which is the parent case upon which the reissue is based). That application (which was abandoned) bore Serial No. 130,631 and as originally filed stated (p. 2015 Rec. Vol. 3.).

> "This paper disk is then secured to the cork disk by means of a backing 16 of some elastic and adhesive tissue, e. g. gutta percha, by means of a heated plunger or the like. By so applying heat and pressure to the assembled cork and paper disks the gutta percha or like backing is rendered adhesive and the paper spot is firm-

Italics ours unless otherwise stated.

ly cemented to the cork. *In this connection, it is noted that apparatus for cutting and assembling spot centers is known in the art.*"

The patent to Alberti #1,199,026, application filed October 2, 1914, states on page 2 lines 35 to 43 (p. 1267 Rec. Vol. 2)

> "The cementing medium is applied either to the exposed face of the sealing disk or packing of cork or the like, or it may be spread over that surface of the metallic disk that is to be in contact with the packing, or it may be carried by a layer of fibrous material that is to be interposed between the two disks," * * * the entire *closure being put, if necessary, under pressure and heated, whereby the cementing medium is coagulated, holding thus the metallic disk in place.*"

The patent to McManus #1,339,066, application filed November 17, 1915 states at lines 20 to 35 of page 2 (P. 695 Rec. Vol. 2) that the center spot is secured to the cork disc ordinarily by the use of a fusible binding medium interposed between the cap and the disc " and set in a manner to unite *the parts by the application of heat and pressure simultaneously or successively.*" The McManus patent was held invalid over the art by the Circuit Court of Appeals (p. 2149 Rec.).

The application for patent #1,967,195 became involved in interference with Johnson patent, No. 1,852,578 (Interference #66,201) discussed later, and the Examiner of Interference in a decision in that interference stated, page 868 (Vol. 2, fol. 2603):

> "Attention has been called to the patents to McManus #1,402,780 and Aberti 1,401,300, showing machines for this purpose. In these machines the caps are passed intermittently in single file beneath a reciprocating punch, which cuts the metal foil disk from a strip and deposits it upon the cork pad. *The caps then pass to an immediately adjacent heated plunger which applies sufficient heat and pressure to complete the union.* It was agreed by both parties at the hearing that machines of this character were used commercially prior to 1927 and that they operated at high speed."

The petitioner, on the trial of the cause, produced evidence to show that as early as 1915 it had a machine known as the "slide machine" for affixing the center spot to the cork disc (p. 482-4). A drawing of the machine (Ex. 43) was put in evidence by petitioner (p. 789 Rec.). A letter (Ex. 44, pp. 791-2 Rec. Vol. 2) from the head of the petitioner's engineering department states in part:

> "A Crown has now come into position under the Plunger and Heater 'H' which has moved into position relative to applying the spot to the crown. This is accomplished by the action of the pump 'B', which on its return stroke blows the spot from its position in the Heater on to the Crown which is *then pressed on to the cork in the crown by the Heater Plunger.* This completes the cycle of operations necessary for applying the Tin Foil Spot to the assembled #1 Crown."

The District Court, (p. 2081 Vol. 3 Rec.) in discussing that machine said

> "The *pressure of this heated punch* caused the gutta percha to stick to the cork and also to the foil spot."

There is therefore nothing new about the method claimed by either of the method patents in controversy.

Both of these patents should have been held invalid in view of the decision of this court in the case of *Altoona Theatres* vs. *Tri-Ergon Corp.*, 294 U. S. 477, page 486.

The District Court found the reissue patent 19,117 valid and infringed. The Circuit Court of Appeals held the patent not infringed.

The construction of the claims of the reissue 19,117 by the Court of Appeals was correct.

Counsel for petitioner (p. 16 and 26 brief) alleges the Court of Appeals erroneously construed the claims as limited to the heated plunger, and states in support of his argument the

decision of this court in the case of *Altoona* vs. *American Tri-Ergon,* 294 U. S. 477, 487. The argument is wholly without merit. In the case at bar the court of appeals very properly said (p. 2152 Rec.):

> "To read the claims of the reissue patent to mean a cold punch to cut the spots and a hot plunger applied later to fasten it to the cork disc would make them invalid under the old 'slide machine.' To read them to mean a cold punch which positions the spot upon a preheated cork would be inconsistent with the fact that the preheating specification was deliberately divided out later claimed in Warth's 'preheating patent' hereafter to be discussed."

Reference has already been made on page 7 of this brief to the slide machine used by petitioner beginning 1915. In addition reference is made to the other heat and pressure patents of the prior art discussed on pages 5-6 of the brief. If there is any novelty in reissue patent 19,117 over the disclosures of the prior art patents referred to, the claims, if valid at all must be limited to the precise method shown and described.

It is elementary that when a patentee acquiesces in the rejection of a claim during the progress of an application he cannot thereafter have a construction of the allowed claim which he accepted which will cover the matter he was forced to disclaim.

That law applies here with particular force. Warth voluntarily restricted himself, in his application 159,743 to the use of a heated plunger, and cannot two and one-half years after the cancelled matter has become public, claim a construction of the allowed claim to cover the cancelled matter.

The Altoona Theatres vs. *Tri-Ergon Corp.* case, relied upon by petitioner, shows page 487 that the finding of the Court of Appeals in that case was reversed by this court upon grounds which have no application to the facts in the case at bar.

Counsel for petitioner argues on pages 7 and 16 of his petition and brief in support thereof, that the Warth reissue patent 19,117 covers both methods of heating viz; heating the plunger and also preliminarily heating the cork before the spot is cut.

If he is correct in that contention then the second patent is necessarily void. There cannot be two patents for the same invention.

> *Miller* vs. *Eagle Mfg. Co.*, 151 U. S. page 186;
> *Underwood* v. *Gerber*, 149 U. S. 224;
> *Powder Co.* v. *Powder Works*, 98 U. S. 126 and 137.

It is true that the District Court held (pp. 2081-2 Rec.) that the Warth reissue patent covered both methods. The District Court also held (p. 2102 Rec.):

> "None of the claims of the divisional patent (1,967-195) is readable upon the disclosure of the reissue etc."

It is submitted that that finding of the District Court is clearly erroneous and inconsistent with its prior holding that the reissue patent covered both methods.

The Circuit Court of Appeals very properly reversed this holding and held that the Reissue patent 19,117 was restricted to the precise method of obtaining the necessary heat by heating the cutting plunger.

> *Hubbell* v. *U. S.*, 179 U. S. 77 at 83-4;
> *Leggett* v. *Avery*, 101 U. S. 256 at 259;
> *Kokomo Fence Machine Co.* v. *Kitselman*, 189 U. S. 8;
> *Weber Electric Co.* v. *Freeman*, 256 U. S. 668.

There is no proof of infringement of Reissue Patent No. 19,117.

The petitioner produced no evidence of any kind at the trial to show that respondent infringed the claims of the

reissue patent calling for the simultaneous application of heat and pressure at the time of assembly.

The only evidence of infringement of either patent shows that the petitioner's officers and counsel called at the respondent's factory August 8, 1933 (pp. 301 and 683 Rec.) for the purpose of discussing a settlement and were shown respondent's method being used by respondent at that time, which was the method of the Johnson patent 1,852,578 as modified by the procedure called for by Cohn patent #1,921,808 which also called for preheating the cork disc and used a cold cutting punch. That Cohn patent was the subject of respondent's counterclaim. The method claims of said Johnson patent are now the method claims of #1,967,195 viz., preheating the cork and applying the center spot by a cold punch.

The only evidence as to the method used by respondent was that given by respondent's superintendent and manager, both of whom emphatically stated that the respondent had always preheated the cork disc and never had used a hot cutting punch. *It had always used a cold cutting punch only* (pp. 287 & 375-6, Rec.).

The testimony of the witnesses for respondent Benno Cohn and Chas. Rasmussen, was to the effect that, beginning in December 1924 and ending in March 1925, the respondent had made and sold to the Inecto Company upwards of 300,000 caps having metal foil center spots secured to the cork disc by means of gutta percha which is a heat fusible adhesive by the application of heat and pressure.

The testimony of these witnesses shows that the method respondent used was as follows:

In December 1924 and January 1925 it used an old Clark-Johnson assembling machine (a machine for assembling the cork disc in the metal crown without a center spot) put a center spot cutting attachment thereon and preheated the cork by means of gas jets adjacent a chute which carried the assembled crowns to the spotting attachment where the center spots were secured to the cork disc by heat and subsequent cold pressure. That testimony on its face invalidates both

of the method patents now under review because (if reissue 19117 is to be so construed as to include preheating the cork disc) respondent used this method more than two years before the filing of the application for either method patent.

The testimony of these two witnesses was substantiated by officers of the Inecto Company who not only recollected that the caps were so made, but identified invoices rendered by respondent to that company and produced correspondence showing beyond all question that respondent made and sold the caps to that company on the dates mentioned. Only 300,000 were made and then discontinued because the Inecto Company sold a hair tonic having an ingredient which it was afraid might be deleteriously affected by the gutta percha, and it decided to use a cap with a flanged metal center spot forced into the cork disc as disclosed by Patent to Nielsen 1,195,392 (p. 1921 Rec.). It was further substantiated by people who sold the gutta percha and tin foil strips to responded (pp. 211-13; 256-7 & Exs. H to O & NN to TT, pp. 1170-86 Rec.).

The District Court disregarded the testimony of Cohn and Rassmussen as to the method, stating in its opinion (pp. 2078-9) that it believed they were honestly mistaken and there was not sufficient corroboration of the method either by the production of the original machine nor of any caps alleged to have been made at that time.

The District Court, however, found as a matter of fact that the respondent did make the caps at the dates mentioned and stated that "it was known to the art" (p. 2067 Rec.).

The Circuit Court of Appeals, with this evidence before it, made no specific finding either way on the question of this prior use. It did, however, accept it to the extent that it held that the method used by defendant was that of a cold plunger and therefore did not infringe the claims of the Reissue Patent No. 19,117 which are restricted to the method of applying the heat and pressure simultaneously to the cork disc when the center spot is cut out by means of a heated plunger.

Neither party uses a heated cutting punch as called for by Reissue Patent 19,117. It has been pointed out that respond-

ent always used a cold cutting punch (p. 10 of this brief). The petitioner's own witnesses said that it did not between 1930 and 1934 use a heated cutting punch (p. 134 Rec.) and the District Court so found (p. 2081 Rec.).

There is thus a finding of fact by the Circuit Court of Appeals based on adequate evidence and upon the only construction that could be made of the claims of Re-issue patent No. 19,117. It is submitted that certiorari should not be granted to review solely that question of fact. That it is the well settled practice of this court not to review questions of fact on Certiorari is demonstrated by the case of *Maytag Company* vs. *Brooklyn Edison Co., Inc.* page VIII, No. 654 where the Court of Appeals reversed the District Court on the question of validity and the case of *United Chromium, Inc.* vs. *General Motors Corp.*, page XI, No. 733, where the Circuit Court of Appeals reversed the District Court on the question of priority of invention and *Perey Mfg. Co. Inc., et al.* v. *Tulchen,* XI No. 746, where the Circuit Court of Appeals reversed the District Court on the question of infringement. 299 U. S. (Advance sheets).

The subject matter of the claims in Warth patent 1,967,195 was completely and voluntarily dedicated to the public by Warth.

The record shows that when the Warth application for a method of applying a center spot to crown caps by heat and pressure was applied for on January 7th, 1927, Serial No. 159,743, the use of a heated plunger was disclosed (p. 1490 Rec.) It also contained the following statement:

> "It may be desirable to secure the metal foil spot in position prior to the heat and pressure steps, sufficiently to prevent dislodgement of the spot during any interval between assembling and final sticking. This may be accomplished, for example, by preheating the assembled crown to soften the coating as soon as the metal foil spot is deposited. Or the coating may be softened by moistening slightly with a solvent, such as benzol. In

> either case the coating becomes tacky enough to hold the metal foil spot from getting out of position during ordinary passage through assembling apparatus."

It originally had claims for a method including coating metal foil with an adhesive rendered soft by heat and applying heat and pressure by means of a heated plunger and or by preliminarily heating the cork. It also had two product claims for an adhesive, which were cancelled on a requirement for division. All the method claims were rejected in an Office letter dated January 11th, 1929 (p. 1497 Rec.) The Office letter stated that the method claims were "rejected on any of the references cited which disclose the coating of a metallic foil with an adhesive which is rendered soft by heat, applying the coated metal to cork and holding under pressure until the adhesive hardens." That letter also required a drawing if any claims were subsequently found allowable. The case was amended (p. 1498 Rec.) by cancelling claims 1, 4 and 6 and limiting one of the claims by inserting "cutting a facing spot from coated foil". The amendment stated (p. 1499 Rec.):

> "The Examiner states that any of the references discloses the use of an adhesive rendered soft by heat and applying under pressure. But applicant is not claiming anything so broad as that."

The case was then finally rejected, and an appeal taken (pp. 1500-1 Rec.) Attention is called to the Examiner's statement (pp. 1502-3 Rec.) It will be noted the Patent Office, in its rejections made no distinction between the two methods by one of which the heat was applied to the cutting plunger and the other for preliminarily heating the cork, but rejected both methods. On December 3rd, 1930, after an interview with the Examiner (p. 1508 Rec.) all the claims were cancelled. The application being almost entirely rewritten (pp. 1509 to 1518), the claims all cancelled and one specific claim inserted, limiting the method to "upon assembly applying

simultaneously to the spot, pressure and sufficient heat to render the adhesive tacky."

It will be noted that the amendment also voluntarily cancelled the matter we have quoted at page 12 brief, supra as to the pre-heating of the assembled crown. With the amendment a drawing was filed showing a heated plunger. After an amendment under rule 78 was made inserting another claim, which was the same as the one claim allowed with the exception that it was limited to a metal foil spot (pp. 1530-1 Rec.) the application was allowed and the patent was issued on January 6th, 1931, bearing number 1,788,260 (the parent of the reissue 19,117). The issued patent 1,788,260 had no disclosure of and made no reference to preliminarily heating the cork.

Obviously, when the patent issued it was open to the public and any member of the public interested in the patent could look at the Patent Office file history and see that the patentee had abandoned and dedicated to the public, both the subject matter and the claims for the method of obtaining the necessary heat by preheating the cork. There can be no clearer case of voluntary dedication to the public of this method than the action of the patentee in this instance.

Patent 1,967,195 contains the statement that the original application was filed on November 7, 1930, Serial No. 494,201, which in turn is a division of Serial 159,743, January 7, 1927, now patent 1,788,260, dated Jan. 6th, 1931.

It is true that Serial No. 494,201 filed on November 30th does contain the disclosure as to preliminary heating the cork which was cancelled from the parent application of January 7th, 1927, #159,743. The District Court held, and petitioner argues, that because an application containing a disclosure of the method in connection with an entirely different invention, but making no claims to the method per se, or any method of any kind, was in the Patent Office at the time of filing the application of April 4th, 1933, which resulted in patent 1,967,195, the patentee Warth was entitled

to the date of January 7th 1927 when he first filed an application claiming that disclosure.

There are two complete answers to that erroneous holding of the District Court and the contention of petitioner in attempting to uphold it. The first answer is that, as above pointed out, when the parent patent 1,788,260 issued and became public on Jan. 6th 1931, the file shows that the preheating method and claims therefor had been abandoned and the patentee had elected to take claims for the narrow and specific method of applying heat to the plunger.

The second answer is that the application Serial No. 494,201 was for an entirely different invention. It is not an application for a patent on a method at all. The application 494,201 (p. 1948 Rec.) states that it is for an improvement in "Bottle Cap Spot Material". It appears from the specification (p. 1950-2 Rec.) that the alleged invention consisted of coating a strip of tin foil or aluminum foil with a heat fusible adhesive. There was one claim which read in part

> "As a new article of manufacture, highly flexible laminated material in sheet or strip form for the spotting of cushion disks, etc."

The claim was rejected as obviously met by a number of prior art patents, (pp. 1955-6 Rec.) and the Office action said

> "This case appears devoid of invention and should be prepared for a final action."

The case was amended and a drawing inserted showing the method of putting the adhesive on the strip material.

The drawing also showed and the amendment stated (p. 1964 Rec.) that the heat for softening the material was to be attained by maintaining the cutting punch 20 at an elevated temperature. The drawing so far as the heating method is concerned was the same as that shown in reissue 19,117.

On pages 1968-9 Record ten advantages were enumerated for the invention, most of which were to show the great desirability of applying the adhesive by coating it on the

strip material instead of feeding a separate sheet of cap material and a separate sheet of gutta percha tissue as had previously been done. The tenth advantage claimed (p. 1969 Rec.) was

> "The heat and pressure necessary for uniting the facing to the cap may be applied substantially simultaneously with the punching and assembly operations, etc."

The case was again rejected, (p. 1972) the office letter stating that it should be prepared for final action. It will thus be seen that in application 494,201 which is relied upon by petitioner to show that the matter was still before the Patent Office, the applicant again illustrated and described *the heated plunger. He did not urge or mention the desirability of preheating the cork.*

It is further significant that the applicant in an amendment (p. 1969 Rec.) dated June 16, 1931, after patent 1,788,260 had issued on Jan. 6, 1931 for the method, stated:

> "As a further feature of the invention, the applicant proceeded to provide a method involving the use of this article. However, the article is the basis for the method. Protection having been granted for the method, it is thought that the same argument which supports the patentability of the method, applies with much greater force to the article, without which the method could not have been provided."

The claims were again rejected (p. 1972). Thereafter, amendments were made with other claims and finally the application was allowed on Feb. 1st 1933 (p. 1984 Rec.) with two claims. One of the claims was cancelled and transferred to the application for such strip material patent 1,899,782 held invalid by the District Court. The case was allowed to lapse for non-payment of fee and was renewed on Feb. 1st 1934 with other claims put in and it was again allowed on Oct. 5, 1934 (p. 2000 Rec.) but the patent was never issued and counsel for respondent on February 14th 1935, had to apply to the Commissioner to obtain a copy of the application and the re-

quest was acquiesced in by counsel for petitioner (pp. 2005-6 Rec.).

When the Johnson patent was ready for issue there was no application pending in the United States Patent Office containing claims conflicting with the method claims of the application for that patent, No. 1,852,578.

When Warth filed the application on April 4th 1933 for the patent which resulted in #1,976,195, his attorneys wrote a letter to the Patent Office stating that (p. 1686 Rec.):

> "It is to be noted that the issued patent (1,788,260 on which the reissue was founded) does not disclose the preheating of the crown or pad within the crown."

Despite that statement, petitioner now asserts in this Court, that reissue of Patent No. 1,788,260 embraces the very feature admitted not to be disclosed in that patent or reissue, and asks that the claims be construed to cover a feature not disclosed in the patent, and which was deliberately cancelled from the application therefor.

Directoplate v. *Donaldson Lith. Co.*, 51 F. R. (2) 199;

Rosenberg et al v. *Carr Fastener Co.*, 51 F. R. (2) 1014 Cert. Denied 284 U. S. 652.

A divisional application cannot be obtained after the Parent case issues. They must be co-pending.

The assertion by petitioner on pages 3 and 5 of the petition that the decision of the Circuit Court of Appeals for the 2nd Circuit, in this case, reverses the accepted practice in the Patent Office, is not warranted. That practice is clearly defined in the case of *Fessenden* vs. *Wilson et al.*, 48 F. R. (2d) 422, (Ct. Cust. & Pat. App.) where the Court said at page 424:

> "We agree with the Board's finding as follows: 'Fessenden's earlier application became a patent May 14,

> 1918, and the patent contained no disclosure of the invention claimed in Fessenden's later application. There was an interim of more than three years between the grant of the patent upon the earlier application and the filing of the later application. The later application cannot have the benefit of the date of the earlier application as a continuation thereof. The proceeding relating to the two must be in fact continuous. Sarfert v. Meyer, 1902 C. D. 30. An application cannot be considered as a continuance of a patent granted prior to the filing thereof, since after the application has eventuated into a patent there is nothing left pending before the Patent Office upon which it could act or to which the later application could attach. In re Spitteler, 31 App. D. C. 271, 134 O. G. 1301; Wainwright v. Parker, 32 Add. D. C. 431, 142 O. G. 1115, 1909 C. D. 379."

The facts in the case quoted from are exactly like those in the case at bar. Warth's original patent 1,788,260 on which the reissue was founded, as previously pointed out, issued in 1931, with no disclosure or claims for the method of 1,967,195. The fact that the disclosure was still in the Patent Office in Serial No. 494,201 in no way affects the applicability of the law laid down in the cited case. Application 494,201 was for an entirely different invention, and no method of any kind was ever claimed in that application. When the original of the reissue issued an inspection of the file wrapper showed that the disclosure and claims for the method of preheating the cork was voluntarily cancelled from the application and the public had notice thereof.

The application upon which the Warth Patent 1,967,195 was granted could not be a division of application Serial No. 494,201 or 159,743 because the subject matter of application for patent 1,967,195 was voluntarily cancelled and abandoned in 159,743, and any assertion of a right to a patent upon the cancelled subject matter was not made until the filing of the application for Patent No. 1,967,195 more than two years after the issuance of Patent No. 1,788,260 granted upon application Serial No. 159,743. While such claims might have

been asserted at any time during the pendency of application Serial No. 159,743, they could not be asserted after the issuance of Patent No. 1,788,260, even by reissue and much less so by divisional application, because of abandonment of record of the subject matter.

If Reissue 19,117 is entitled to a construction of a scope to include preheating the cork disc as called for in patent 1,967,195, to sustain patent #1,967,195 would be to extend the monopoly. *Saranac Automatic Machine Co.* vs. *Wirebounds Patents Co. et al.*, 65 F. R. (2d) 904 (C. C. A. 6th) at 906, where the court refers to the prior decision of this Court in another case, involving the same patents reported in 282 U. S. 704 (see pp. 714-15).

In order for patent 1,967,195 to be entitled to the date of Jan. 7, 1927 (the application date of the original of the reissue) the application for 1,967,195 would have to be filed before the issue of the first patent.

Gen. Motors Corporation v. *Rubsam Corporation*, 65 F. R. (2) 217 at 220 (C. C. A. 6);
In re Nathan, 279 F. R. 925.

The record shows a clear case of intervening rights.

Counsel for petitioner states in his petition and brief in support thereof (pp. 3, 17, 19) that there were no intervening rights other than the issue of the Johnson patent and the admitted use by petitioner in 1929 and calls attention to the fact that the District Court ignored respondent's use of the method patent 1,967,195 and that there is no express finding of the Court of Appeals to the contrary. Petitioner therefore argues that the doctrine of *Chapman* vs. *Wintroath* applies, because Warth, when he filed his application for 1,967,195 copied the claims of the Johnson patent within two years from the issuance thereof and thus comes within the principle of *Chapman* v. *Wintroath*.

While it is true the Ciruit Court of Appeals made no specific finding on the question of intervening rights, it is very apparent that in applying the doctrine of *Webster* vs. *Splitdorf,* it based its decision on the facts in the record and necessarily found as a fact that there were intervening rights, without specifically saying so, otherwise it would not have reversed the District Court and applied the doctrine of *Webster* vs. *Splitdorf.* Obviously the Circuit Court of Appeals always goes into the facts in a patent case de novo.

Owing to the misleading statement by Petitioner on page 9 of his petition and brief, "Even in the absence of intervening adverse rights" it is necessary to briefly refer to so much of the record as shows that respondent, from 1928 up to the time of the trial, used the method of preheating the cork as claimed in the Warth patent 1,967,195.

Respondent bought its machines for center spotting caps from Johnson, beginning as early as July 1928 and ending in the Spring of 1933. The petitioner endeavored to show in the trial court that the first machine purchased by respondent from Johnson in 1928 did not have a device for preheating the cork and the District Court found that none of the machines purchased by respondent from Johnson had a preheater (p. 2100 Rec.).

There was conflicting evidence as to whether the first two machines bought by respondent from Johnson in July and August of 1928 had or had not the preheating device. We may assume for present purposes that they did not. It is proved, however, beyond all question, that the additional machines purchased by respondent from Johnson in September 1928, December 1928, March 30, 1929 and April 30th 1929 did have a preheating device for the reason that respondent's Exhibit Q (pp. 1102-3 Rec.) shows that each one of the bills to repondent from Johnson call for a number of features among which is "a roll feed etc.". The roll feed means "a spotting" attachment (p. 350 Rec.). The bills of Johnson for the July and August machines (Exhibits P

and S, pp. 1101 and 1108 Rec.) each call for one tin foil machine etc. Subsequently and between May 5th and June 19th 1933, respondent purchased four other machines from Johnson (Exhibit R, pp. 1104-7 Rec.). The center spotting machines were purchased from Johnson by respondent for the purpose of manufacturing center spot crowns having a metallic foil spot secured by gutta percha to meet a large commercial demand which arose about that time for center spots by brewers. Respondent received inquiries, and ultimately orders from the Goetz Brewery, one of the largest breweries in the country, for the production of crown caps for beer bottles with a center spot of metal foil (pp. 268-278 Rec.).

Mr. Ketterer, manager of the Goetz Brewery, a witness for respondent identified invoices for crown caps having a metal center spot, which respondent's witnesses said were made on Johnson center spot machines having the preheating device and secured by gutta percha, running continuously from August 1928 until November 1935 aggregating approximately one million gross of caps to that one customer. (Exs. NNN to TTT pp. 1763 to 1812.) In addition to that one customer, respondent sold a great number of center spot crowns made by a method including preheating the cork disc before the center spot was applied, to other customers. In 1930 and 1931 it sold carloads of crowns made by that method to the Welch Grape Juice Co. (pp. 318-19 Rec.).

That the spotting machines made and sold by Johnson to respondent the latter part of 1928 and in 1929 and 1930 had the preheating device is conclusively shown by the cross examination of Johnson by petitioner's counsel, at pages 237-8 of the Record, from which it appears that Johnson put the preheaters on the machine he had sold to Armstrong, on October 5th 1928. He said in answer to XQ 116:

> "I took the heat out of the cutting punch altogether and installed two heaters in front of it, and also a space heater I installed before the tin foil disc was cut and inserted. *And that kept the cutting punch cold.*"

In part of his answer to XQ 113 he said:

> "And I put preheaters on it, and took out the heater in the cutting punch and heated the cork before the spot was inserted * * *."

That petitioner had actual knowledge of the use of machines for carrying out the method of preliminarily heating the cork covered by the claims of method patent 1,967,195 by respondent and others, is conclusively shown by its own act in copying the three method claims of the Johnson patent for the purpose of interference (p. 1686 R.) and the evidence adduced during the interference.

The issue of the interference was, of course, the three method claims of the Johnson patent, now the only claims of patent 1,967,195. A copy of Warth's preliminary statement does not appear in the record. A copy of the preliminary statement of Johnson is found on pages 2043-4 of the record, from which it appears that he constructed a full sized apparatus for carrying out the invention during the fall of 1927 and sixteen apparatus for carrying out the invention of the issue had been constructed.

When Warth got into interference he, of course, knew that he had to go back of Johnson's filing date of November 26th 1929 and Warth therefore alleged as reduction to practice the date of his application Serial No. 159,743, for the patent resulting in 1,788,260, the parent of reissue 19,117. As has been pointed out, the step of preheating the cork, shown in 159,743 was cancelled from that application on December 3, 1930.

At the beginning of the interference Warth made a motion to shift the burden of proof in an effort to obtain the date of filing of 159,743, viz Jan. 7th, 1927. The motion was denied by the Examiner of Interferences on the ground that the Jan. 1927 application of Warth did not contain a disclosure sufficient to support the counts (pp. 438-9 Rec.). Johnson also filed a Public Use Proceeding from which it appeared that machines for carrying out the method of his patent were

made and sold and in public use more than two years prior to April 4th 1933, (when Warth filed the application for patent 1,967,195) by several persons, among whom was the respondent, the Arrow Bottle Cap Corp. of Brooklyn and the Crown Cork & Seal Co. Inc., the petitioner herein (p. 1130 Rec.). Johnson's petition for Public Use Proceedings was corroborated by a number of affidavits found at pages 1133 to 1148 Rec.

After the decision of the Examiner of Interferences denying Warth's motion to shift the burden of proof, the Petitioner on December 12th, 1933, purchased the Johnson patent and took an assignment thereof (pp. 226, 1162 Rec.). The assignment was never recorded (p. 610 Rec.). After the purchase by petitioner of the Johnson patent the interference was still continued and a stipulated record consisting of affidavits made by Warth and two others was made up for the purpose of final hearing and appeal (p. 1890 Rec.). On that stipulated record the Examiner of Interferences reversed his prior decision and awarded priority to Warth. Counsel for Johnson filed no brief at final hearing (p. 576 Rec.). All papers filed by Johnson in the public use proceeding were withdrawn from the Patent Office by petitioner after petitioner purchased the patent from Johnson (pp. 227-9 Rec.).

Defendant's Exhibit T (1109 to 1120), shows bills running between March 1929 to July 31, 1929 for five tin foil spotting machines sold and delivered by Johnson to Petitioner. One invoice calls for "foil cutting dies for tin foil machine." Attention is called to page 1112, which shows a letter dated Feb. 27, 1929 from petitioner to Johnson stating:

> "Referring to your conversation and correspondence with our Dr. Warth, would suggest that you send us on approval the machine for adhering the gutta percha lining to the tin foil. Also the machine for cutting the tin foil and fastening the same to the cork washer on finished crowns."

The petitioner's vice president, Fusting, and its superintendent Goebel admitted the purchase of these machines

at the times mentioned (p. 683 Rec.). They said they were purchased for their Canadian plant. Nevertheless the Invoices show and both of the witnesses above mentioned admitted, that the machines were shipped from Johnson's plant in Brooklyn to petitioner's plant in Baltimore, Maryland. That the machines were there "tuned up" for shipment to the Canadian plant (p. 554 Rec.). Petitioner's own act in buying these Johnson machines inspecting them and sending them to Canada (if it did send them to Canada) shows public use by Petitioner itself, slightly more than four years before Warth filed his application for patent No. 1,967,195, on April 4, 1933. When it is considered that respondent sold caps made by the method covered by the method claims of the Johnson patent (which are now the only claims in Warth patent 1,967,195) in large quantities to various customers continuously from 1928 up to and including the time of trial, and that Johnson's public use petition shows the manufacture and sale of machines made and designed for carrying out the method of the claims under discussion, which petition is corroborated not only by the accompanying affidavits but the admitted purchase by petitioner of such machines in 1929, it is submitted that there can be no clearer case of public use and intervening rights than is shown by the record of this case. No question was raised by petitioner's witnesses as to the fact that the five machines shipped to it by Johnson to Baltimore had the means for preheating the cork. The letter to Warth dated February 27th, 1929 (p. 23, *supra*), asking that machines be sent on approval completely negatives any possibility of that question being raised. Furthermore it is negatived by Johnson's testimony on cross examination referred to on pages 21-22, *supra* to the effect that in Oct. 1928 he did away with heating the plunger and heated the cork instead.

We thus have a case where an applicant for a patent made a disclosure in his application as filed. He voluntarily, without any requirement of the Patent Office, cancels the dis-

closure and the claims covering that disclosure. Before cancellation he files another application for an article with utterly different subject matter which has the *disclosure* in the pending application but he *does not* claim it. He has absolute knowledge before cancelling the disclosure that a third party has made and sold and in fact the applicant's assignee has bought machines from that third party for carrying out the method covered by the disclosure and claims as originally filed. The applicant, more than three years after voluntarily cancelling the disclosure and claims for the matter in controversy, and after actual knowledge of the subject matter of the claims in a patent issued to the man from whom his assignee by his order had bought machines from Johnson the patentee, for the purpose of carrying out the method then files an application claiming that which he had originally disclosed and voluntarily cancelled and which for some four years had been in public use and on sale.

The record therefore shows that the case of *Webster* vs. *Splitdorf* cited by the Circuit Court of Appeals in its decision clearly applies. There could be no clearer case for its application than the case at bar.

Quite apart from the decision of *Webster* v. *Splitdorf,* this Court has many times held that in a case where a patentee has delayed asserting his rights and intervening rights have accrued, the patentee will be barred from later asserting those rights. In the case of *Railway Co.* v. *Sayles,* 97 U. S. 554, 563, this Court said:

> "Courts should regard with jealousy and disfavor any attempts to enlarge the scope of an application once filed, or of a patent once granted, the effect of which would be to enable the patentee to appropriate other inventions made prior to such alteration, or to appropriate that which has, in the mean time, gone into public use."

In the case of *Victor Talking Machine Co.* v. *Brunswick-Balke-Collender Co. et al.,* 8 Fed. 2d 41 (C. C. A. 3rd), the Court said:

> "On April 4, 1911, Browning struck from his application for the patent the invention covered by claim 1, and did not reinsert it until June, 1915. Judge Morris held that this unexplained silence for a period of more than four years constituted an abandonment by him of the invention. We think his conclusions on both issues are sound, and affirm the decree on his opinion."

That decision was affirmed by this Court. *Per Curiam,* 273 U. S. 671;

> *Planing Machine Co.* v. *Keith,* 101 U. S. 479 at 485;
> *Consolidated Fruit Jar Co.* v. *Wright,* 94 U. S. 92;
> *Yale Lock Co.* v. *Berkshire Bank,* 135 U. S. 342 at 378-9;
> *Rubenstein* v. *Slobotkin,* 33 F. R. (2) 603 at 608.

It is well settled that where an applicant delays his application in the Patent Office for a long while and then puts in claims which cover improvements that have appeared in the art and patents issued therefor in the meantime, he cannot amend or broaden his claims to cover such devices. Typical cases are *Irving Air Chute Co.* v. *Switlick Parachute & Equip. Co.,* 82 F. R. 2d 645 (C. C. A. 3rd Circuit); *T. H. Symington & Son, Inc.* v. *Symington Co.,* 9 Fed. Supp. 699 at 704; *Insulite Co.* v. *Reserve Supply Co.,* 60 Fed. 2d 433, 435 (C. C. 8), *Hartford Empire Co.* v. *Coe,* 76 F. R. (2) 426.

Such being the law, it is clear beyond question that petitioner in this case having cancelled the method of preheating the cork in his 1927 application for patent and allowed the patent to issue thereon without that disclosure, cannot come in three and one-half years thereafter, when a patent has been issued to Johnson for the matter cancelled and the subject has been in use by Johnson, the respondent in this case as well as the Petitioner and others and obtain a valid patent for the cancelled subject matter.

Petitioner is licensed to use the method and machine of Johnson Patent 1,852,578.

Under U. S. R. S. 4899 petitoner is licensed to use the machine of the Johnson Patent 1,852,578 and to carry out the method set forth in the method claims of that patent.

Respondent bought all of its machines from Johnson between August, 1928 and the spring of 1933 Some of these machines were purchased after the issuance of the Johnson patent No. 1,852,578 (pp. 1102-7 Rec., Vol. 2: Test. Johnson, pp. 222-3 Rec.). By the purchase of these machines, respondent acquired the right to their use from the patentee. The Johnson patent contained 27 claims to the machine and three claims to the method or function of the mechanism of the machine.

Prior to the filing of the application for public use proceedings, by Johnson, and in August, 1933 (pp. 301, 379), petitioner's vice-president and its counsel visited the plant of the respondent and saw a Johnson machine in operation. On December 12th, 1933, petitioner purchased the Johnson patent and took an assignment thereof (pp. 1162-3 Rec., Vol. 2) and, on the same date executed a license to Johnson which license set forth that it was on that date the owner of the Johnson patent and gave Johnson a release for all past infringements of the Johnson patent (p. 1157 Rec.).

The petitioner took title to the Johnson patent with full knowledge that the respondent was using such machines and no subsequent proceeding in the Patent Office can divest the respondent of the rights its acquired from Johnson to use the machines, **particularly when the petitioner does not contest the inventorship of Johnson of the apparatus claims of the machines.**

Keystone Type Foundry vs. *Fastpress Co.*, 272 Fed. 242;

Dable Grain Shovel Company v. *Flint*, 137 U. S. 41;

DeForest Radio Telephone Company v. *United States*, 273 U. S. 236.

The record shows that there were intervening rights and a public use of the method of patent 1,967,195. The facts constituting such intervening rights and such public use were known to petitioner long prior to the filing of the application by Warth for such patent and before the purchase by petitioner of the Johnson patent and the subsequent allowance of the method claims of that patent in the Warth application. This procedure obviously was solely for the purpose of divesting respondent of those rights acquired by the purchase from Johnson of machines for the practice of the method.

Petitioner, by thus buying the Johnson patent and having the claims allowed in patent (1,967,195) granted more than two years after the issue of the Johnson patent, has not only prolonged the life of the monopoly as to the method, but has prolonged the life of the Johnson patent which it owns.

The Johnson patent, with its apparatus and method claims, nominally would have expired in April, 1949, and if the Warth patent 1,967,195 is valid, the Johnson patent, as to the apparatus claims, while nominally expiring in 1949, will in fact be extended to July, 1951, since this apparatus cannot be used without infringing the method claims of the Warth patent 1,967,195.

The effort to conceal the fact of ownership of the Johnson patent obviously was an effort to withhold a material fact from the public.

Keystone Driller v. *General Excavator Co.*, 290 U. S. 240.

There is no conflict of decisions.

Counsel for petitioner has cited a number of authorities and argued that there is a conflict of decisions between the Circuit Courts of Appeal of different circuits. It is unnessary to discuss those cited decisions in detail. No one of them shows a state of facts as shown by this record, viz. claims and disclosure having been stricken from a pending application, the patent issued and then more than two years after its

issuance the inventor tries to get that cancelled and abandoned matter which has gone into public use, into another patent and get the date of the original.

Counsel for petitioner evidently overlooks the fact that the case of *Wirebounds Patents Co.* vs. *Saranac Automatic Machine Co.*, 37 F. (2) 830 relied on by him at pages 5, 12, 19 of his brief was reversed by this Court in 282 U. S. 704. It would seem that if any conclusion could be drawn from the action of this court, it is that the decision of the lower court in that case 24 Fed. (2) 872 is the law. That court properly applied the doctrine of *Webster Electric Co.* vs. *Splitdorf Electric Co.*, because there was a long delay in filing a divisional application and as in the case at bar there was no evidence of inadvertence, accident or mistake.

It will be noted therefore that on an analogous state of facts to those in the case at bar, this Court refused to pass on the question now attempted to be raised by petitioner. Manifestly, there is no conflict between the decisions of the Second and Sixth Circiuts.

The fact that the patentee thought or was informed his claims covered both forms of the invention is no excuse.

Counsel for petitioner cites on page 28 of his brief, two cases to the effect that reliance on an earlier application or patent is an excuse for delay in asserting claims. The two cases cited there are both interference decisions and show an entirely different state of facts than that shown in this record.

In any event, this court has held that the opinion of a patentee or his counsel, to the effect that an earlier patent covered a certain construction is no excuse for delay.

Wollensak vs. *Sargent*, 151 U. S. 221 and cases cited.

McClain vs. *Ortmayer*, 141 U. S. 419.

Radio Condenser Co. et al. v. *Coe*, 75 F. R. (2) 523.

2

The case of *Chapman* vs. *Wintroath*, 252 U. S. page 126 has no application to the facts disclosed by this record.

In *Chapman* vs. *Wintroath*, the Chapmans disclosed the invention in controversy but did not claim it. Thereafter Winthroath filed an application and obtained a patent on the subject matter of the invention. Afterwards, while Chapman's original application disclosing the subject matter was still pending, they filed a divisional application within two years from the issue of the Wintroath patent and copied Wintroath's claims. It was held they could do it because they had originally disclosed it in a pending application. There are no such facts or even remotely analogous facts in the record of this case. In the case at bar, Warth deliberately cancelled the matter, as has been previously pointed out and his patent issued without disclosing or claiming the cancelled matter, and the cancelled matter was dedicated to the public when his original patent issued in 1931, the file of which shows that matter had been cancelled.

This court in *Chapman* vs. *Wintroath* did not lay down any hard and fixed rule to the effect that if a patent issued to another party while an application was pending the applicant could, in every case, as a matter of right copy the claims of the issued patent for interference purposes. On the contrary it expressly provided that there might be cases where even if an application was filed within the two years it would not be in time depending on the circumstances of each case. This court said on page 139:

> "While not intending to intimate that there may not be abandonment which might bar an application within the two-year period allowed for filing, yet upon this discussion of the statutes and decisions etc."

As previously pointed out, the case at bar is one of deliberate abandonment. There are intervening rights of third parties. The subject matter had been cancelled from the appli-

cation (159,743) the date of which petitioner seeks to obtain and the patent had issued on that application.

Obviously *Chapman* v. *Wintroath* has no application to the case at bar.

The invention claimed in both of the patents in controversy is merely for a function and not patentable.

The claims of both Warth patents, Re-issue 19,117 and 1,967,195 are for a *method*. No complete apparatus or machine for carrying out the method is shown, described or claimed. The claims in both of these patents are for a method of securing a center spot by means of a heat fusible adhesive with a cork disk by means of heat and pressure. The claims are for nothing but the function of a machine. Obviously when using a heat fusible adhesive, heat and pressure must be used.

It is well settled by many decisions of this and other Courts that a patent for a result or function cannot be sustained.

Westinghouse Air Brake Co. v. *Boyden,* 170 U. S. 537 at pages 555-8;

E. Van Norden Co. v. *Cheney,* 75 Fed. 298 (C. C. A. 1) at page 302;

Directoplate v. *Donaldson Lith. Co.,* 51 F. R. (2d) 199;

DeForest Radio Co. v. *General Electric Co.,* 283 U. S. 664, pages 682-4.

CONCLUSION.

There is nothing in the record to warrant the exercise by this Court of its discretionary power of review.

The facts in the record do not support the questions presented by petitioner on page 9 of its brief.

The question of infringement of Re-issue patent No. 19,117 is purely one of fact.

The construction placed by the Circuit Court of Appeals upon the claims of Re-issue Patent No. 19,117 is fully supported by the file history of the application for that patent and the facts in the Record.

Patent No. 1,967,195 is invalid for the reason that the subject of the claims thereof was cancelled and abandoned to the public by Warth when he cancelled the description and claims from his application Serial No. 159,743 (the date of which he now seeks to obtain) and thereafter permitted Patent No. 1,788,260 to issue on January 6th, 1931 and permitted the public to acquire knowledge of such cancellation. In the meantime respondent and others had used the method to a large extent commercially.

The Record shows a clear case of intervening rights and the Circuit Court of Appeals properly applied the doctrine enunciated by this Court in *Webster* v. *Splitdorf* to the facts shown in this Record.

The Petition should be in all respects denied.

Dated, New York, N. Y., June 30th, 1937.

IN THE

Supreme Court of the United States,

OCTOBER TERM, 1936.

CROWN CORK & SEAL COMPANY, INC., Petitioner, vs. FERDINAND GUTMANN & CO., Respondent.	No. 1008

Supplemental Brief for Respondent.

On page two of its reply brief, petitioner has quoted testimony given by the Commissioner of Patents on June 24th, 1937 before the Senate Committee on Patents and it is stated in a footnote (p. 2 Petitioner's Reply Brief) that a printed copy of the testimony has been filed with the clerk of this Court.

It seems clear that the principal reason petitioner filed a reply brief is to get before this Court the testimony of the Commissioner referring to the case at bar. We make no comment on the Commissioner's action in discussing a case by title which is now awaiting the decision of this Court upon an application for a writ, and giving his opinion as to what would happen on the granting or refusal of the writ.

Attention is called to the fact that the petition for the writ was filed in May, 1937, the testimony was given by the Commissioner on June 24th, 1937, while respondent's brief was not filed until July 2, 1937. Obviously the Commissioner's conclusions were made *Ex Parte*.

We emphatically protest against the action of petitioner in filing a copy of that testimony with this Court, and using

it in his brief in an obvious attempt to possibly influence the decision of this case.

Apart from quoting the Commissioner, the reply brief merely presents cumulative arguments on points already covered in petitioner's main brief, but respondent considers it advisable to answer the same in order to call attention to certain inaccurate and inconsistent statements and arguments.

It is thought it may be helpful to this Court in considering this case to very briefly restate the undisputed facts supporting the decision of the Circuit Court of Appeals for the Second Circuit, which bear on the two method patents in controversy, and upon which the petition for the writ herein is based.

Details as to the patents are as follows:

PATENT No. 1,788,260, App'n. Jan. 7, 1927, Ser. 159,743 Issued Jan. 6, 1931.

The application as originally filed described and claimed a method of applying heat by means of a heated plunger and also preheating the cork. Description and claims as to preheating the cork cancelled Dec. 3, 1930. Patent as issued described and claimed a method of "upon assembly applying simultaneously to the spot pressure and sufficient heat etc."

RE-ISSUE PATENT No. 91,117 Application filed Jan. 23, 1934 Issued March 20th, 1934.

A re-issue of Pat. No. 1,788,260. Had same claims as the parent case with two additional claims Nos. 3 and 4 calling for cooling under pressure. Held valid and infringed by the District Court. Court of Appeals reversed District Court on grounds that respondent did not use the method covered by the claims, and that if said claims were construed to cover respondent's method they would be invalid because anticipated.

APPLICATION Ser. No. 494,201 Entitled "Bottle Cap Spot Material," Filed November 7, 1930.

A division of Patent 1,788,260. As filed contained a *disclosure* of the "Preheating Method," but made no *claims* therefor. All claims were for "Bottle Cap Spot Material." These were allowed February 2nd. 1933 (pp. 1981-1985 Rec.). Lapsed for non-payment of fee. Renewed and again allowed to lapse (1996-2000) and finally abandoned.

PATENT No. 1,967,195 Application filed April 4th, 1933. Issued July 17th, 1934.

Patent states on its face "Original application November 7th, 1930, Serial No. 494,201, which in turn is a division of Serial No. 159,743, January 7th, 1927, now patent No. 1,788,260 dated January 6th, 1931. Divided and this application April 4th, 1933 Serial No. 664,410."

Referred to as the "Preheating Method" patent.

On April 5th, 1932 patent No. 1,852,578 containing 27 claims for an apparatus and 3 claims for the preheating method issued to Johnson upon an application filed November 26th, 1929.

The only claims in Patent 1,967,195 are the 3 preheating *method* claims copied by Warth for interference purposes.

The District Court held Patent No. 1,967,195 valid and infringed, but the Circuit Court of Appeals held that the facts above stated invited the operation of the two year rule laid down by this Court in *Webster Co.* v. *Splitdorf Co.*, 264 U. S. 463.

Petitioner contends that because the Circuit Court of Appeals did not expressly state there were intervening rights the doctrine of this Court in *Chapman* v. *Wintroath*, 252 U. S. 126 applies because Warth filed his application for the preheating method within two years of the issuance of the Johnson patent.

It is the position of respondent that the facts of this case are so different from the facts in *Chapman* v. *Wintroath*, *supra*, that the same does not apply.

That apart from the question of intervening rights decision of the Circuit Court of Appeals is in accordance with the established practice of the Patent Office and decisions of this and other Courts.

That in any event the Circuit Court of Appeals did in fact find that rights had intervened which made it impossible for Warth to obtain a valid patent.

POINT 1.

On the facts set forth in the opinion of the Circuit Court of Appeals its decision is clearly correct under the rule laid down by this Court in *Webster* v. *Splitdorf* and in accordance with a long line of decisions of this and other Courts and the well established rules of the patent office.

In an attempt to show that Warth's action in the Patent Office did not amount to abandonment, petitioner relies upon the case of *Writer* v. *Kiwad* in its reply brief (p. 9).

The District Court cited this case in its opinion and said (pp. 2095-6):

> "The subject matter was not abandoned, as suggested by defendant, but was specifically reserved by continuous inclusion in the divisional application, and later in the second division. This has been approved and is the usual practice. Writer v. Kiwad, 63 Fed. (2d) 259."

With the utmost deference to the District Court and to petitioner, it is submitted that the facts in *Writer* v. *Kiwad* are not in any way analogous to the facts in the case at bar and the case has not the slightest application. An inspection of the cited case shows that a parent application of Kiwad was filed in 1926 and claimed the invention in issue. That pursuant to a requirement of division, Kiwad

cancelled the claims and the drawing and descriptive matter in 1927. The Writer application was filed in November, 1928 and matured into a patent in August, 1929. Kiwad did not file his divisional application until December, 1929 after his attention was called to the Writer patent. The interference was declared on March 18th, 1930.

The case was entirely and radically different from the case at bar for the reason that Kiwad's parent application had not matured into a patent before his divisional case was filed. *The claims in the Kiwad parent application were not allowed until April, 1930, four months after the filing of his divisional application* (63 F. R. (2) at p. 264).

The co-pendency of an application containing a disclosure of the preheating method, but not claiming it, and claiming a different invention, viz, an article of manufacture only, does not entitle Warth to the date of filing of the parent case.

The argument of counsel for petitioner is of course that inasmuch as Warth had the disclosure in his co-pending application 494,201, Warth could make the claims any time within two years from the date of issue of the Johnson patent. That was the holding of the District Court and petitioner relies upon the decision of this court in *Chapman* v. *Wintroath* to support his argument.

The District Court erred and counsel for petitioner errs in this respect for the reason that the co-pending application 494,201 was for a *different invention.* In the case of *Jones* v. *Larter,* 1900 C. D. 111, 92 O. G. 383, the Commissioner of Patents said at page 115:

> "The presumption of dedication to the public by disclosure in a patent may, it is true, under certain circumstances be overcome by having a concurrently pending application claiming it; but *I know of no authority* for holding that it is overcome *by an application which does not and was not intended to claim it,* merely because the claims are inserted therein long after the patent on the other case issues."*

* Italics ours unless otherwise stated.

The Commissioner in his decision cited

James v. *Campbell,* 104 U. S. 356, 382;
Miller v. *Brass Co.,* 104 U. S. 350;
Mahn v. *Harwood,* 112 U. S. 354.

That case was followed and quoted from in the case of *Union Typewriter* v. *L. C. Smith & Bros.,* 173 F. R. 288, 297, affirmed by the C. C. A. 3rd Cir. in 181 F. R. 968.

As has been pointed out, application Ser. 494,201 was an application for patent on "Bottle Cap Spot Material". The *claims* were confined to that invention. The claims, after repeated rejection, were finally allowed. Warth could not have put claims for the *method* in that application after the patent 1,788,260 issued, under the authority of *Ex parte Stimson* 1916 C. D. page 20; 226 O. G. 699. In that case the Commissioner of Patents said:

> "It appears from the remarks accompanying the amendment that when the application was prepared the process claims were deliberately omitted. The inventions *are so widely different* that it would be necessary to support the process claims by a supplemental oath.
>
> No reason is seen for permitting an applicant to nullify an election deliberately made and after the application has been prosecuted to an allowance *on one invention present claims for an entirely different invention, even for the purpose of interference.*"

Warth deliberately abandoned the invention (if it is invention) of the method of preheating the cork.

It is well settled that when an applicant is compelled by the Patent Office to accept a narrow claim, he cannot thereafter have a construction of the claim either in the same or in another application covering that which was rejected by the Office in view of the art. See the case of *I. T. S. Rubber Co.* vs. *Essex Rubber Co.,* 272 U. S. 429. If dissatisfied with the action of the Patent Office, he should appeal. He is bound by the claim accepted.

In the case of *Splitdorf Electrical Co.* v. *Webster Electrical Co.*, 283 Fed. Rep. page 83 the Court said at page 93:

> "An inventor of a patent may lose his right thereto by waiver, by public grant, by estoppel, or by laches.
>
> "By failure to apply to the government for a patent within the statutory period of two years, he loses his right as effectively as if he made specific grant thereof to the public. If in his application he seeks but a part of the claims to which he is entitled, he waives all right to those not claimed. He makes a donation to the public, and his right to the monopoly is gone forever."

That case was affirmed by this Court in 264 U. S. 463 and is relied upon by the Court of Appeals in refusing Warth the date of either the parent application of January 7th, 1927 or of the divisional application 494,201 of November 30th, 1930. Warth's prosecution of the patents here involved brings him squarely within the foregoing rule.

In the case of *Stromberg* vs. *Motor Devices Co.* v. *Benecke & Kropf Mfg. Co.*, 10 F. R. (2d) 405 (C. C. A. 2nd) an application for a divisional patent was not made until more than three years after requirement. The Court held on page 406 that in view of Sec. 4894 and 9438 R. S. an application filed more than a year after requirement for division should be treated as abandoned.

Warth by cancelling claims for and the description of the preheating method from Pat. 1,788,260 (Reissue 19,117) dedicated the part not claimed to the public. In the case of *Deering* v. *Winona Harvester Wks.*, 155 U. S. 286, the court said at page 296:

> "It is possible that Olin was entitled to a broader claim than that to which he limited himself, but if he described and claimed only a part of his invention, he is presumed to have abandoned the residue to the public. McClain v. Ortmayer, 141 U. S. 419."

In the case of *Rifle Co.* v. *Whitney*, 118 U. S. 22, this court held that there may be abandonment of an invention after application as well as before. The court held at page 24:

> "The decision of the Commissioner in favor of the applicant, upon the question whether the invention has been abandoned, is not conclusive, but may be contested and reviewed in a suit brought for the infringement of the patent."
>
> "* * * An inventor, whose application for a patent has been rejected, and who, without substantial reason or excuse, omits for many years to take any step to reinstate or renew it, must be held to have acquiesced in its rejection, and to have abandoned any intention of further prosecuting his claim."

The case of *Vapor Car Heating Co. v. Gold Car Heating and Lighting Co.*, 296 F. R. 188 (C. C. A. 2nd), is to the same effect.

Warth is estopped by his action in the Patent Office on the application resulting in Patent 1,788,260 from obtaining a patent at any time on the preheating method.

An inspection of the file history of the application for the parent patent (referred to on pages 13-14 of our main brief) shows that the main and, in fact, the only method considered by applicant was that of using a heated plunger. Contrary to the erroneous statements on page 27 of petitioner's main brief and page 12 of its reply brief, the original application as filed stated (p. 1490 Rec.):

> "In carrying out the invention according to what is now considered the best practice the coating will be softened by heat after the crown is assembled. This may be acomplished in any suitable manner, as by a *heated plunger* or a plunger and *heated table*. The heat softens the coating and renders it adhesive and the pressure serves to unite the metal foil spot to the cork."

The claims as filed and amended did not differentiate between heating the plunger and preheating the cork. They were broad enough to cover both methods. The Patent Office in its two actions (pp. 1497 and 1500 Rec.) did not call for division as to the two methods. Nothing was said either by the Patent Office or by applicant in his amendments about

preheating the cork or alternate methods (see subdivision 10 of Amendment (p. 1524 Rec.) which describes the method and advantages of a heated plunger). The specification in referring to the preheating method simply said (p. 1490 Rec.):

> "It may be desirable * * * This may be accomplished, for example, by preheating the assembled crowns."

The Patent Office held that neither method was patentable. After final rejection and appeal filed, applicant voluntarily cancelled the preheating description and took a narrow claim for all he could get, viz., the method of using a heated plunger. On the Examiner's consent and recommendation to the board to allow that single narrow claim, the appeal was withdrawn (p. 1529 Rec.).

On pages 10 and 11 of its reply brief, petitioner, in answer to the statement in respondent's brief to the effect that the file of the parent patent shows the preheating claims and description had both been cancelled, states:

> "But this contention overlooks the fact that before cancellation of the specific disclosure the same had been embodied in the divisional application filed in November, 1930. This is the only way an applicant can reserve matter cancelled from a pending application."

It is of course quite true that an applicant can file a divisional application before the parent patent issues, and we may assume that anyone looking at the file of an issued patent might be justified in thinking that some of the subject matter had been reserved in a divisional application. That is true, however, only as to the disclosure of the issued patent. If the file shows that certain matter has been cancelled both as to the disclosure and claims, the conclusion is inevitable that the applicant had abandoned the cancelled matter. If an applicant has cancelled both description and claims, as was done in the case at bar, and put in a co-pending application, Rule 43 of the Patent Office requires

that a cross reference be made to the pending application *ex parte Weston,* 390 O. G. 265. Warth did not do this. He could make no such reference because he had no application pending with claims to any method whatsoever. There is no cross reference in the file of Ser. 159,743 resulting in Patent 1,788,260. The file of that patent therefore clearly shows that both the disclosure and claims for preheating the cork were cancelled, abandoned and dedicated to the public.

By failing to appeal from the action of the Examiner in refusing in the parent application to allow the broad claims now sought to be sustained in the preheating patent, Warth is now estopped from contending those claims are valid. *I. T. S. Rubber Co.* v. *Essex Rubber Co.,* 272 U. S. 429. In *re Ellis,* 86 F. R. (2d) 412, the applicant made an application which was rejected. He filed appeal therefrom and subsequently brought a suit under Section 4915 which he failed to prosecute. The Patent Office and Court of Customs & Patent Appeals held he was estopped from making claims of the same scope in a subsequent application because he voluntarily abandoned the suit under 4915.

In the case of *In re Baker,* 74 F. R. (2d) 306 (Ct. of Customs & Pat. App.) it was held that the decision of the Commissioner of Patents rejecting certain claims in an earlier application was *res adjudicata* on the issue of patentability of substantially similar claims in a subsequent application. Failure to appeal constitutes abandonment and estoppel. *Ex parte Crane,* 32 Pat. Q. 80.

In re *Stanton,* 86 F. R. (2d) 337 certain claims were rejected in an application for reissue on the ground of estoppel because the claims were as broad or broader than claims which had been cancelled in order to secure the original patent.

In re *Crowell,* 79 F. R. (2d) 746 is to the same effect and was a case of an application for reissue of a divisional patent. It was held the applicant was estopped because the claims were substantially the same subject matter as applicant cancelled in order to obtain the original patent.

In re *Murray,* 64 F. R. (2d) 788 the Court of Customs & Patent Appeals held that that if the invention involved was disclosed in an original or amended application and claims incorporating such invention were withdrawn or cancelled before the patent issued, the applicant was estopped from further claiming such invention by way of reissue.

In *ex parte Moorhead,* 173, O. G. 1079 the Commissioner of Patents held:

> "Applicant is no more entitled to prosecute, after a requirement for division, claims to subject-matter which had never before been claimed though disclosed in the application and the amendment containing such claims, accompanied by a supplemental oath, than he is to prosecute claims relating to the same subject-matter as the claims which had been cancelled under the requirement for division."

In the case of In re *Woodsome & Swan,* 1926 C. D. 176; 10 F. (2d) 1003 (Ct. of App. Dist. of Col.) the application was for paper drying-rolls. Certain claims were specific claiming the steam using device as paper-drying rolls. The remaining claims were generic, calling for steam using apparatus. The Patent Office required division because of the difference in scope of the claims. The applicants took no appeal, cancelled the broad claims and the patent issued Sept. 5, 1922. Before the patent was issued and in February of 1922, applicants filed an application containing the cancelled claims and called it a divisional application. The patent was refused by the Office on the ground that to allow the second application would constitute double patenting. The action was affirmed by the Court of Appeals of the District of Columbia.

The parent case having issued Warth cannot in an application filed after its issue obtain the date of the parent case for that subsequently filed application.

In the case of *In re Spittler & Krische,* 1908 C. D. 374 a patent had issued and after its issue it was sought to obtain

its date for a divisional application on matter which was disclosed in the original patent as filed. The Court of App. Dist. Col. said at page 376:

> "But having amended that application so as to conform to the ruling of the Examiner, it was merged and the patent issued thereon. After that there was no application pending in the Office as a foundation for a division. The proceeding having been closed by the issue of the patent, there was nothing to be continued. The rule which permits a divisional application to relate back to the filing date of the original which also discloses its subject matter, as long as it remains open in the Patent Office, is a very liberal one that sometimes works hardship upon intermediate inventors, and it ought not to be extended to cases not clearly within it."

In the case of *Wainwright* v. *Parker,* 1909 C. D. 379, 142 O. G. 1116, an application as originally presented disclosed four different species. Claims sufficient in scope to cover all were originally included, but after repeated rejections the application was limited without appeal to one of the species and the drawing, specification and claims were so amended as to eliminate all reference to the device involved in the interference. The application was allowed and went to patent. Four years afterwards the appellant filed the application in interference and sought to get the date of the original application. This was denied and the Court of Appeals said:

> "His original application having eventuated into a patent, there was nothing left pending before the Patent Office upon which it could act, or to which the later application could attach."

In the case of *Conover* v. *Downs,* 35 F. R. (2nd) 59, (Ct. of Cus. & Pat. Appeals) Conover filed an application showing both an apparatus and a process. No claims were made to the process. The patent issued on Dec. 9th, 1919 claims for the process were made in an independent application Nov. 28th, 1921. The Court said at page 60:

"In view of the fact that the claims for the process were for a different invention, than that involved in the patent of Dec. 9, 1919, appellant was required by the Primary Examiner to cancel these claims. This ruling was accepted by appellant and the claims were cancelled. Accordingly appellant had no proper application for the invention pending in the Patent Office until he filed his independent application on Nov. 28th, 1921, nearly two years after his application of April 30, 1919 had matured into a patent. There was, therefore, no parent application pending in the Patent Office to which his application of Nov. 28th, 1921 could relate or attach."

In the case of *Model Bottling Machinery Co.* v. *Anheuser Busch Brewing Assn.*, 190 F. 573 C. C. A. 8th Circuit, a patent disclosed both a process and an apparatus. The patent for the apparatus issued and after its issue, an application was made and a patent obtained for the process. The Court at page 576, after quoting from the case of *Hayes-Young Tie Plate Co.* v. *St. Louis Transit Co.*, 137, F. 80, said:

"If, as stated in the foregoing case, the abandonment of an application destroys the continuity, and a subsequent application must be treated as a new and independent proceeding, how can it be said that there is any continuity between an application which did not make claim to the process, but only to the machine, and a subsequent application for the process."

"Among the numerous cases cited by appellant in support of the claim of continuity, we find none where it has been held that, when a patent has been issued to a party for all he claimed in his application, the party may *subsequently make a new application for a new patent upon omitted matters*, and that such new application was a continuation of the first or original application, etc."

It would seem clear, therefore, that in this case Warth having cancelled his disclosure and claims for the preheating method in order to obtain a patent, should not be al-

lowed to file a subsequent application with the preheating claims more than two years after the parent application issued without the disclosure or claims, and then be allowed the date of the application from which he cancelled them.

Petitioner cites several cases holding that a divisional application is nothing more than an amendment to the original application. Petitioner has not cited and cannot cite any case where an amendment has been made to a patent after its issue. The cases cited by petitioner do not support his argument that the application for the patent for preheating claims No. 1,967,195 is an amendment to No. 494,201 which was pending with the parent application and had the disclosure *but no claims for the method.* The application for Ser. 494,201, as has been pointed out, was for a *different invention.* It was for Bottle Cap Spot Material. It had been allowed with claims for the strip material, when the application for the preheating method was filed (p. 1985 Rec.). The rules of the Patent Office do not permit an applicant to prosecute one form of an invention and obtain allowance therefor and subsequently present claims for the first time for a different invention.

These and other authorities clearly hold that the decision of the Circuit Court of Appeals is not, as contended for by petitioner and the Commissioner of Patents, in conflict with the well established practice of the Patent Office. On the contrary, it is in strict accordance with the practice of the Patent Office.

Those decisions as well as the decisions of this court to which we have referred, hold:

1. That an inventor must be diligent in asserting claims for his invention;

2. That where an inventor acquiesces in rejection of broad claims, and does not appeal from the ruling of rejection, he is estopped from asserting the same claims or similar claims in an application filed after the patent granted on the application in which the claims first appeared;

3. That a divisional application must be filed before the parent case issues;

4. That the mere *disclosure* of the subject matter in an application copending with the parent application is insufficient to entitle the inventor to the date of the parent case, if the copending application is for a different invention than the parent and the invention is not *claimed* in the copending application.

POINT 2.

The record shows there are intervening rights. The Court of Appeals in its decision found there were intervening rights. This Court has the power to inspect the record to ascertain whether the decision of the District Court is supported by the record.

The Circuit Court of Appeals in discussing the two method patents (pp. 2150-54 Rec.) and their history in the Patent Office, said (p. 2154 Rec.);

> "He (Warth) made no claim for preheating until more than two years thereafter, namely, April 4, 1933. *In the meantime a patent containing claims for the preheating method had been granted to Johnson on April 5th, 1932,* etc."

Because the Court of Appeals did not use the expression "intervening rights" and state in so many words that it reversed the finding of the District Court on that point, petitioner argues that it acquiesced in the conclusions of the lower court in that regard. This argument is fallacious. The language in the opinion of the Court of Appeals last quoted indicates that it did in fact consider the issuance of the Johnson patent to have given Johnson paramount rights since Warth's disclosure of the preheating method was lying

dormant and unclaimed in the Patent Office in an application for a different invention in which no claims for any method of any kind were ever made.

The Record shows and the Court of Appeals might well have held that the Cohn Patent No. 1,921,808 (p. 768 Rec.) applied for on July 20th, 1932, issued August 8th, 1933 is an intervening right. It shows the preheating method and is hereafter referred to.

In its holding, the Circuit Court of Appeals followed a long line of decisions mentioned in its opinion on page 2154 of the record. Those cases, and decisions of this and other courts, hold **that an applicant is not entitled, by amendment, to so enlarge the scope of an original application as to enable him to appropriate the inventions of others.**

The case of *Powers-Kennedy Co.* v. *Concrete Co.*, 282 U. S. 175, in its main essentials and its facts is very similar to the case at bar. It appears on page 184 of that case that McMichael recognized the priority of Leake, and, as a result, purchased and took an assignment of Leake's patent while his own application was pending, to dispose of an interference declared by the Patent Office. Leake did not offer evidence or press his claim to priority and the McMichael patent was granted in 1915, and the Leake patent in 1917, both of them, as in the case at bar, being owned by the same company. The Court said, pages 185 and 186:

> "And, even if the mode of operation is as claimed, it is to be remembered that Leake in his application of October 7th, 1907, uses the same words to describe the operation of his nozzles as we find McMichael subsequently inserted in his specifications and claims. When this application came into interference with McMichael's, he, of course, became familiar with Leake's claims. It is significant that he then amended his claims, almost in the very words of Leake. This of itself destroys the patent. Railway Co. v. Sayles, 97 U. S. 554; General Electric Co. v. Sangamo Electric Co., 174 F. 246; Lopulco Systems Inc. v. Bonnot Co., 24 F. (2d) 510."

The rule announced by the Supreme Court applies with greater force against the petitioner here than it did in the cited case, for the reason that in the case at bar Warth, while originally disclosing and claiming the preheating step, cancelled them from his original application and allowed the patent to issue without either claims or disclosure for that method. Petitioner in the case at bar when it purchased the Johnson patent, as in the cited case, pressed its claim to priority on the Warth application filed subsequently to the issue of the Johnson patent.

The principle of the *Powers-Kennedy* case has been followed by this court in *Eagleton Mfg. Co.* v. *West-Bradley Co.*, 111 U. S. 490.

Corbin Cabinet Lock Co. v. *Eagle Lock Co.*, 150 U. S. 38 at page 43 (a case of reissue);

Also in the following cases:

Jones v. *Freed-Eismann Radio Corp.*, 47 F. (2d) 174 (C. C. A. 2nd);
Insulite Co. v. *Reserve Supply Co.*, 60 F. (2d) 433 at 435 (C. C. A. 8th);
Bloodhart v. *Levernier* 64 F. (2d) 367 at 369 (Ct. Cust. & Pat. App.).

The petitioner, on page 5 of its reply brief, cites the case of *Adamson* v. *Gilliland*, 242 U. S. 350 in support of its contention that this Court cannot look into the Record. A reading of that case shows that this Court went carefully into the Record and discussed in detail the testimony of one of the witnesses. We submit therefore that the case is clearly an authority for the proposition that this Court may look into the Record to see whether the finding of the District Court is supported by the evidence.

Respondent is not asking this Court to pass upon conflicting testimony. Respondent's contention is that the documentary evidence and undisputed oral testimony of witnesses for both sides shows that the District Court erred in

concluding there were no intervening rights, and that there is no evidence to support its finding.

The findings of the two lower courts in this case are not unanimous. There was a dissenting opinion. The Circuit Court of Appeals in reversing the finding of the District Court as to infringement of Re-issue Patent 19,117 necessarily and expressly found (contrary to the finding of the District Court) (pp. 2151-2 Rec.) that defendant uses a different method, viz., a cold cutting punch and preheats the cork.

All the evidence, documentary and oral, shows that respondent had during the entire period of its manufacture of center spot crowns used the method of preheating the cork. The stipulation offered by petitioner at the opening of the trial (p. 733 Rec.) (as its only proof of infringement) shows that the method respondent used in making the alleged infringing caps, was set forth in Johnson Patent No. 1,852,578 and the Cohn patent No. 1,921,808 (p. 768 Rec.). The Cohn patent shows that it was applied for on July 20th, 1932 (while Warth's disclosure for the preheating method was lying unclaimed in the Patent Office). The Cohn patent shows the method of preheating the cork the same as in the Johnson patent. The only difference between the Johnson and Cohn patents is that the latter places the center spots on the cork discs and the cork discs in the metal shell all in one machine, whereas the Johnson patent puts the center spot on a cap, the cork disc of which has been previously secured to the metal shell in another machine (pp. 292, 392-3 Rec.)

Petitioner's own documentary evidence (Exs. 36 and 37 pp. 781-83 Rec.) in connection with petitioner's cross examination of Johnson in connection with those exhibits shows conclusively that Johnson found the heated cutting plunger unsatisfactory and eliminated it and preheated the cork in his machines in Oct., 1928 (p. 238 Rec.).

The public use proceeding instituted by Johnson during the interference between his patent and the Warth applica-

tion (Respt.'s Ex. U, p. 1121-etc. Rec.) consists of affidavits, one of them by Johnson's attorney, who prepared the application, and by his draftsman, to the effect that machines like those shown in the Johnson patent, a copy of the drawing of which was attached to the affidavit, were made as early as January, 1929 There is no evidence put in by petitioner to contradict the facts set forth in those affidavits. They were received in evidence without objection by petitioner's counsel.

There is evidence that petitioner bought five machines from Johnson between March and July 1929. An extract of the letter from petitioner ordering these machines is quoted on page 23 of our main brief. Those machines necessarily had the method of preheating the cork. As pointed out, Johnson abandoned the heated plunger in October, 1928 and preheated the cork.

Both the District Court (p. 2081 Rec.) and the Circuit Court of Appeals (p. 2153 Rec.) found that both parties in commercial practice used the method of preheating the cork. The finding of the District Court to that effect is hopelessly inconsistent with its holding that there was no sufficient evidence to show that respondent had, as testified to by its witnesses Cohn and Rasmussen (pp. 292-3, 287 Rec.) always used a cold cutting punch and preheated the cork, either by a gas flame or electrically heated plungers. The cross-examination of respondent's witnesses by counsel for petitioner (pp. 349-50 Rec.) establishes that fact. There is no evidence to the contrary.

The references made to the record by petitioner on pages 6 and 8 of his reply brief do not support the conclusions attempted to be drawn therefrom. On page 6, petitioner refers to the testimony of Cohn and argues from the references to the record that the machines bought by Johnson in September and December, 1928 and 1929 did not have the preheating device "since they are conceded to have been like the earlier 1928 machines which did not." There is no such concession either in the record nor in respondent's brief. Peti-

tioner says on page 6 that Cohn so testified about Exhibit Q and cites the record (p. 289 Q. 93). All that Cohn said was that, in addition to the mechanism for inserting the center spot, the machines had mechanism for inserting the cork disks. There is not a word about the preheating method on that page. Cohn was also shown (Q. 87 Ex. P) a bill from Johnson dated August 28th, 1931 for a machine with a standard drum.

The uncontradicted testimony of respondent's witnesses Cohn, Rasmussen and Eisen (pp. 314-16, 390, 375 Rec.) shows that a machine was bought from Johnson on July 17th, 1928 (Ex. S, p. 1108 Rec.) which did not have a drum to hold the caps after the center spot was inserted under pressure while cooling. For that reason the center spots fell off and were returned by the Goetz Company and the caps were put through the machine a second time. Another machine was bought by petitioner in August, 1928 with a standard drum (Ex. P, p. 1101 Rec.). After a cooling drum was used, no further trouble was had and the center spots stayed on (pp. 390, 375). The evidence clearly shows that respondent had always preheated the cork when applying center spots as far back as 1924-5. Petitioner's cross-examination of Cohn and the other witnesses for respondent emphasized that fact (pp. 349-50, 383 Rec.). It is submitted that it is most improper for petitioner to make statements of fact that are not supported by the record. We further protest against the statement on page 6 (Petr.'s Reply Br.) to the effect that our main brief *admits* the first two machines did not have a preheating device. An inspection of that brief (p. 20) shows that we made no such admission. We simply said that we *assumed*, for the purpose of appeal, that they did not.

IN CONCLUSION.

In opposing the application for the writ herein, counsel for respondent have to some extent discussed the merits of the whole case, but do not thereby concede that in any view of it the case can be considered a proper one for certiorari.

It is submitted that the law as to the effect of abandonment of an invention, delays in filing an application, the effect of rights that intervene during such delays, the effects resulting from the disclosure of an invention, and the failure to claim same, and the effect of public use of an article made pursuant to a certain method have been before this Court and other Courts and settled by the decisions referred to in this and our main brief. Hence, this cause does not present any questions of law which are not well settled.

The practice in the Patent Office as to the granting of patents upon divisional applications is also well settled, and the fact that the Patent Office did not follow the well settled law and practice in granting the patents here involved is not proper ground for the grant of certiorari.

It follows that the case presents no "question of federal law which has not been, but should be settled by this Court"; there is no question of public interest involved, nor is there any conflict between decisions of circuit courts of appeals within the meaning of rule thirty-eight.

The application for the writ should be denied.

Dated, New York, N. Y., September ninth, 1937.

IN THE

Supreme Court of the United States.

OCTOBER TERM, 1937.

CROWN CORK & SEAL COMPANY, INC., Plaintiff-Petitioner, vs. FERDINAND GUTMANN & CO., Defendant-Respondent.	No. 72

BRIEF FOR DEFENDANT-RESPONDENT.

Petitioner filed an application for a writ of certiorari to review a decision of the Court of Appeals, Second Circuit, in regard to certain patents, alleging conflict of decision between different Circuit Courts of Appeal, which application was granted by this Court on October 11th, 1937. The decision of the Circuit Court of Appeals shows that originally the suit was brought on six patents, four of which for articles were held invalid by the Courts below. The only patents, therefore, involved in this appeal are the two method patents to Warth, viz., reissue patent No. 19,117, held not infringed by the Circuit Court of Appeals, the parent application of that patent, No. 1,788,260, and its two alleged divisions, one of which is Patent No. 1,967,195 held invalid by that Court.

While petitioner's brief states the main facts in the case, it does not fully set forth all the facts which we believe support the findings of laches and abandonment made by the Circuit Court of Appeals.

It is thought that a detailed statement of the proceedings in the Patent Office relating to the patents involved is necessary and will be helpful, and such a statement is accordingly set out under each patent and each alleged divisional application.

The Patent Office proceedings on the application Ser. No. 159,743 for Patent 1,788,260 (the original of reissue 19,117).

The application which resulted in Patent 1,788,260, (original of the re-issue), was filed on January 7th, 1927. It stated that the invention was for a method of producing closures of the type in which a sealing disc has a metal foil facing (pp. 1244-5, Rec.). The specification as filed stated, (p. 1246, Rec.):

> "In carrying out the invention according to what is now considered the best practice, the coating will be softened by heat after the crown is assembled. This may be accomplished in any suitable manner, as by a heated plunger or by a plunger and heated table."

It also contained the following statement:

> "It may be desirable to secure the metal foil spot in position, prior to the heat and pressure steps, sufficiently to prevent dislodgment of the spot during any interval between assembling and final sticking. This may be accomplished, for example, by preheating the assembled crown, to soften the coating as soon as the metal foil spot is deposited."

As filed, it contained six method claims and three article claims for an *adhesive*. The method claims are found at pages 1247/8 of the record.

The first Office action, (p. 1250, Rec.) required division between the method claims and the claims for the adhesive. On March 14th, 1928, (p. 1251, Rec.) the claims to the adhesive were cancelled, with the statement "the subject matter thereof being reserved for divisional application."

On January 11th, 1929 (p. 1253, Rec.) the method claims were rejected by the Patent Office, the Examiner stating:

> "Claims 1 to 6 are rejected on any of the references cited which disclose the coating of a metallic foil with an adhesive which is rendered soft by heat, applying the

coated metal to cork and holding under pressure until the adhesive hardens."

The Office letter also stated that a drawing was required, but need not be furnished until some allowable matter was found in the application.

An amendment was filed on June 26th, 1929 cancelling claims 1, 4 and 6; amending claim 5 by inserting "cutting a facing spot from the coated foil"; and inserting—metal foil spot—in lieu of "coated metal foil."

The remarks accompanying the amendment emphasized the advantage of the thermoplastically coated strip.

On February 4th, 1930 the application was finally rejected (p. 1256, Rec.). On July 18th, 1930, a notice of appeal to the Board of Appeals was filed by applicant (p. 1257, Rec.).

Applicant's attorneys, after an interview with the Examiner and on November 25th, 1930, filed a request with the Board of Appeals for the dismissal of the appeal on the ground that the Examiner had allowed one claim. The original method claims were all cancelled by an amendment filed December 3/30 (pp. 1265-1274) and one narrow claim, found at page 1275 of the record was inserted which is now claim 1 of the patent and also claim 1 of re-issue 19,117 involved in this suit. The decision of the Board approving dismissal of the appeal on the ground that the Examiner had found a single claim allowable is found at page 1264 of the record (See also p. 1285). That claim was filed December 3rd, 1930.

That amendment greatly enlarged the specification and it deliberately cancelled, without any requirement by the Examiner, the matter we have quoted on page 2 of the brief, *supra*, viz:

> "It may be desirable to secure the metal foil * * * by preheating the assembled crown, etc."

A drawing (that shown in the issued patent) was filed with the amendment showing the heated plunger and heated table only.

Subsequently on December 11th an amendment was made inserting an additional claim 2 which is the same as claim 1 with the exception that it was limited to the use of metal foil spot material. The amendment accompanying it contained the following (p. 1287 Rec.):

> "The foregoing claim contains all of the limitations of the claim allowed, but is somewhat more specific etc."

The case was allowed on December 11th, 1930 and the patent issued on January 6th, 1931 without any reference to the preheating of the cork which had been cancelled on December 3rd, and with two claims only, viz., 1 and 2.

File Wrapper History of Re-Issue Patent. 19,117.

The application for re-issue of original patent 1,788,260 (just discussed) was filed on January 23rd, 1934.

The reasons given in the petition for re-issue were that there was an error in the specification to the effect that the drying time of the strip was thirty minutes when it should have been three minutes and further that the step of cooling under pressure had been omitted (p. 1159 Rec.)

There was no allegation that original claims 1 and 2 were in any way inaccurrate. There was no allegation that they did not protect the invention.

Two more claims 3 and 4 were added, each of which were the same as original claims 1 and 2 with the adddition of the cooling step under pressure. The re-issue was granted March 20th, 1934 (p. 547 Rec.)

The claims in suit in Re-issue 19,117 are claim 1, which is the same as claim 1 of Patent No. 1,788,260 and claim 3, which is the same with the additional feature of cooling under pressure.

Italics ours throughout unless otherwise stated.

Proceedings in the Patent Office in Warth Application 494,201 filed November 7th, 1930.

This application is referred to on the face of the preheating patent 1,967,195 and purports to be a division of Serial 159,743, filed January 7th, 1927, which resulted in Patent No. 1,788,260 dated January 6th, 1931 (the original of the reissue). Serial 494,201 disclosed the preheating step (p. 1674, Rec.) quoted on page 2 of the brief *supra,* (which was voluntarily cancelled from 159,743 on December 3rd, 1930), *but did not claim it.*

The invention in Serial No. 494,201 is an entirely different invention from either patent 1,788,260 or 1,967,195. Both of those patents are for a method and the claims in both patents are method claims.

Serial 494,201, however, is for an article of manufacture, viz., "Bottle Cap Spot Material" (p. 1675, Rec.). As filed, it had a single claim reading in part as follows:

> "As a new article of manufacture, laminated material in sheet or strip form for the spotting of cushion discs of caps and comprising a layer of water-proof adhesive which is hard at room temperature, etc."

The first Office action dated April 27th, 1931 (p. 1677, Rec.) rejected the claim as obviously fully met by certain patents and stated:

> "This case appears devoid of invention and should be prepared for a final action."

The case was amended on June 16th, 1931 by enlarging the specification and inserting a drawing showing the method of coating the strip. Figs. 3 and 4 of the drawing show a heated plunger and the specification stated (p. 1686, Rec.) that "the punch 20 may be maintained at elevated temperatures, as by means of a burner 23, etc." That is the same drawing and description of the heated plunger as appears in Patent 1,788,260 and in the re-issue, and omitted any showing relating to preheating.

The Patent Office, on December 17th, 1931 (p. 1694, Rec.) again rejected the application on further references and said "This case should be prepared for final action."

The specification was further amended and arguments made for patentability and action was suspended in view of an interference on another application. On January 31st, 1933 another amendment to the specification was put in with two claims for strip material. Those claims were finally allowed on February 2nd, 1933 (p. 1707, Rec.). On the same date the first of the two allowed claims was cancelled for the reason that it was transferred to applicant's co-pending case Serial No. 414,614 (p. 1708, Rec.). Serial 414,614 resulted in Patent 1,899,782 for strip material. That patent was held invalid by the District Court (p. 1781, Rec.) and no appeal taken therefrom (Erroneously called 1,899,762, p. 1830, Rec.). *Serial 494,201 never at any time claimed any method of any kind.*

Application 494,201 was allowed to lapse for non-payment of the final fee and subsequently renewed (p. 1715, Rec.) Other claims were put in, all for strip material. The case was again allowed to lapse for non-payment of the final fee. It was ultimately abandoned and no patent ever issued on it (p. 1728, Rec.).

Proceedings in the Patent Office Re Patent No. 1,967,195 (the "preheating method" patent) and the interference in which it was involved.

The application for this patent was filed on April 4th, 1933. It was accompanied with a letter (p. 1442, Rec.) from applicant's attorney requesting an interference with the Johnson Patent No. 1,852,578 granted April 5th, 1932, and said, with reference to the accompanying application,

> "Attention is called to the fact that claims 1, 2 and 3 are respectively claims 28, 29 and 30 of the patent to Johnson No. 1,852,578 granted April 5th, 1932."

The letter also stated (referring to issued patent 1,788,260):

> "It is to be noted that the issued patent does not disclose the preheating of the crown or pad within the crown. Furthermore, it is to be noted that the said patent was cited by the Examiner against a broader claim (35) presented by Johnson and the said claim was cancelled. However, claims 28, 29 and 30 were allowed over the disclosure of the Warth patent No. 1,788,260."

The three *method* claims of the Johnson patent only were copied by Warth. No attempt was made to copy the twenty-seven apparatus claims of the Johnson patent.

The application as filed also contained a fourth claim which had an apparatus limitation. That claim was cancelled by the requirement of the Examiner (p. 1445, Rec.) because it read upon the patent to Alberti 1,401,300 (p. 1205, Rec.) and the interference was declared.

It appears from the decision of the Examiner of Interferences, (Pet.'s Ex. 85, p. 660, Rec.) that after the declaration of the interference Warth made a motion to shift the burden of proof in order to obtain the filing date of January 7th, 1927 of application 159,743 (Pat. 1,788,260) (p. 332, Rec.). It was denied upon the ground that the disclosure of 159,743 would not support the counts in issue (p. 332, Rec.). The first decision of the Examiner of Interferences is not in evidence, but is dated October 2nd, 1933 (p. 333, Rec.). After that adverse decision, petitioner purchased the Johnson patent and took an assignment from Johnson dated December 12th, 1933 (pp. 333 and 925-6, Rec.).

Subsequently to the purchase from Johnson by petitioner of the Johnson patent on December 12th, 1933 and on March 16th, 1934 attorneys for Warth and Johnson made a stipulation to the effect that the record at final hearing and on appeal should consist of three affidavits. That stipulated record is found at page 1615, Record. At final hearing on the stipulated record (pp. 660 and 664, Rec.) the Examiner of Interferences reversed his prior holding and awarded priority to Warth.

The assignment from Johnson to Petitioner was never recorded (p. 465, Rec.).

Further facts relating to this interference (*Warth* v. *Johnson* No. 66201) are set forth on page 36 *et seq.* of this brief *infra.*

After the interference was decided in favor of Warth and on May 15th, 1934, the Patent Office, in a letter to Warth's attorneys (p. 1450, Rec.) said:

> "The step of heating the pads and the caps called for in claims 1, 2 and 3 should be suitably illustrated in the drawings."

On June 19th, 1934 (p. 1451, Rec.) a drawing was filed containing Figs. 7 and 8 which show means of applying heat to the sealing pads for preheating.

The amendment of June 22nd, 1934 (pp. 1462-3, Rec.) under the provisions of Rule 78, amended the specification by inserting further matter as to preheating the cushion disc or pad in the metal shell.

ARGUMENT.

POINT I.

Laches and Abandonment.

Petitioner's position in regard to the decisions of this Court in the cases of *Webster* vs. *Splitdorf* and *Chapman* vs. *Wintroath* as they relate to the above points are set forth in the Specification of Errors appearing on page 13 of the brief for Petitioner and the "Argument" that follows.

It is respondent's position that any conflict in the interpretation of the rule in regard to divisional applications laid down by this Court in *Webster* vs. *Splitdorf, supra,* is more apparent than real, and is due to the fact that said rule is sufficiently flexible to make it applicable to widely differing factual situations.

In any event, we consider the question of conflict moot in the case at bar for the reason that, as we read the opinion of the Court of Appeals, *Webster* vs. *Splitdorf, supra,* was not cited in support of any arbitrarily fixed time limitation which might be considered to apply to the filing of the alleged divisional applications herein. The resemblance between the *Splitdorf* case and the instant case lies in the fact that in each the inventor deliberately failed to assert a claim while having ample time and opportunity to do so, and only filed his divisional application after another party had obtained a patent for the invention. In each case the action of the inventor was due to "an exigent afterthought, rather than a logical development of the original application". *Webster* vs. *Splitdorf, supra,* at page 264 U. S. pages 463 at 466.

In other words the Court of Appeals based its decision squarely on the ground that the *facts* conclusively established that Warth had intentionally abandoned his invention. This is apparent not only from a careful reading of the opinion below, but the same Court in the case of *Western Electric* vs. *General Talking Pictures Corp.,* 91 Fed. (2d) 922, (Adv. sheets), referring to this case, so stated (p. 927),

> "In the Crown Cork & Seal Co. case, supra, an adverse patent for the same invention had issued to a third party before the divisional application for the patent in suit was applied for. There also the patentee had not only deliberately cancelled the disclosure of the invention from the specification of his original application, but had also cancelled the claims which were sufficiently broad to cover the invention. The patentee had really abandoned the invention, and we said, 'might never have considered the subject worth claiming as an invention' had a patent for the invention not issued to another * * *."
>
> "We also pointed out a distinction to be made between this case and the Crown Cork & Seal Co. case by saying 'But, in the case at bar, for a period of more than two years Warth apparently did not wish to claim the preheating method, having deliberately cancelled the preheating specification from his original application and shaped his claims so as to exclude it and his patent having been granted' January 6, 1935."

(1935 is a printer's error as the Record in this case, and in the original decision of the Court of Appeals, shows the correct date to be January 6th, 1931.)

We submit that Warth's conduct of the proceedings in the Patent Office on the application for Patent. No. 1,788,260 (the original of the re-issue 19,117) set forth fully (pp. 2/4 supra), on the re-issue itself, and the so-called divisional application 494,201 (pp. 5/6 supra) shows a deliberate abandonment on the part of Warth of any intention to assert his right to claims for the preheating step, and made it impossible for him to obtain such claims in any subsequent patent.

Warth's failure, voluntarily, to argue the appeal which he had taken from the Examiners final rejection on the art, pages 2/4 *supra,* in the application for patent 1,788,260 and assert his right, by prosecution of the appeal to attempt to obtain claims for preheating and in place thereof cancelling the claims and disclosure, and permitting the patent to issue without them, not only estops him from making those claims as a matter of law, but indicates an INTENT to abandon them. We temporarily defer discussion of the alleged divisional applications.

There are other indications of this intent. While conducting the application for patent 1,788,260, Warth was more interested in the *Strip Material* than in the *method of applying the heat.* Warth filed an amendment June 28, 1929, page 1255. Record, stating:

> "The Examiner states that any of the references discloses the use of an adhesive rendered soft by heat and applying under pressure. But applicant is not claiming anything so broad as that. *None of the references discloses coating foil with a substance of the characteristics mentioned, drying the coating to render it non-tacky, cutting a spot from the coated foil and assembling by heat and pressure.*"[1]

---

[1] Later, in the allowed claim, Warth further restricted his right to a particular manner of applying heat and pressure, to wit, "applying *simultaneously* to the spot pressure and sufficient heat etc." thus deliberately disclaiming all other ways of applying the spot to the cork.

The arguments and the lengthy amendment made on Dec. 3, 1930, when the description and broad claims covering preheating were cancelled all stressed the undesirable method previously used of cutting the center spots from two separate sheets of gutta percha and foil material and the great advantage of using the thermoplastically coated strip. It was on the theory that the invention consisted in the method of using a thermoplastically coated strip of cap material instead of separate strips of gutta percha and foil or paper that the Patent Office was induced to allow the application. This appears also from the "remarks" in said amendment filed December 3rd, 1930 (pp. 1265-1283, Rec.), especially the matter on page 1278 in regard to the "primary" and "secondary" concepts of the invention, stating them to be the strip, and the enumeration of advantages on page 1280, Record to the same effect.[1]

Having previously cancelled his adhesive claims in response to a requirement for division (p. 1250, Rec.) Warth was, obviously, glad to take what little he could get in regard to a limited claim for a heating method and avoid the risk of receiving nothing as a result of an appeal.

---

[1] "The applicant's invention, from the standpoint of conception, consists in three steps. First, he perceived that the former practices of using (a) paste or glue, or (b) a separate strip of adhesive tissue, were cumbersome and objectionable. He saw the objections and set out to overcome them. The second step in his invention was to supply the medium and method by which these objections might be eliminated. In connection with the second step, he supplied a material of laminated character having (a) one exposed surface which is acid-resistant and gas impervious, and (b) another exposed surface with a thin coating of waterproof adhesive which softens under the application of heat, but is normally hard, so that the material can be conveniently handled. Thirdly, he went a step further and provided a complete method which involves the use of this material in such a way that caps might be more economically produced and without the defects of caps produced according to the earlier methods." (p. 1279, Rec.)

The same amendment (on p. 1280, Rec.) enumerated ten advantages of the invention, nine of which were directed to the advantages of the coated strip and only the tenth referred to heat and pressure.

The decision of this Court in *McClain* v. *Ortmayer,* 141 U. S. 419, is peculiarly applicable to the facts in this case. There the Court said at page 423:

> "Nothing is better settled in the law of patents than that the patentee may claim the whole or only part of his invention, and that, if he only describe and claim a part, he is presumed to have abandoned the residue to the public. The object of the patent law in requiring the patentee to 'particularly point out and distinctly claim the part, improvement or combination which he claims as his invention or discovery,' is not only to secure to him all to which he is entitled, but to apprise the public of what is still open to them."

Warth by having deliberately cancelled and failed to claim that part of his so-called invention relating to preliminarily heating the cork prior to the heat and pressure step as a means of obtaining the necessary heat, clearly, under the above authorities, dedicated that method to the public. To the same effect as *McClain* vs. *Ortmayer* are the following decisions of this Court.

This Court said in the case of *Deering* vs. *Winona Harvester Works,* 155 U. S. 286 at page 296,

> "It is possible that Olin was entitled to a broader claim than that to which he limited himself; but if he described and claimed only a part of his invention, he is presumed to have abandoned the residue to the public. McClain vs. Ortmayer, 141 U. S. 419."

In the case of *In re Ellis,* 86 F. R. (2d) 412, applicant made an application which was rejected. He appealed therefrom unsuccessfully and, subsequently, brought a suit under Section 4915 which he failed to prosecute. The Patent Office, and Court of Customs and Patent Appeals, both held he was estopped from making claims of the same scope in a subsequent application because he voluntarily abandoned the suit under 4915.

In the case of *In re Becker,* 74 F. R. (2d) 306, the Court of Customs and Patent Appeals held that the decision of

the Commissioner of Patents rejecting certain claims in an earlier application was *res adjudicata* on the issue of patentability of substantially similar claims in a subsequent application. The following cases are to the same effect,

Ex parte Crane, 32 Pat. Q. 80;
In re Stanton, 86 F. R. (2d) 337;
In re Crowell, 79 F. R. (2d) 746;
In re Murray, 64 F. R. (2d) 788;
In re Woodsome & Swan, 1926 C. D. 176; 10 F. (2d) 1003 (Court of Appeals District of Columbia).

Obviously this rule would apply with great force in a case where an appeal taken from a final rejection on the Art without any question of requirement for division was voluntarily withdrawn and the rejection acquiesced in by the applicant.

As further showing Warth's intention to abandon the preheating method, attention is called to the fact that two other applications entitled "Bottle Cap and Method of Making Same" were filed by him, one bearing Serial No. 360,895 on May 6th, 1929 (p. 1296, Rec.) and another bearing Serial No. 492,546 (p. 735, Rec.) on November 7th, 1930, in each of which applications the method of applying the necessary heat by means of the cutting plunger is shown. The drawings as to the heating apparatus being the same as in Patent 1,788,260 and the Reissue. In both of those applications method claims were made and cancelled because the Patent Office said the Cap was a separate invention from the method (pp. 757 and 1316, Rec.). No subsequent applications were ever made for these cancelled method claims so far as the record shows.

We submit that, if Warth had considered the preheating step valuable, he could easily and would have inserted a description and claims for the same in either of the two said applications.

The preheating Patent 1,967,195 is not a proper division of either application Ser. No. 159,473 filed Jan. 7, 1927 on which the parent Patent 1,788,260 issued, or of application Ser. No. 494,201, the alleged division thereof.

While the "preheating patent" (1,967,195) states on its face it is a division of 494,201 which is in turn a division of 159,473, such statement is clearly erroneous.

Patent Office rules 35 to 37 and 41 and 43 inclusive,* clearly define what must be done to obtain a valid divisional patent. The record shows Warth did not comply with those rules or even attempt to do so.

Petitioner's brief states (p. 7) that Ser. 494,201 (the application for strip material) was filed as the result of a Patent Office requirement for division in application for patent 1,788,260 and cited page 1250 of the record. We submit that the record does not justify the conclusion drawn by petitioner.

While it is true that the Office required division, the letter calling for same, referred to in plaintiff's brief and appearing on page 1250 of the record, required division between the adhesive material *per se* claimed in application 159,473 (Pat. No. 1,788,260) and the method claims in said application and **most distinctly it did not call for any division between the different steps involved in the heating method claims.**

Application 494,201, as filed, did not even comply with this requirement for the reason that the claims in said alleged divisional application were not directed to an adhesive *per se,* as were the claims in 159,473, the matter in regard to which the Patent Office insisted upon division. The claims were directed to an adhesively coated *strip.* It is true that the specification contained a description of the steps in the heating method, including preheating, but they were merely inserted as describing the way in which the strip material,

* See Appendix, pages 56/7.

claimed in that application, was to be used and were not made the basis of any claim.

In other words, in the application Ser. 159,743 (Pat. 1,788,260) the Examiner called for division between the method of applying the adhesive strips and the adhesive to be applied to the strip. No division was required in regard to any part of the *heating* method and the alleged divisional application as filed, which contained exactly the same disclosure as the parent patent, practically without change, not only did not claim any part of the heating method, but also failed to make the claims for an adhesive *per se* which had been taken out of the parent application pursuant to the requirement for division. **It claimed a third and distinct invention viz: strip material.** It is quite evident, therefore, that it cannot be considered a true division of application 159,473; certainly not the division called for by the Office action appearing in the Record. Serial 494,201 was ultimately abandoned as appears on pages 5/6, *supra*.

On April 4th, 1933, two years and five months after the filing of this application 494,201 for strip material, and two years and three months after the grant of patent 1,788,260 (the original of reissue 19,117, the patent in suit) and six years and three months after filing the application of Jan. 7, 1927 (Ser. 159,743) containing the preheating disclosure, Warth filed the application which resulted in Patent No. 1,967,195, inserting therein preheating claims, and was allowed not only the filing date of application 494,201 for strip material, but that of the original application.

Pursuant to Rule 43 of the Patent Office, Warth, in the amendment to application 159,473 cancelling the adhesive claims in response to the requirement for division, stated they were cancelled for that purpose, thus reserving the right to file a true divisional application to obtain *such claims* for the adhesive *per se* (p. 1251, Rec.).

This, of course, was not notice to any one inspecting the file that a divisional application was intended in regard to

any of the heating steps, claims for which were retained in the parent application. It is clear that Warth did not follow the rules of the Patent Office referring to divisional application.

It follows that neither petitioner's argument nor the decisions relied on by him on the question of divisional applications have the slightest application to the facts of this case.

Mere disclosure of invention in the Patent Office without a claim for the subject of the invention does not permit a patentee to subsequently claim the invention long afterwards.

It is the position of petitioner that because it had continuously on file an application disclosing the preheating step, although without any claims therefor, it was entitled to make the claims for that step and get the date of January 7th, 1927 when the application first disclosing that preheating step was filed and consequently there was no abandonment. The District Court so found and in support of its holding cited the case of *Writer* v. *Kiwad*, 63 F. R. (2d) 259. (Petitioner refers to that case on page 8 of its brief.)

With the utmost deference to the District Court, it is submitted that the facts in the cited case are in no way analogous to the facts in the case at bar and the case has not the slightest bearing. In the *Writer* v. *Kiwad* case Kiwad filed an application in 1926 and claimed the invention in issue, but pursuant to a requirement of division, cancelled the claims, the drawing and descriptive matter in 1927. The Writer application was filed in November, 1928 and matured into a patent in August, 1929. Kiwad did not file his divisional application until December, 1929 after his attention was called to the Writer patent. The interference was declared on March 18th, 1930.

It will be seen that the case is entirely and radically different from the case at bar for the reason that Kiwad's parent application had not matured into a patent before his divi-

sional case was filed. The claims in the Kiwad parent application were not allowed until April, 1930, four months after the filing of his divisional application (p. 264).

The Circuit Court of Appeals in the case at bar followed what we understand to be the well settled rule, viz., that a divisional application to be availed of must be for the same invention and must claim it. The Circuit Court of Appeals said (p. 1837, Rec.), in referring to Warth's application for strip material Ser. 494,201:

> "Previously, on November 7th, 1930, Warth had filed a divisional application No. 494,201 to which he had transferred the preheating method; it claimed only the spot material strip as an article of manufacture. As we have previously shown, Warth's patents Nos. 1,788,260 and re-issue 19,117 contained no claims broad enough to cover preheating. Hence there was no claim for the preheating method on file in the Patent Office from December 3rd, 1930 until April 4th, 1933 when Warth applied by his second divisional application for the preheating patent."

It would seem elementary that a man who makes an invention should assert his right to that invention from the outset and take all the steps the law allows to protect it. This Court said in the case of *Milburn Co.* v. *Davis, etc.,* 270 U. S. 390 at page 401:

> "he is not an inventor in the sense of the statute unless he makes a claim."

In the case of *Jones* v. *Larter,* 1900 C. D. 111; 92 O. G. 383, the Commissioner of Patents said at page 115:

> "The presumption of dedication to the public by disclosure in a patent may, it is true, under certain circumstances be overcome by having a concurrently pending application claiming it; but *I know of no authority* for holding that it is overcome *by an application which does not and was not intended to claim it,* merely because the claims are inserted therein long after the patent on the other case issues."

The Commissioner in his decision cited:

James v. *Campbell,* 104 U. S. 356, 382;
Miller v. *Brass Co.,* 104 U. S. 350;
Mahn v. *Harwood,* 112 U. S. 354.

That case (*Jones* v. *Larter*) was followed and quoted from in the case of *Union Typewriter* v. *L. C. Smith & Bros.,* 173 F. R. 288, 297, affirmed by the C. C. A. 3rd Cir. in 181 F. R. 968.

It has been pointed out that Serial No. 494,201 was for Bottle Cap Spot Material, an article of manufacture, the original claim and subsequent claims were all directed to the strip material. There was *never any claim for a method of any kind in that application.*

In the case of *Ex parte Stimson,* 1916 C. D. page 20; 226 O. G. 699, the Commissioner of Patents said:

> "It appears from the remarks accompanying the amendment that when the application was prepared the process claims were deliberately omitted. The inventions *are so widely different* that it would be necessary to support the process claims by a supplemental oath.
>
> "No reason is seen for permitting an applicant to nullify an election deliberately made and after the application has been prosecuted to an allowance *on one invention present claims for an entirely different invention even for the purpose of interference.*"

After a patent has once issued, a patentee cannot subsequently file another application and call it a division of the issued patent.

In the case at bar, Patent 1,788,260 (the original of reissue 19,117 in suit) issued on January 6th, 1931. The "preheating method" patent 1,967,195 in controversy purports to be a division of that application. The application for the "preheating method" was not filed until April 4th, 1933, more than two years after the issuance of Patent 1,788,260.

The question is thus presented whether after a patent has once issued an application filed subsequent to the issuance can be considered a division and obtain the date of the parent application.

The question is one that, so far as we have been able to ascertain, has not been squarely passed upon by this Court.

It would seem on principle that after a patent issues for an invention, the inventor should not be allowed to file an independent application as was done here, and obtain the filing date of the original. It would seem that such practice might tend to indefinitely extend the monopoly.

The decisions of the lower courts and of the Patent Office seem to be clearly against such practice. In the case of *Gladding-McBean Corp.* v. *N. Clark & Sons,* 16 F. (2d) 50, (C. C. A. 9) two patents to McBean were involved. The first, No. 1,184,254 was applied for May 17th, 1915, issued May 23rd, 1916 for a mold or die for manufacturing roofing tiles. The second, No. 1,289,492, applied for January 8th, 1917, issued December 31st, 1918 was for a process of making tiles shown in the first patent and for the tile itself as an article of manufacture produced by the first patent. The Court held the second patent void and said (p. 51):

> "In the second patent, that for the method and for the article, the patentee stated his purpose to be to enable the tiles to be made economically and in quantities, under such conditions that sagging or warping while the material is in the plastic state is overcome. The drawings in the second and first patents, and the descriptions of the process and products are very similar. In the first patent, however, although the process and article produced were described, McBean only claimed the die. The result is that the process and the article became dedicated to the public, and the second patent is void, unless he filed a divisional application for the method and product, *while the original application was pending and before patent thereon was issued.* The rule is general and well established that a patentee cannot include in a subsequent patent any invention embraced or disclosed in a prior one granted

> to himself. By his own act he has made it public property. Mahn v. Harwood, 112 U. S. 354, 5 S. C. T. 174, 28 L. Ed. 665."

In *re Spitteler* and *Krische*, 1908 C. D. 374, a patent had issued and after its issue it was sought to obtain its date for a divisional application on matter which was disclosed in the original patent as filed. The Court of Appeals of the District of Columbia said (p. 376):

> "But having amended that application so as to conform to the ruling of the Examiner, it was merged and the patent issued thereon. After that there was no application pending in the Office as a foundation for a division. The proceeding having been closed by the issue of the patent, there was nothing to be continued. The rule which permits a divisional application to relate back to the filing date of the original which also discloses its subject matter, as long as it remains open in the Patent Office, is a very liberal one that sometimes works hardship upon intermediate inventors, and it ought not to be extended to cases not clearly within it."

The case of *Wainwright* vs. *Parker*, 1909 C. D. 379, 142 O. G. 1116, is quite similar to the facts disclosed by the present record. There an application as originally filed disclosed four different species.

Claims sufficient in scope to cover all were originally included. After repeated objections the application was limited to one of the species and the drawing, specification and claims were amended, without appeal, to eliminate all reference to the device involved in the interference.

The application was allowed and went to patent. Four years afterwards the applicant filed the application which became involved in interference and sought to get the date of his original application. That was denied by the Court of Appeals and it said in its opinion (p. 380):

> "His original application having eventuated into a patent, there was nothing left pending before the Patent Office upon which it could act, or to which the later application could attach."

To the same effect are the following cases:

Conover v. *Downs*, 35 F. R. (2d) 59;
Model Bottling Machinery Co. v. *Anheuser Busch Brewing Assn.*, 190 F. 573 C. C. A. 8th Circuit;
Hayes-Young Tie Plate Co. v. *St. Louis Transit Co.*, 137 F. 80.

The case of *Overland Co.* v. *Packard Co.*, 274 U. S. 417, was cited by the District Court in its opinion and is relied on by petitioner in its brief here. It is submitted that the situation disclosed in that case is so radically different from that in the present case that *Overland Co.* v. *Packard Co.* has absolutely no application.

In that case there were two questions certified to this court. The first one was whether the applicant who cancelled a claim which was finally rejected on May 20, 1911 abandoned such claim or estopped himself from thereafter seeking it through a new application. The claim appeared in an application filed on Sept. 6, 1901 and the patent issued on Jan. 21, 1913. The claim was cancelled on May 17, 1912. The applicant cancelled the claim, stating it was his intention to file a divisional application, and, less than four months after the cancellation, the claim was filed in a divisional application before the parent patent issued in 1913.

This court answered the first question in the negative. It is true that the court did state that after an applicant had cancelled a claim the Commissioner of Patents might have refused to accept it in another application because the cancellation was made without the consent or suggestion of the Office, but the fact that the Commissioner in the exercise of his discretion did permit a new application was a waiver of his right to refuse to accept it, and the patent issued thereon was therefore valid. The court in its decision cited several cases, on pages 420 and 421 of its opinion, upon the subject of the application of the principle of *res adjudicata* to proceedings in the Patent Office which sustained its conclusion.

The second question certified to the court in the *Overland* case was whether a patentee should be penalized for waiting the full statutory time before amending his application. That question was also answered in the negative.

It is true that in *Overland Co.* v. *Packard Co*, a disclosure of the subject of the claim in issue was made in an application filed by the patentee on August 25, 1899 which resulted in a patent on July 13, 1900. In that application the patent office required division and the applicant cancelled the description and drawing which supported such claims and the patent issued in 1900 merely covered the remaining claims. On September 6, 1901 he filed another application not a divisional, disclosing and claiming the subject matter in the suit. There was thus an interval of fourteen months between the issuance of the patent in July and September 6, 1901 on which the patent in suit was based. As to that phase of the case, it would seem to resemble somewhat the case at bar. The differences, however, are that Cowles, the inventor in the *Packard* case, promptly indicated an intention to claim and protect his invention instead of deliberately abandoning, the same, to obtain a restricted patent as Warth did. The 1901 application was filed 14 months after the issue of the first patent applied for in 1899, and Cowles stated, when cancelling the claims in the second application, that he intended to file a division claiming the subject matter, which he did within 4 months. **In the meantime no intervening rights had vested in any third party.**

The Alleged Inadvertent Issue of Johnson Patent No. 1,852,578.

Petitioner on pages 8/9, 34/5 of its brief says the issue of the Johnson patent was an inadvertence on the part of the Patent Office and an interference should have been declared by the Patent Office between the application for the Johnson patent filed November 26th, 1929, and the application for the parent Warth patent No. 1,788,260. This is

the first time that petitioner has raised that issue. In all its various briefs before the District Court, the Circuit Court of Appeals, and its briefs on the application for the writ of certiorari, petitioner never raised this point.

The Record shows clearly, however, that there is no foundation for this contention and that the Johnson patent is properly and regularly issued.

Petitioner has overlooked Rules 93 and 94 of the Patent Office which provide that interferences are instituted only between applications "claiming substantially the same patentable invention and may be instituted as soon as it is determined that *common patentable subject matter is claimed* in a plurality of applications, etc."

The certified copy of the file wrapper of the Johnson patent put in evidence by petitioner (Ex. 87, p. 676, Rec.) shows that it was filed on November 26th, 1929 and the first Office action therein is dated September 10th, 1930 (p. 715, Rec.) and stated that certain claims, including the three claims in controversy "are allowable as at present advised."

All of the claims in Serial No. 159,743 (the application resulting in Patent No. 1,788,260) had been finally rejected by the Primary Examiner on February 4th, 1930 (p. 1256, Rec.). An appeal was filed to the Board of Appeals by applicant's attorneys on July 18th, 1930. Consequently, when the Examiner in September 1930 rendered his first action on the Johnson patent there were no allowable claims pending in the Warth application. **Certainly the Examiner could not be expected to declare an interference between an application and another application in which the claims had been held unpatentable by the Office, and on which an appeal was pending on the question of patentability.**

As has been pointed out the description and claims on appeal in the Warth application for the preheating step were cancelled and abandoned on December 3rd, 1930.

The next Office action in the Johnson application is dated July 30th, 1931. At that time the Warth patent had issued without any disclosure or claims for the preheating method.

Certainly, the Examiner would not be justified in declaring an interference between an application and an issued patent, the file of which showed that the matter claimed by the second applicant had been deliberately and voluntarily cancelled and eliminated from the first application without any notice of reservation of its being claimed in another application. **In other words, when the Examiner in charge of the Johnson application made his interference search, there were no method claims of any kind on file in Warth's applications upon which Petitioner relies for continuity. Neither were there any method claims in application numbers 360,895 or 452,596 for bottle cap and method of making same referred to on page 13 supra of this brief.** On the point that no interference should have been declared attention is called to *Gold* vs. *Gold*, 34 App. D. C. 229, Com. Dec. 1910, page 269.

It is quite true that in his action of July 30th, 1931 the Examiner rejected claim 35 of Johnson on the Warth Patent No. 1,788,260. An inspection of that claim 35, however, (p. 713, Rec.) shows it contained the statement, "then placing the linings and the caps under heat and pressure to render the adhesive viscous and effect an intimate contact between the linings and pads." That claim was, of course, broad enough to include claims cancelled by Warth in order to obtain the Warth Patent No. 1,788,260 and for that matter was broad enough to read on the patent to McManus No. 1,402,780 and the patent to Alberti, No. 1,401,300 mentioned in the decision of the Examiner of Interferences quoted on page 50 of this brief, *infra*.

It is significant that the Examiner allowed the three claims in controversy over the disclosure of the issued patent to Warth No. 1,788,260.

Publication.

Petitioner states on page 11 of its brief that inasmuch as the disclosure of the preheating step and the claims therefor had been cancelled during the prosecution of Patent No. 1,788,260, obviously, they did not appear in that patent when

it issued on January 6th, 1931 and, consequently, there was no publication of that matter.

It is, of course, true that the cancelled matter did not appear in the issued patent. It is equally true, however, that when a patent issues the entire file wrapper is open to the public. It is a matter of public record.

Ludlam Steel Co. vs. *Terry,* 37 F. R. (2) 153 at 165.

This Court said in the case of *Mahn* vs. *Harwood,* 112 U. S. 354 at page 362:

> "Whenever it is manifest from the patent itself, compared with the original patent and *cognate documents of record,* or from the facts developed in the case etc."

To the same effect is the case of *James* vs. *Campbell,* 104 U. S. 356 at page 368.

Anyone looking at the file of Patent No. 1,788,260 immediately after it issued on January 6th, 1931 would see that the preheating disclosure and claims broad enough to include same had been cancelled and under the authorities we have cited on this brief would naturally assume that that matter and any claims therefor were abandoned by the inventor and dedicated to the public. As appears from the Appendix on page 57 of this brief *infra,* Rule 43 of the Patent Office requires that when two or more applications are pending relating to the same invention all showing, but only one claiming the same thing, the application not claiming it must contain reference to the application claiming it. There is no reference made to any co-pending application either in the file of the application for Patent No. 1,788,260 nor in Serial No. 494,201.

This Court said in the case of *Milburn Co.* v. *Davis etc. Co.,* 270 U. S. 390 at page 402,

> "A description that would bar a patent if printed in a periodical or in an issued patent is equally effective in an application so far as reduction to practice goes."

POINT II.

Intervening Rights.

Petitioner says there are no intervening rights and argues that the case is controlled by the decision of this court in *Chapman* v. *Wintroath* because Warth copied the claims of the Johnson patent within two years of its issue.

Petitioner also says that the District Court found there were no intervening rights because it found that the machines purchased by respondent from Johnson from 1928 up to 1933 had no preheating device, and, inasmuch as the decision of the Circuit Court of Appeals did not in so many words expressly state that it reversed the finding of the District Court, respondent is precluded in this court from referring to the evidence on the subject.

In support of this contention, ~~respondent~~ petitioner relies upon a decision of this court in the case of *Adamson* v. *Gilliland*, 242 U. S. 350. That case does not support petitioner's contention but is authority for the proposition that this court will examine a record, even when there were unanimous findings by both the lower courts.

The Court of Appeals expressly reversed the District Court on its finding as to abandonment. It expressly reversed the District Court on the question of infringement of the heated plunger patent (Reissue 19, 117). The situation, therefore, is that of the four judges who have passed on the case, two have held in favor of petitioner on the patents in controversy and two in favor of respondent.

It would seem clear, therefore, that under such circumstances respondent is justified in asking this court to look into the record sufficiently to see whether the findings of fact by the District Court are supported by the evidence. *Berlin Mills Co.* v. *Proctor & Gamble Co.*, 254 U. S. 156; *Thomson Spot Welder Co.* v. *Ford Motor Co.*, 265 U. S. 445.

Respondent contends that the finding of the District Court (p. 1803, Rec.) that

> "The machines purchased by defendant from Johnson in 1928, had no preheater, and I am convinced that defendant made no further purchase from Johnson until 1933, therefore the defendant has not proved any use of the preheating method, to anticipate the filing date of the first divisional application Nov. 7th, 1930 or the filing date of the second divisional application April 4, 1933"

is not only unsupported by the facts in the record but is clearly contrary to the facts in the record, some of which are documentary and others are impliedly, if not expressly, conceded by petitioners own witnesses and statements in its brief in this Court.

The statement that "defendant made no further purchase from Johnson until 1933" is shown to be incorrect from the following documentary evidence. Respondent's Exhibit Q (pp. 881/2, Rec.) consists of bills from Johnson to respondent dated September 17th, 1928, December 19th, 1928, March 30, 1929 and April 30, 1929 for spotting machines. The words in those bills "extra head, roll feed" show that the machines had the preheating device (XQ.'s 479/87, pp. 260/61, Rec.).

Even if the machines did not have the preheating device, the purchase of those machines shows the finding of the District Court above quoted that respondent *did not purchase any machines* from Johnson between July 1928 and 1933 is clear error.

It appears from the cross examination of Johnson by petitioner's counsel, pages ~~2868~~ and Petitioner's Exhibits 36/7, pages 609/10, Record that Johnson had made and sold in April, 1928 a center spot machine for the Armstrong Cork Co. which proved unsatisfactory; that it was returned by that company as being unsatisfactory because the tinfoil center spots would not stick and Johnson altered it by tak-

ing the heat out of the cutting punch and preheating the cork. On this point we quote XQ's 115 to 119, found at pages 173 of the Record of Johnson's testimony, as follows:

> "XQ115. When you say in this letter that you are going to see what you could do in regard to not having the tin-foil disc stick to the punch, do you recall what that was? A. Yes, I sure do.
>
> XQ116. What was it? A. I took the heat out of the cutting punch altogether and installed two heaters in front of it, and also a space heater I installed before the tin-foil disc was cut and inserted. And that kept the cutting punch cold.
>
> XQ117. And that was done after you wrote this letter of October 5th? A. That was done at that time, you see I had that machine practically completed at that time.
>
> XQ118. You say here you were going to see, 'and I now have to see what I can do in regard to not having the tin-foil disc stick to the punch.' A. Well, that is the word I suppose I used, I was working on it at this time.
>
> XQ119. It was about this time, October 5th, that you put on this pre-heater? A. Yes."

Attention is also directed to the petition for public use proceedings instituted by Johnson during the Warth-Johnson interference and the affidavits attached thereto. Those public use proceedings comprise a petition and affidavit by Johnson, pages 901-9, Record, an affidavit of John O. Seifert, the attorney who prepared the patent application for the Johnson patent, and is to the effect that in January, 1929 he called at Johnson's place and saw in operation a machine having the preheating feature and that the drawings of the application for the Johnson patent as filed correctly described the machine he saw in January, 1929. That affidavit is corroborated by the affidavit of Alfred Krafft, pages 917-18, Record, to the effect that he called at Johnson's place of business in January, 1929, saw the machine and made the drawings of the application of the patent therefor. The

affidavits of Rudolph Fusco, John W. Larson and Charles W. Molander, employees of Johnson, are to the same effect. There is an affidavit from Nicholas Corsi, who is associated with an independent manufacturer, which states that during the month of October, 1930 a firm, the Arrow Bottle Cap Corp., purchased a machine from Johnson having the feature of preheating the cork and that it was made in accordance with patent 1,852,578 to Johnson.

Before the termination of the interference, and after the purchase of the Johnson patent by petitioner, the public use proceedings were terminated and the orginal petition and affidavit were withdrawn from the Patent Office by stipulation of the parties, page 165, Record. Petitioner itself offered in evidence a certified copy of the file history of the Johnson patent showing it was filed on Nov. 26th, 1929.

It is most improbable and almost impossible to believe that if Johnson found the heated cutting punch impractical and changed to preheating the cork, as shown in his patent, as early as October, 1928 and took steps as early as January, 1929 to apply for a patent, he would have sold to respondent in September and December, 1928, and March and April, 1929, machines which did not have the preheating feature.

The documentary evidence, including petitioner's own exhibit 36/37, the cross-examination of Johnson showing that he abandoned the heated plunger at least as early as October, 1928, the bills to respondent from Johnson from September, 1928 to April, 1929, show beyond question that the Court was in error in holding that none of the machines purchased by petitioner from Johnson between 1928 and 1933 had the preheating device and the decision is clearly against the weight of evidence.

Respondents evidence further shows Test Cohn, pages 214 and 258/9, Record; Rasmussen, page 281, Record; Eisen, page 294, Record; Ketterer, page 200, Record; Respondent's Exhibits NNN to TTT, pages 1519/68, Record, that between Aug. 1928 and the trial of the case Respondent had made by

the preheating method approximately one million gross of caps having a metal foil center spot secured by gutta-percha to one customer, the Goetz Brewery and large quantities to other companies (p. 237, Rec.). All the foregoing evidence shows a clear intervening right on the part of Respondent.

In addition to the intervening rights acquired by respondent by the purchase and use of machines purchased from Johnson in 1928 and 1929, having the preheating method, attention is called to patent #1,921,808 (p. 596, Rec.) issued to Benno Cohn, secretary of respondent. That patent discloses and claims a method of making caps wherein the cork disc is preheated and the cork disc and center spots are all inserted in one machine.

The application for that patent was filed July 20th, 1932, nine months before Warth filed his application on April 4th, 1933 for the alleged divisional preheating method patent in suit.

Petitioner knew in 1930 that Respondent was making and selling Center Spot Caps.

Furthermore as showing intervening rights of respondent and its good faith attention is directed to respondent's Exhibit PPPP, page 1605, Record, a letter from Respondent to Petitioner dated October 10th, 1930, protesting against the representations of Petitioner's salesmen to the effect that the sales of center spot caps by respondent was an infringement of Petitioner's patents. The reply of Petitioner is found at page 1605, Record and is to the effect that no such further statements would be permitted by its salesmen. Respondent relied on this letter of Petitioner and showed it to its customers as proof of the fact that Respondent was "not infringing on anybody's rights" (p. 311/12 Rec.) and in reliance thereon purchased four more machines from Johnson in 1933 (Respt.'s Ex. R, p. 883/6, Rec.).

Petitioner had knowledge in October, 1930, that Respondent was engaged in the manufacture and sale of center spot

caps. It was Petitioner's duty to have then ascertained what method Respondent was using. The Record does not show that there were any manufacturers of center spot machinery other than Johnson and Nagy who had made center spot attachments in 1916 and 1921 (p. 139 and 142/3) for other manufacturers of center spot caps. After that and in Dec. 1930 Petitioner cancelled all reference to preheating.

Petitioner's Exhibit No. 84 (p. 659, Rec.) is a letter dated March 21st, 1933 from petitioner to respondent offering to give respondent a license under five patents, three of which have been held invalid by the courts below in this case.[1] One was not involved in the litigation and the other one was patent 1,788,260, the original of the re-issue. Respondent declined to take a license under these patents. Various interviews were had between the officers of petitioner and respondent looking to some amicable adjustment, several conferences were had between the officers of the respective parties and the officers of the petitioner called at respondent's plant in April and August, 1933 (pp. 222/3, Rec.). The respondent declined to sign a license agreement which was signed by all the other manufacturers in the trade and provided for a fixing of the price by petitioner herein (pp. 1599-1601, Rec.) on the ground that it did not use the subject matter of some of the patents and on the further ground that it had its own patent for a method of manufacture (p. 309, Rec.). That patent is No. 1,921,808 issued to Benno Cohn, application filed July 20th, 1932, patent issued August 8th, 1933. That patent describes and claims the preheating of the cork the same as in the Johnson patent and in the preheating method patent in controversy and differs from the Johnson and Warth patents in one very important particular and that is in the Cohn patent the cork disks are placed in the metal shell and the center spots are applied all in one machine, whereas in the Johnson and Warth and all

[1] That was before the filing of the Warth alleged divisional application on Apr. 4th, 1933 resulting in the preheating method patent.

other prior art machines and patents for applying the center spot, the cork cushion disk is secured in the shell in one machine and the center spot is put on the assembled crown in a different and separate machine.

On August 8th, 1933, the vice-president of petitioner and its counsel visited respondent's plant in another attempt to settle the negotiations (p. 309, Rec.). During that visit they were shown defendant's plant in operation. They saw respondent was using the machine of the Cohn patent which had the preheating device. They were informed and knew that respondent had bought its machines from Johnson. They were given samples of the bottle cap strip material thermoplastically coated which respondent was using and were given caps made by respondent (p. 223, Rec.).

Petitioner's vice-president Fusting testified that petitioner did not know of the use by respondent of a Johnson machine or method until his visit to respondent's plant (p. 521, Rec.). Petitioner could have at any time after the date of that visit on August 8th, 1933, brought suit for infringement on claim 1 of Patent No. 1,788,260 which is claim 1, without change, of the re-issue heated plunger patent in controversy. It did not do so, however. On January 23rd, 1934 it filed its application for re-issue of 1,788,260. It said nothing about and made no attempt to insert claims broad enough to cover the preheating step. On December 12th, 1933, after knowledge that respondent was using the machine of the Johnson patent, petitioner purchased the Johnson patent and took an assignment thereof. It made no attempt to bring suit until after the issue of its patent No. 1,967,195 for the preheating method on July 17th, 1934. The present suit was started in September, 1934.

In *Railway Co.* vs. *Sayles,* 97 U. S. 554, this Court held that an original specification could not be so enlarged by the filing of a new application, based upon an earlier application, as to appropriate that which had in the meantime gone into public use, or where there has been an adverse intervening right.

Petitioner's Laches Began in March, 1929 When it Bought From Johnson, an Independent Manufacturer of Assembling Machines, Five Machines Constructed in Accordance With Johnson Patent 1,852,578.

There is no dispute that petitioner bought five machines from Johnson between February and July 31st, 1929, the invoices, bills of lading, and correspondence relating thereto are found at pages 888-900 of the Record.

This is admitted in petitioner's brief (p. 22). It was so found by the District Court (p. 1802, Rec.) and held that their purchase by petitioner did not affect its rights covered by the application of January 7th, 1927 for Patent No. 1,788,260 and cited authorities in support of that proposition.

Petitioner refers to this on page 22 of its brief and states:

> "Respondent did not contend before the lower courts, nor did either Court find, that petitioner's admitted use of the preheating invention for some years prior to the filing of the Warth divisional application invalidates the patent."

Petitioner is in error in making this statement. Respondent contended most strenuously in the District Court and the Court of Appeals that the purchase of these five machines from Johnson by petitioner in 1929 clearly invalidated the alleged divisional patent for the "preheating" method. *If respondent had not so contended, the District Court would not have gone out of its way to make the finding we have referred to at the beginning of this chapter.* The Circuit Court of Appeals necessarily made no express reference to the subject in its decision for the reason that such reference was unnecessary in view of the fact that the Court of Appeals held the alleged divisional patent invalid by reason of laches and abandonment.

The District Court found, as we read its decision, and petitioner expressly admits (p. 22 of its brief) that these machines shipped from Johnson to petitioner in 1929 had the preheating device. The error in the finding of the District Court lies in the statement that the machines were built on "special order" for petitioner. We assume from that statement of the District Court that it meant petitioner gave Johnson instructions to build the spotting machines with the preheating device. That finding is completely contradicted by petitioner's own acts and the correspondence had with Johnson.

It is clear beyond all question that machines used by both parties are radically different in mechanical construction. The District Court so found (p. 1791, Rec.). That the machines are different is emphasized by the fact already referred to (p. 7, Br., *supra*) that when Warth copied the Johnson method claims for interference purposes, he did not copy the apparatus claims. He could not do so, because he never invented the apparatus of the Johnson patent. It is admitted (p. 32, Petr.'s Br.) and appears in the testimony of Johnson (p. 160, Rec.) that Johnson was an independent manufacturer of assembling machinery and had been so engaged for about thirty-three years. He "designed a great deal of the machinery *which is now in use in this Crown industry*" (p. 176, Rec.). That the machines were bought by petitioner after conversation and correspondence with Johnson as to the machines is shown by petitioner's letter of February 27th, 1929 (p. 891, Rec.) which states:

> "Referring to your conversation and correspondence with our Dr. Warth, would suggest that you send us *on approval* the machine for adhering the gutta percha lining to the tin foil. Also the machine for cutting the tin foil and fastening same to the cork washer on finished crowns."

The testimony of petitioner's witnesses Goebel (p. 413, Rec.) and its vice-president Fusting (p. 521, Rec.) admits the purchase of these machines. Both of these witnesses

say the machines were purchased for use in its Canadian plant; that they were shipped from Baltimore to be "tuned up" and then shipped to Canada (p. 423, Rec.).

Yet Petitioner alleges on page 9 of its brief that there was no necessity for Warth to claim the preheating method until the Johnson Patent came to his attention.

A most significant feature of the transaction is that petitioner did not attain its high production of 520 caps per minute until 1930 after it had bought the Johnson machines (p. 413, Rec.).

The testimony of Fusting (p. 521, Rec.) petitioner's vice-president is to the effect that petitioner always built its own spotting and assembling machinery and the excuse for buying these five machines from Johnson was that petitioner's plant was crowded with work at that time.

We have already adverted to the evidence showing that at least as early as October, 1928, Johnson had discarded the method of heating the plunger and adopted that of preheating the cork and that while his application was not filed until November 26, 1929 his attorney and the draftsman had seen a full sized operating machine for the method of preheating the cork in January, 1929.

It is submitted therefore that petitioner had complete knowledge of the preheating method of Johnson's machine, and quite apart from the question of abandonment by proceedings in the Patent Office, its laches began to run when it obtained knowledge of Johnson's preheating method and the purchase of these five machines from him between March and July, 1929.

Warth v. Johnson Interference 66,201.

This interference was really an ex parte proceeding and was not a bona fide interference. Obviously this Interference was instituted after Petitioner purchased the Johnson patent for the sole purpose of abrogating the right of respondent to use the machines it had purchased from Johnson in

Page Tightly Bound

the years 1928 and 1929. Respondent by the purchase of those machines from Johnson before the issue of his patent had acquired a license under the Statute Sec. 4899 to use those and its right could not be divested by any subsequent act on the part of Petitioner. Especially as Warth did not contend he invented the apparatus, *Keystone Type Foundry* vs. *Fastpress Co.*, 272 F. R. 243; *Dable Grain Shovel Company* v. *Flint*, 137 U. S. 41; *DeForest Radio Telephone Co.* v. *United States*, 273 U. S. 236.

Johnson's preliminary statement (p. 1765, Rec.) alleges a date of conception in the fall of 1925. No proof of the facts alleged therein are put in evidence, for, as pointed out at pages 7/8, *supra*, after the interference was declared, and a motion made by Warth to shift the burden of proof to obtain his filing date of January 7th, 1927 had been denied, the petitioner purchased the Johnson Patent and after its purchase the attorneys for both sides made a stipulated record found at pages 1615/27 of the Record which did not contain the preliminary statement of either party. Warth's preliminary statement is not in evidence. It was on that record that the Examiner of Interferences rendered a decision (p. 660, Rec.) reversing his prior holding and awarding priority to Warth.

Under Rule 94 of the Patent Office, petitioner could have and should have decided whether to take out the claims in the Warth application or retain the Johnson patent which it owned. **Instead of doing that, it made up the stipulated record, after its purchase of the Johnson patent, in order to obtain the filing date of Warth for the claims in issue which was prior to that of Johnson with the undoubted purpose of abrogating rights which respondent had acquired to the use of the Johnson machine by the purchase of such machines from Johnson.**

The District Court held that petitioner could not elect between the Johnson patent and the Warth application because it did not have title to the Johnson patent (p. 1801, Rec.). The record shows that petitioner did have title to the Johnson patent before the stipulated record was made up

because it purchased it on December 12th, 1933 and on the same day issued a license to Johnson saying petitioner was the owner of Johnson Patent 1,852,578 (pp. 923-925, Rec.).

Petitioner now contends (p. 32 of its brief) that Johnson derived his knowledge of the invention from Warth. The testimony of petitioner's witness McManus is that it was April or May, 1928 (p. 348, Rec.). Goebel said it was March or April (p. 375, Rec.) and another witness *for petitioner*, Volpe, said it was April or May (p. 360, Rec.). There was no contemporaneous documentary evidence offered substantiating any date. If it was either March or April, it is inconceivable that Johnson would sell a machine to the Armstrong Cork Co. on April 24th which did not have the preheating device, as appears from petitioner's Exhibit 37 (pp. 609/10, Rec.) previously referred to. It is that machine, the one sold to the Armstrong Cork Co. that Johnson fixed up in October, 1928, as appears from his testimony quoted on page 28 of this brief, *supra*.

Johnson was scrupulously careful of the rights of others and would not knowingly make a device or take any steps that would involve him in litigation as shown by *petitioner's own* Exhibit 37 (p. 609, a letter from Johnson to the Armstrong Cork Co.) which states in part on page 610:

> "The price on the two machines together is $1500., but I have heard that McManus claims to have a patent on sticking the tin foil to the corks with adhesive. * * * but I want to find out first as I do not want to infringe on anybody's patents.
>
> "I could send you this machine with the understanding that if it should be patented I would have the right to call this machine back or if you would wait until I got the copy of the patent."

It will be noted that letter is dated April 24th, 1928. If the testimony of Goebel who said that Johnson's visit was in March or April, 1928, or Volpe, who said it was April or May, is correct, then the letter from which we have quoted

which is dated April 24th, 1928 indicates two things. The first is that Johnson has stated in his letter that he would not willingly appropriate anyone else's invention; and the second thing is that it renders petitioner's contention that Johnson derived knowledge of the preheating from petitioner utterly unfounded for it cannot be assumed that Johnson an experienced builder of assembling machines, would have shipped to the Armstrong Company in April, 1928 a machine which did not have the preheating device.

Petitioner in his brief having raised the question that Johnson, from whom respondent bought his machines, obtained his knowledge of the invention from a visit to petitioner's factory, it is only proper as bearing on the credibility of the witnesses for petitioner on that point and on their testimony bearing on the date of invention of the preheating method, to refer to the proceedings in the Patent Office showing the irregularity and misrepresentations made to the Patent Office by petitioner and the patentee Warth, and the concealment of material facts, not only in the two patents in controversy, but in some of the other patents upon which the suit was brought and which were held invalid by the Courts below.

One of the patents held invalid by both courts below is the Warth patent 1,899,783 which is for a bottle cap and method of producing same, the claims of which are for a center spot of hard varnished paper secured by gutta percha. Petitioner admitted in answer to interrogatories that it had been making caps with metal and paper center spots secured by gutta percha as early as 1917 (Int. 20; 27; 31/2; pp. 1589/91, Rec.). That is 12 years before application for that patent was filed. The record shows that in 1926 Warth filed an application for precisely the same thing, viz., Ser. 130,961, page 1731, Record and having the same disclosure and substantially the same claims as issued patent 1,899,783 (p. 1735/8, Rec.). That application was rejected by the Examiner as showing no invention over the art (pp. 1745/48,

Rec.) and the Board of Appeals affirmed that decision, page 1758, Record on the ground that the center spots were old and that "the use of elastic cement is, in our opinion, an obvious feature in attaching the disc". Apparently the Examiner who had charge of the application for patent 1,899,783 either overlooked the decision or at least he was not informed of the decision of the Board, for he granted the patent in spite of it. During the prosecution of that application, Warth made an affidavit in which he said, page 790, Record, after a statement of his difficulty in finding a suitable adhesive:

> "The only adhesive available at the time having these characteristics, I found to be gutta percha, or a mixture of gutta percha and other materials, making the adhesive essentially gutta percha."

When called as a witness, Warth admitted and petitioner's witness Goebel said the use of gutta percha as an adhesive for center spots was discovered by a chemist named Daly about a year before Warth entered the employ of petitioner, pages 472/4 and page 368. See also page 409, Record.

As to the patent to Warth, 1,899,782 for strip material, it was clearly shown to be old and the court so found, page 1781, Record and no appeal taken therefrom. That patent was used as a basis for a license agreement among various paper manufacturers (p. 965, Rec.) not to sell any strip material adhesively coated to any manufacturer of center spot caps who was not a licensee under the license agreement made with petitioner previously referred to found at (pp. 1597/1603, Rec.).

As to the heat and pressure patents, the method was disclosed in the abandoned application of Warth found at page 1737, Record, in which, after describing the affixing of the center spot to the cork disc by heat and pressure, he said:

> **"It is noted that apparatus for cutting and assembling spot centers is known in the art."**

POINT III.

The law applicable to re-issues and divisional applications.

We beg to refer to the language of this Court in *Webster Co.* v. *Splitdorf Co.* and particularly to the last sentence which is as follows (p. 471):

> "In other words, we follow in that respect the analogy furnished by the patent re-issue cases."

It will be readily seen that *Chapman* v. *Wintroath* which involved a divisional application only has no application to the facts in this Record for the reason that in *Chapman* v. *Wintroath* the parent case had not issued when the divisional case was filed as in the case at bar. Furthermore, in *Chapman* v. *Wintroath* the unclaimed disclosure of the subject matter of the claims was for the same invention, and there had been no voluntary cancellation of the subject matter of the divisional patent in order to obtain a patent. In the case at bar the disclosure relied on was in an application for an entirely different invention, viz., strip material, an article of manufacture, and no method claims of any kind were ever made in that application.

Divisional applications are not expressly sanctioned by the Statute. The practice of filing such applications is merely a matter of expediency, authorized by the Rules of Practice of the Patent Office (Rule 41) sanctioned by this Court in *Steinmetz* vs. *Allen*, 192 U. S., 543 (and other courts), and generally recognized by those dealing with patents. It might be said that the filing of divisional applications has been legalized by custom.

The practice in the Patent Office for many years has been to permit the filing of a divisional application at any time prior to the issuance of a patent upon the parent application.

When a patent has once issued, however, any correction or alteration therein must be by re-issue (R. S. 4916), otherwise

it must be dealt with strictly in accordance with the Statutes provided for this purpose.

This long established Patent Office practice was modified by the decision of the Court of Appeals of the District of Columbia in *Rowntree* vs. *Sloan*, 45 App. D. C. 207, which held that an inventor, during the pendency of his application, could not assert a claim for subject matter disclosed in said pending application in a divisional-application if he neglected to file such divisional application within one year from the granting of a patent to a third party, abandonment by laches being presumed because of the delay in asserting the claim.

In *Chapman* vs. *Wintroath*, 252 U. S. 126, this Court held that while an inventor might lose his rights to assert a claim by a delay in filing a division of a pending application, (the basis of the decision in *Rowntree* vs. *Sloan*) there was nothing in the Statutes to justify a fixed time of one year, and that by analogy to the two year public use and two year publication specified in R. S. 4886, a delay of two years was not such an unreasonable delay as would bar an inventor from asserting a claim derived from a patent issued to a third party.

In *Webster* vs. *Splitdorf*, 264 U. S. 463, the decision in the *Wintroath* case was amplified by an analogy with re-issue cases in which a broadened re-issue must be applied for within two years from the grant of the patent except where a further delay is accounted for and caused by special circumstances which show it to have been not unreasonable. See last paragraph of the decision on page 471.

We understand the settled law in re-issue cases to be that applications therefor, in the absence of special circumstances, must be made within two years from the date of issue *and that any bona fide intervening rights bar the same no matter when acquired.* *Ives* vs. *Sargent*, 119 U. S. 652; *Coon* vs. *Wilson*, 113 U. S. 268 at 276-7. That is, a patent may not be validly re-issued if said re-issue makes that unlawful which was previously lawful. *Coon* vs. *Wilson, supra.*

In the *Wintroath* case, in the *Webster* vs. *Splitdorf* case and in various reported decisions following these cases, the divisional application was always carved from a *pending application* for the same invention and the delay was predicated upon a patent issued to an independent inventor during the pendency of the original application and prior to the filing of the divisional application.

In the case at bar patent 1,788,260, the original parent patent, the date of which is sought by plaintiff, had *issued more than two years prior* to the filing date of the application for 1,967,195, the "preheating" patent. The Johnson patent had issued approximately one year prior to the filing of said preheating application, to say nothing of other rights which had intervened set forth at pages 26 *et seq. supra.*

The analogy between a divisional application filed during the pendency of its parent application for the purpose of interference with a patent issued to a third party, and a reissue application can readily be understood, but it is thought that this analogy is even greater, where, coupled with the issuance of a patent to an independent inventor, there has been an actual grant of a patent upon the original application upon which a divisional application is alleged to be based, because under such circumstances the divisional application is subject not only to the infirmities of an application carved from a pending application, but all those based upon the record of the proceedings in the Patent Office showing the limitations imposed by the Commissioner of Patents, and acquiesced in by the inventor as a condition precedent to the grant of the patent from which the divisional application is carved.

Unquestionably the effect of the claims in patent 1,967,195, was to make unlawful that which previously had been lawful to respondent, namely, the use of machines purchased in good faith from Johnson, or the use of the preheating method in any manner. Obviously, petitioner could not have accomplished this by re-issue of 1,788,260 (quite apart from the rule that a claim cancelled to obtain a patent may

not be reinstated by re-issue, or at all, *James* vs. *Campbell, supra*) because of the principles in regard to re-issue patents laid down in the cases previously cited herein.

It is apparent that Warth, or rather his assignee, is endeavoring to take advantage of the liberal attitude of the courts towards divisional applications to accomplish something which he would not be permitted to do by re-issue.

We submit, therefore, that the resemblance between the instant case and the reissue cases is marked, and much closer than that disclosed by the facts in *Webster* v. *Splitdorf, Chapman* v. *Wintroath,* or any of the other cases referred to in petitioner's brief. This would be so even if the application for patent No. 1,967,195 had been a true divisional application which as we have shown at pages 14/16 *et seq. supra,* it is not.

Without questioning the propriety of the statement in *Chapman* vs. *Wintroath,* appearing at page 137 of the report, quoted on page 14 of petitioner's brief, it should also be noted that this Court stated in *James* vs. *Campbell, supra,* referring to the conditions sought to be avoided by the filing of re-issue applications in lieu of new applications:

> "Patentees avoid doing this (filing a new application) when they can, and seek to embrace additional matters in a reissue, in order to supersede and get possession of the rights which the public, by lapse of time or other cause, have acquired in the meantime."

And also in *Leggett* vs. *Avery,* 101 U. S. 256,

> "The allowance of claims once formally abandoned by the applicant, in order to get his letters-patent through, is the occasion of immense frauds against the public."

POINT IV.

There is no proof of infringement of reissue 19,117 by respondent.

There is no proof in the record that respondent ever made a cap by the heated plunger (reissue patent) nor is there any reference in petitioner's brief to such evidence. The only testimony as to infringement is that of the visit of petitioner's officers to respondent's plant in 1933 when it saw respondent using a method involving preheating the cork.

There is an argument by petitioner that the claims of reissue 19,117 should be construed broadly enough to cover both methods of heating. It is thought unnecessary to discuss that question because the proceedings in the Patent Office, the prior art and petitioner's slide machine referred to at the end of the brief show that if there is any invention at all in reissue 19,117, the claims must be limited as correctly held by the Circuit Court of Appeals to the application of heat and pressure by a **heated cutting plunger** and **this** alone.

On pages 27 and 28 of petitioner's brief we find the following statement which is emphasized by Italics:

> "since the heated punch was not part of his original disclosure and was added to the application disclosure during the prosecution of the application merely as an example of a way 'to utilize at the time of assembly, both heat and pressure.' In re Dilg, 25 App. D. C. 9, 11."

This statement is clearly incorrect and not supported by the record. On the contrary the original application as filed (before the drawing was inserted) described a *heated plunger*. That there may be no doubt on the point, we quote from the original application as filed (p. 1246, Rec.):

"In carrying out the invention according to what is now considered the best practice the coating will be softened by heat after the crown is assembled. This may be accomplished in any suitable manner, as by a heated plunger or a plunger and heated table. The heat softens the coating and renders it adhesive and the pressure serves to unite the metal foil spot to the cork."

The argument of petitioner, however, overlooks the fact that claim 1 of the re-issue was only allowed over the art after repeated rejections by the Primary Examiner. The prior art showing no invention is referred to at pages *infra*, 47-53 of the brief. Petitioner in order to obtain any patent at all voluntarily cancelled the description and claims for the preheating step. It is elementary and held by numerous decisions of this Court, typified by the case of *I. T. S. Rubber Co.* v. *Essex*, 272 U. S. page 429 that when an applicant for a patent cancels matter in the Patent Office he cannot in a suit for infringement have a construction of a claim which would include the cancelled matter.

Petitioner cited several cases on pages 24/5 of its brief to the effect that a belief in the scope of its issued claims excuses it for not claiming the preheating method sooner. This Court has held that such belief on the part of a patentee is no excuse.

Wollensak v. *Sargeant*, 151 U. S. 221 and cases cited;
McClain v. *Ortmayer*, 141 U. S. 419.

The case of *Radio Condenser Co.* v. *Coe*, Court of Appeals, District of Columbia, 75 F. R. (2d) 523, is to the same effect.

The record clearly shows that, as found by the Circuit Court of Appeals, (p. 1835/6, Rec.) respondent always used a cold cutting plunger (p. 216/7 and ~~280~~, Rec.). 282

Briefly stated, the evidence for respondent shows that in the latter part of December, 1924 and between January and March, 1925 it made and sold upwards of 300,000 caps with center spots secured by gutta percha. They were made on

what is known as a Clark-Johnson assembling machine, which is a machine covered by patent No. 1,134,031 found at page 1508/14, and is for fastening the cork cushion disc into the metal shell. Benno Cohn, secretary and production manager of respondent company and Charles H. Rasmussen its superintendent testified respectively that they removed from the old Clark-Johnson machine the device which had formerly been used for cutting out a paper collett (placed between the metal shell and the cork disc) and substituted therefor a device for cutting out the spots and preheated the metal shells with the cork discs therein before the center spot was applied, pages 208/10; 279/81, Record. The reason that only some 300,000 caps were made was that the Inecto Co., a manufacturer of hair dyes, for whom these caps were manufactured by respondent, decided that the gutta percha might be deleterious to the substance it used in its hair dye and went back to the style of cap respondent had previously made for it and has been making for it since, viz., a metal center spot flanged into the cork (pp. 182/3, Rec.) made like those shown in the Nielson patent (No. 1,195,392, Figs. 13 and 15, p. 1648, Rec.) ~~infra~~.

The officers of the Inecto Co. corroborated Cohn and Rasmussen on this point. Original bills from respondent to the Inecto Co. running from March, 1925 were produced and identified by officers of that company, pages 179/82, Record, Exhibits CC to GG, page 926; JJ to LL, pages 929/35. The people who sold the gutta percha to respondent and the people who furnished the tinfoil and mounted the gutta percha on it for making caps on the dates mentioned, were called and identified invoices for both foil and gutta percha dated December, 1924 and January, February and March, 1925, pages 153/5; 187/90; 191/5. The bills are in evidence, (Exs. OO to ZZ, pp. 939/~~99~~ 959 Rec.). Cohn and Rasmussen both testified that they used a cold plunger for cutting the center spot and never, at that time or any time subsequently used a heated plunger (p. 216/17 and 282, Rec.).

The District Court found as a fact that such caps were made and sold. The Court also said, page 1781, Rec.:

"it does show that the use of gutta percha and metal for spotting strips was known to the art."

The Court of Appeals, however, in reversing the District Court, on the question of infringement, said in its opinion, page 1835, Record:

> "the defendant does not infringe, for the defendant uses a cold cutting punch which positions the spot on a cork disc previously heated sufficiently to cause the spot to adhere while the cap is carried to the next stage, where a hot plunger applies heat and pressure."

While the Court of Appeals did not say anything about that prior use by defendant, it clearly adopted it and adopted the testimony of respondent's witnesses to the effect that respondent always used a cold cutting punch and never used the heated plunger shown, described and claimed in the "heated plunger patent" (Reissue 19,117).

POINT V.

Both of the method patents are invalid over the prior art.

Respondent has contended in both the lower courts from the beginning of the suit that both of the method patents are invalid over the prior art.

Respondent again urges in this Court the invalidity over the art of both of these method patents.

This Court held in the case of *Stelos* v. *Hosiery Motor-Mend Corp. et al.*, 295 U. S. 237 that the respondent as a ground for sustaining a judgment in its favor is entitled to reassert a defense made in, but not accepted by, the Court of Appeals and that respondent need not make a cross application for a writ for this purpose.

In any event the history of the art is vitally necessary as it is elementary that the claims of a patent must be construed in the light of the art shown by the record. In the case at bar, petitioner's whole case hinges largely upon the construction to be placed upon the claims in the re-issue patent as well as upon Patent No. 1,967,195.

The crown cap is a metal shell having a disk therein of either composition or natural cork. The Record shows that the metal shell with the cork disk and secured to the metal shell by means of a heat fusible adhesive subjected to heat and pressure were old as far back as the Painter Patent of 1892 No. 468,226, page 4, lines 11-108-128 (p. 1502, Rec.).

The patent to Painter No. 792,284 (p. 1234, Rec.) June 13th, 1905, p. 1, lines 11-47-56 and the patent to Wheeler No. 887,883 (p. 1216, Rec.) dated May 19th, 1908, shows the same thing.

Another patent to Painter No. 887,838 (p. 1227, Rec.) dated May 19, 1908 (cited as showing the state of the art) states at page 1, lines 16, *et seq.*,

> **"then properly heating the cap, gasket and said medium and meantime subjecting the whole to appropriate pressure and while still under such pressure, cooling the completed closure."**

The McManus patent No. 1,339,066 (p. 530, Rec.) (one of the patents upon which suit was brought and held invalid by the Circuit Court of Appeals over the art) states (p. 2, lines ~~220 to 225~~) that the method of securing the cork lining to the metal shell with a fusible binding material and heat and pressure is old. In fact, the District Court so found (p. 1771/2, Rec.).

It would seem obvious and not to amount to invention when the prior art shows the securing of a cork disk to a metal shell by a fusible binding medium with heat and pressure to apply the same method to applying a center spot to a cork disk. This is particularly so when it is considered that the Record shows that center spots *per se* secured by

some sort of adhesive were old long prior to the filing of the application of either of the patents in suit.

The British patent to Demuth No. 16,075 (p. 1628/30, Rec.) effective date July 8th, 1914 shows a crown type cap having a cork cushion disk and a center spot of metallic foil or light, thin liquid resisting material *cemented* to the central portion of the cushion disk.

The use of a metal foil or strip from which the spots are cut, coated with a heat fusible adhesive is concededly old. One of the patents included in the six upon which the suit was originally brought is a patent to Warth No. 1,899,782, the claims of which are for strip material from which center spots are cut. The District Court found this patent invalid over the art and petitioner conceded its invalidity by failing to appeal from the decree holding it invalid.

Yet as pointed out on pages 10/11 *supra* of the brief, the use of such a strip is the primary concept of the method covered by patent 1,788,260 (the original of the reissue.)

The patent to Alberti No. 1,199,026 dated Sept. 19th, 1916 (p. 1022, Rec.) states at lines 35 to 43, page 2 referring to the adhesive material.

> "or it may be carried by a layer of fibrous material that is to be interposed between the two disks * * *, the entire closure being put, if necessary, under pressure and heated, whereby the cementing medium is coagulated, holding thus the metallic disk in place."

Referring again to the McManus Patent No. 1,339,066 (held invalid) that patent states (p. 2, ll. 20 to 35) that the center spot is secured to the cork disk by the use of a fusible binding medium interposed between the cap and the disk **"and set in a manner to unite the parts by the application of heat and pressure simultaneously or successively."** (lines 33-35)

and ll 73-84

Warth, the patentee of both the patents in controversy, himself admits that the use of heat and pressure for securing a center spot to the cork disk or cushion by means of a thermoplastic adhesive is old.

Warth filed an application for patent on Bottle Caps on August 21st, 1926. The Serial No. was 130,631 and it is found at page 1731, Record. That application states (p. 1737):

> "This paper disk is then secured to the cork disk by means of a backing 16 of some elastic and adhesive tissue, e.g., gutta percha **by means of a heated plunger or the like.** By so applying heat and pressure to the assembled cork and paper disks, the gutta percha or like backing is rendered adhesive and the paper spot is firmly cemented to the cork. **In this connection, it is noted that apparatus for cutting and assembling spot centers is known in the art."**

The claims in that application 130,631 were directed to a bottle cap having a center spot secured by gutta percha. The claims were rejected on the art by the Primary Examiner. His action was affirmed by the Board of Appeals and the application became abandoned.

The application for patent No. 1,967,195 (the preheating patent) became involved in interference with Johnson patent No. 1,852,578 (Interference No. 66,201) referred to on page 36 *et seq., supra,* and the Examiner of Interference in a decision in that interference stated (p. 663, Rec.):

> "Attention has been called to the patents to McManus #1,402,780 and Alberti 1,401,300, showing machines for this purpose. In these machines the caps are passed intermittently in single file beneath a reciprocating punch, which cuts the metal foil disk from a strip and deposits it upon the cork pad. **The caps then pass to an immediately adjacent heated plunger which applies sufficient heat and pressure to complete the union.** It was agreed by both parties at the hearing that machines of this character were used commercially prior to 1927 and that they operated at high speed."

It may be noted here that, stripped of all technical terminology, the essence of the claims of both the patents in controversy are for a *method* only of cutting a center spot from

a strip of thermoplasticly coated material (concededly old) and sticking or adhering it to the cork disk by means of heat and pressure also concededly old and by apparatus also concededly old.

The re-issue or heated plunger patent describes and claims a method whereby the heat is supplied by the cutting plunger. The alleged divisional or preheating method patent obtains the heat necessary for initially adhering the spot by heating the cork first so as to obtain the necessary heat for sofening the gutta percha sufficiently to cause it to adhere and later applying heat and pressure.

In addition to the art we have referred to, petitioner itself produced a witness by the name of Goebel, its Plant Engineer and Superintendent, who produced drawings of and described a machine for putting center spots coated with gutta percha on cork disks in crown caps as far back as 1915 or 1916. This machine was termed the "slide machine". A drawing of it was produced (Ex. 43) (p. 612, Rec.) and put in evidence by petitioner (p. 370, Rec.). That machine concededly operated slowly, but, nevertheless, it showed two strips of a material, one of tin foil and the other of gutta percha, from which the center spots were cut out and applied by heat and pressure to the cork disk. In speaking of this machine, the Court of Appeals said (p. 1836, Rec.):

> "To read the claims of the re-issue patent to mean a cold punch to cut the spot and a hot plunger applied later to fasten it to the cork disk would make them invalid under the old slide machine * * *."

Petitioner in its brief criticizes this decision of the Court of Appeals and seeks to differentiate the old slide machine on the ground that it does not show the application of heat and pressure and has made an elaborate statement on page 41 of the appendix to its brief attempting to differentiate the machine. However, we think a complete answer to this description is found in petitioner's own Exhibit 44 (p. 613,

Rec.) from the head of petitioner's engineering department which states in part:

> "A crown has now come into position under the Plunger and Heater 'H' which has moved into position relative to applying the spot to the crown. This is accomplished by the action of the pump 'B', which on its return stroke blows the spot from its position in the Heater on to the Crown *which is then pressed on to the cork in the crown by the Heater Plunger.* This completes the cycle of operations necessary for applying the Tin Foil Spot to the assembled #1 Crown."

The District Court in discussing that slide machine said (p. 1790, Rec.):

> "The pressure of this heated punch caused the gutta percha to stick to the cork and also to the foil spot."

It is submitted that in view of the art and petitioner's slide machine there can be no invention in the claims of either of the two method patents involved in this appeal under the decisions of this Court in the following cases:

> *Altoona Theatres* v. *Tri-Ergon Corp.*, 294 U. S. 477;
> *Powers-Kennedy Contracting Corp.* v. *Concrete Mixing & Conveying Co.*, 282 U. S. 175;
> *Thomson Spot Welder Co.* v. *Ford Motor Co.*, 265 U. S. 445.

The Court's attention is directed to the fact that all the claims in the two patents in controversy are for a mere function of a machine and call for the method of applying heat and pressure to a center spot cut from a strip of adhesively coated material to cause the spot to adhere to the cork. No particular amount of heat and no particular amount of pressure is specified. It would seem as though the Court could take judicial notice of the well known fact that when it is desired to stick one material to another by means of gutta percha, the gutta percha must be softened by heat and pressed on to some material.

The patent to Farrell No. 1,358,834 (p. 1135, Rec.) issued November 16th, 1920 (p. 1, ll. 74-88) shows the use of gutta percha as an adhesive for use on strips of paper or tapes, etc. and the application of same by heat and pressure.

The whole proposition is really an apparatus or machinery proposition. The speed and rate of production of caps is governed by the machinery employed. The District Court found (p. 1791, Rec.):

> "The defendant's Cohn and Johnson machines are different from plaintiff's, but that machinery operates in accordance with the Warth method, and that defendant has not been able to equal plaintiff's high rate of production is no defense."

If the claims in the patents in controversy are sustained, then it will be impossible for anyone who constructs a greatly improved machine and gets an even higher rate of production than that obtained by petitioner's machines to use such improved apparatus.

It would seem that the following authorities holding that there can be no invention in the function of a machine are peculiarly applicable here.

Westinghouse v. *Boyden Power Brake Co.*, 170 U. S. 537 at pages 555-8;

DeForest Radio Co. v. *General Electric Co.*, 283 U. S. 664, pages 682-4;

E. Van Norden Co. v. *Cheney*, 75 Fed. 298 (C. C. A. 1) at page 302;

Directoplate v. *Donaldson Lith. Co.*, 51 F. R. (2d) 199.

IN CONCLUSION.

Petitioner's argument as to the validity of Patent No. 1,967,195, is based upon the rule announced in *Chapman* vs. *Wintroath*, as construed in *Webster* vs. *Splitdorf*, that a divisional application may be filed for the purpose of getting

into interference with a patent issued to a third party, at any time within two years of the issue of said adverse patent; and upon the contention that the claims contained in Patent No. 1,788,260, as issued, now reissue Patent No. 19,117, were of a scope to cover the matter claimed in the alleged division, No. 1,967,195, and if not that at least Warth believed they were, and was thus absolved from any imputation of laches.

As to Re-issue Patent 19,117, briefly, petitioner bases its claim of infringement upon the same contention, that it uses as an excuse for laches, namely that the claims cover the preheating step.

The complete answer to the argument is that in the *Chapman* and *Webster* cases and in all of the numerous decisions based thereon the parent patent had not issued, and the time within which to file a divisional application was computed from the date of the adverse patent and the subject of the inventions had not been cancelled. In the instant case the applications relied upon for continuity of disclosure were not true divisional applications as we have shown, *supra,* but that fact aside, the issuance of the parent patent makes applicable the strict rules in regard to re-issues rather than the more liberal rule in regard to divisional applications. Warth having waited more than two years to file his alleged second divisional application is confronted with the fact the parent application is a "printed publication" within the meaning of the statute. *Ludlum Steel Co.* vs. *Terry,* 37 Fed. (2) 153 at 165; *Milburn Co.* vs. *Davis,* 270 U. S. 390 at 402. Quite apart from authority it is obvious that the file wrapper of an allowed application being open to the public is notice of its contents.

The decision of the Circuit Court of Appeals should be affirmed on account of the foregoing and also for the following reasons:

1. Warth's conduct in voluntarily cancelling the preheating disclosure and claims broad enough to cover same from

his parent application and allowing the patent to issue without any reference to preheating before filing claims for the alleged invention in the later application amounts to abandonment in fact as found by the Court of Appeals.

2. His failure to take action to protect his alleged invention for more than four years after the purchase by Petitioner of machines from Johnson and more than two years after Respondent wrote to Petitioner concerning charges it was violating Petitioner's patent rights.

3. Because the two patents before the Court are completely void in view of the prior art.

4. As to non-infringement, the court below should be affirmed upon the grounds so concisely and cogently stated in its own opinion (Rec., pp. 1834-5).

Respectfully submitted,

WILLIAM E. WARLAND,
FRANCIS H. WARLAND,
NATHANIEL L. LEEK,
Counsel for Defendant-Respondent.

APPENDIX.

Patent Office Rules:

35. The specification must set forth the precise invention for which a patent is solicited, and explain the principle thereof, and the best mode in which the applicant has contemplated applying that principle, in such manner as to distinguish it from other inventions.

36. In case of a mere improvement, the specification must particularly point out the parts to which the improvement relates, and must by explicit language distinguish between what is old and what is claimed as new; and the description and the drawings, as well as the claims, should be confined to the specific improvement and such parts as necessarily cooperate with it.

37. The specification must conclude with a specific and distinct claim or claims of the part, improvement, or combination which the applicant regards as his invention or discovery.

41. Two or more independent inventions can not be claimed in one application; but where several distinct inventions are dependent upon each other and mutually contribute to produce a single result they may be claimed in one application; *Provided,* That more than one species of an invention, not to exceed three, may be claimed in one application if that application also includes an allowable claim generic to all the claimed species. In the first action on an application containing a generic claim or claims and claims to more than one species thereunder the examiner, if he is of the opinion after a complete search that no generic claim presented is allowable, shall require the applicant in his response to that action to elect that species of his invention to which his claims shall be restricted if no generic claim is finally held allowable.

43. When an applicant files two or more applications relating to the same subject matter of invention, all showing but only one claiming the same thing, the applications not claiming it must contain references to the application claiming it.

93. An interference is a proceeding instituted for the purpose of determining the question of priority of invention between two or more parties claiming substantially the same patentable invention and may be instituted as soon as it is determined that common patentable subject matter is claimed in a plurality of applications or in an application and a patent. In order to ascertain whether any question of priority arises the Commissioner may call upon any junior applicant to state in writing under oath the date and the character of the earliest fact or act, susceptible of proof, which will be relied upon to establish conception of the invention under consideration. The sworn statement filed in compliance with this rule will be retained by the Patent Office separate from the application file and if an interference is declared will be opened simultaneously with the preliminary statement of the party filing the same. In case the junior applicant makes no reply within the time specified, not less than twenty days, the Commissioner will proceed upon the assumption that the said date is the date of the oath attached to the application. The fact that one of the parties has already obtained a patent will not prevent an interference, for, although the Commissioner has no power to cancel a patent, he may grant another patent for the same invention to a person who proves to be the prior inventor.

94. Interferences will be declared between applications by different parties for patent or for reissue when such applications contain claims for substantially the same invention which are allowable in the application of each party, and interferences will also be declared between applications for patent, or for re-issue, and unexpired original or re-issued patents, of different parties, when such applications and patents contain claims for substantially the same invention which are allowable in all of the applications involved: *Pro-*

vided, That where the filing date of any applicant is subsequent to the filing date of any patentee, the applicant shall file an affidavit that he made the invention in controversy before the filing date of the patentee.

Where claims are copied from a patent and the examiner is of the opinion that the applicant can make only some of the claims so copied, he shall notify the applicant to that effect, state why he is of the opinion he cannot make the other claims and state further that the interference will be promptly declared and that the applicant may proceed under rule 109, if he further desires to contest his right to make the claims not included in the declaration of the interference.

Where an applicant presents a claim copied or substantially copied from a patent, he must identify the patent, give the number of the patented claim, and specifically apply the terms of the copied claim to his own disclosure.

An amendment containing a claim copied from a patent granted more than two years prior to the filing of such amendment shall not be entered unless it be accompanied by a statement specifically pointing out the claim or claims upon which the applicant relies to show that he was claiming the subject matter of the copied claim or claims within two years from the date of the patent.

Parties owning applications or patents which contain conflicting claims will be required to show cause why these claims shall not be eliminated from all but one of the applications or patents of common ownership.

U. S. Revised Statutes:

Sec. 4899. (U. S. C., title 35; sec. 48.) Every person who purchases of the inventor or discoverer, or, with his knowledge and consent, constructs any newly invented or discovered machine, or other patentable article, prior to the application by the inventor or discoverer for a patent, or who sells or uses one so constructed, shall have the right to use, and vend to others to be used, the specific thing so made or purchased, without liability therefor.

Sec. 4916. (U. S. C., title 35, sec. 64.) Whenever any patent is wholly or partly inoperative or invalid, by reason of a defective or insufficient specification, or by reason of the patentee claiming as his own invention or discovery more than he had a right to claim as new, if the error has arisen by inadvertence, accident, or mistake, and without any fraudulent or deceptive intention, the commissioner shall, on the surrender of such patent and the payment of the duty required by law, cause a patent for the same invention, and in accordance with the corrected specification, to be reissued to the patentee or to his assigns or legal representatives, for the unexpired part of the term of the original patent. Such surrender shall take effect upon the issue of the re-issued patent, but in so far as the claims of the original and reissued patents are identical, such surrender shall not affect any action then pending nor abate any cause of action then existing, and the reissued patent to the extent that its claims are identical with the original patent shall constitute a continuation thereof and have effect continuously from the date of the original patent. The commissioner may, in his discretion, cause several patents to be issued for distinct and separate parts of the thing patented, upon demand of the applicant, and upon payment of the required fee for a reissue for each of such reissued letters patent. The specifications and claims in every such case shall be subject to revision and restriction in the same manner as original applications are. Every patent so reissued, together with the corrected specifications, shall have the same effect and operation in law, on the trial of all actions for causes thereafter arising, as if the same had been originally filed in such corrected form; but no new matter shall be introduced into the specification, nor in the case of a machine patent shall the model or drawings be amended, except each by the other; but when there is neither model nor drawing, amendments may be made upon proof satisfactory to the commissioner that such new matter or amendment was a part of the original invention, and was omitted from the specification by inadvertence, accident, or mistake, as aforesaid.

CROWN CORK & SEAL COMPANY, INC., Plaintiff-Petitioner, v. FERDINAND GUTMANN & CO., Defendant-Respondent.	No. 72

SUPPLEMENTAL BRIEF FOR DEFENDANT-RESPONDENT.

Petitioner has filed two reply briefs, one directed to the case generally and one solely to the question of validity over the prior art. Petitioner has raised some new points therein not previously referred to in the case and respondent feels obliged to reply thereto briefly.

Abandonment.

Petitioner, on page 3 of its reply brief raises the point that the defense of abandonment was not pleaded in accordance with the statutes and therefore respondent cannot argue the point at this time.

In its numerous briefs before the District Court, the Circuit Court of Appeals, and in this Court in its briefs in support of the petition for the writ, and in its main brief on this argument Petitioner never raised this point, although the question of abandonment was distinctly raised and passed on by the District Court which said in its opinion in discussing the two patents in controversy (p. 1800, Rec.):

> "The subject matter was not abandoned, *as suggested by defendant,* but was specifically reserved by continuous inclusion in the divisional application and later in the second division."

The cases cited by petitioner* on page 3 of its brief to the effect that the rules of pleading require that the defense of abandonment must be pleaded before proof can be offered in support of it, were all concerned with cases in which the *invention* had been abandoned either before filing application for patent or by some failure to comply with the rules of the Patent Office during the course of the application, and none were concerned with a situation where an applicant either failed to assert any claim to subject matter of an application or deliberately cancelled such subject matter in order to obtain a patent.

The following language of the Court of Appeals (p. 1838, R.) in reference to the two patents involved in the case, at bar, while not specifically mentioning the word "abandonment" indicates that it considered Warth had in fact abandoned his preheating claims.

> "but, in the case at bar, for a period of more than two years Warth apparently did not wish to claim the preheating method, having deliberately cancelled the preheating specification from his original application and shaped his claims so as to exclude it and his patent having been granted January 6, 1931."

We think it is immaterial whether the act of Warth is termed an actual or constructive abandonment, or *laches* which amount to abandonment. We believe that the theory upon which this court decided the case of *Webster* v. *Splitdorf* was that the inventor in that case had been guilty of

---

* *Mast Foos & Co.* v. *Dempster,* (C. C. A. 8th) 82 F. 327; *Western Electric Co.* v. *Sperry Electric Co.,* (C. C. A. 7th) 58 Fed. 186, 192; *Warren Featherbone Co.* v. *Warner Bros. Co.,* (C. C. Conn.) 92 Fed. 990, 991; *U. S. Electric* v. *Consolidated,* (C. C. N. Y.) 33 Fed. 869, 871; *Abrahams* v. *Universal Wire Co.,* 10 F. (2d) 838, 842 (D. C. E. D. N. Y.).

such *laches* as to amount to abandonment. The Court of Appeals in this case, as we pointed out on page 9 of our main brief, said in the case of *Western Electric* v. *General Talking Pictures Co.* in speaking of the case at bar:

> "The patentee (Warth) had really abandoned the invention, and we said, 'might never have considered the subject worth claiming as an invention.'"

Abandonment is a question of intent and intent can only be proven by a man's acts. This court said in the case of *Planing-Machine Co.* v. *Keith*, 101 U. S. 479 at page 484:

> "It has sometimes been said that an invention cannot be held to have been abandoned, unless it was the intention of the inventor to abandon it. But this cannot be understood as meaning that such an intention must be expressed in words. In Kendall et al. v. Winsor (21 How. 322), this Court said, 'it is the unquestionable right of every inventor to confer gratuitously the benefits of his ingenuity upon the public, and this he may do either by express declaration or by conduct equally significant with language; such, for instance, as an acquiescence with full knowledge in the use of his invention by others; or he may forfeit his rights as an inventor by a wilful or negligent postponement of his claims. * * * but it is obvious there may be an abandonment as well after such an application has been made and rejected, or withdrawn, as before, and evidenced in the same manner.'"

Following that decision this court said in *Rifle and Cartridge Co.* v. *Whitney Arms Co.*, 118 U. S. 22:

> "The decision of the Commissioner in favor of the applicant, upon the question whether the invention has been abandoned, is not conclusive, but may be contested and reviewed in a suit brought for the infringement of the patent."

The application for patent 1,788,260 (parent of the reissue) filed Jan. 7th, 1927 had no disclosure to entitle Warth to have that application placed in interference with Johnson.

In answer to Petitioner's contention, page 20 its Reply Brief, attention is called to the following.

On page 5 of its main brief petitioner states:

> "The Warth generic method, as it would be carried out with this illustrated 'suitable mechanism,' is shown by the drawing opposite this page."

An inspection of that drawing shows:

> "Fourth step—Applying heat and pressure after placing spot."

Below that statement is shown a plunger heated by gas.

That "Fourth step" and the heated plunger for accomplishing it never appeared in the application for patent 1,788,260 (the parent of the reissue). It was not described in the specification of that original application. That original application as filed said nothing about "A fourth step" or "Applying heat and pressure after placing spot."

Attention is called to the drawing, which we have reproduced on the opposite page, of reissue 19,117 which is the same drawing that appears in the parent patent 1,788,260. There is nothing in the application for the original 1,788,260 referring to "Applying heat and pressure *after* placing spot."

The first time that the "Fourth step" in the drawing of petitioner's brief opposite page 5 ever appeared in the Patent Office was when Warth filed the alleged divisional application on April 4th, 1933, which resulted in Patent No. 1,967,195. Fig. 6 appeared **for the first time** in that application as filed. Patent 1,967,195, in describing that figure 6, says (p. 4, ll. 16 *et seq.*):

> "As hereinbefore stated, after the spot is positioned on the sealing pad heat and pressure may be applied, as by a plunger or a plunger and heated table. In Fig. 6 there is shown for this purpose a carrier i and a spring pressed plunger j. The plunger j is heated by gas jets, and thus the plunger serves as means for applying a continuing heat and pressure after the punching opera-

PAGE

tion to ensure complete fusion of the adhesive and a close adhesion of every portion of the disk 15 to the disk 18."

This matter was inserted by amendment filed June 21st, 1934 as a substitute for the following matter in the disclosure as filed:

"It is preferable after the disk 15 has been bonded to the cork disk 18, to thereafter subject them to continuing heat and pressure for a sufficient interval to ensure the complete fusion of the gutta percha and a close adhesion of every portion of the disk 15 to the disk 18. For this purpose, I have shown (Figure 6) a carrier i and a spring pressed plunger j. In the drawings, I have shown the punch 20 and plunger j as being heated by gas jets, but this is immaterial to the invention and other heating means may be employed." (p. 1438, Rec.)

No such disclosure appears in the application for the parent of the reissue, or in any of the intervening applications, viz. the strip material application, nor in either of the cap and method patents referred to in our main brief, so far as the record shows.

Obviously this additional figure and the statement we have quoted was put in for the sole purpose of justifying Warth in getting into interference with the Johnson patent. Unless he had in his application filed April 4, 1933 a means and description of applying heat and pressure after the spot was cut without the limitation of the temperature

"sufficient to fuse or soften the adhesive coating and make it tacky so that, *at the time the disk is assembled with the cap,* the heat and pressure will cause the disk to be adhesively united to the surface of the cushion material * * *." (Rec., p. 557, ll. 7 to 15.)

he would have had no disclosure for the expression in Claim 2, viz:

"and then placing the linings in the caps under heat and pressure to effect an intimate adhesion between the linings and pads" (p. 557, ll, 123/6, Rec.).

and the expression in Claim 3:

> "then placing the linings in the caps under heat and pressure to effect an intimate adhesion between the linings and pads etc." (p. 557, ll. 138/42, Rec.).

As to claim 1 of patent 1,967,195 (claim 28 of the Johnson patent 1,852,578) the original application for patent 1,788,260 did not disclose in the specification or drawings a *cold cutting punch,* shown in the drawing opposite page 6, Petitioner's Brief.

This clearly shows that the alleged division 1,967,195 is not in any sense a proper division of either 159,743, the application for the parent of the reissue, nor is it a proper division of the strip material patent 494,201 because it has matter which was not shown or described in either, and it was for a step not set forth in either the patent or the application.

This new and additional step called for in application for patent 1,967,195, the preheating patent, and illustrated in said sketch opposite pages 5/6 of Petitioner's main Brief, is supplemental to the attachment of the center spot to the disc by the simultaneous application of heat and pressure immediately following the cutting of the disc from the strip material and by the same agency. In this connection the Court's attention is also directed to the drawing opposite page 6 in Petitioner's main Brief in which it is noted that the number and relation of parts is the same as in the other sketch opposite page 5 with the following exceptions:

A burner is shown for heating the discs as they approach the dies for cutting the spot from the strip material and the plunger of the cutting die is shown as being without heat of any kind which also is foreign to any disclosure made by Warth either in his application for patent No. 1,788,260 (Reissue 19,117) or in any other application of record. The court is most earnestly urged to compare the drawings of the reissue patent 19,117 appearing opposite this page and

the two drawings opposite pages 5 and 6 respectively of Petitioner's main Brief.

The practice followed by Warth in this case is on all fours with that referred to by this court in *Coan* vs. *Wilson*, 113 U. S. 268, cited at page 41 of our main brief in that after Warth had knowledge of the Johnson patent, he deliberately filed his alleged divisional application including matter which would enable him to insert claims covering the Johnson invention notwithstanding that this matter never appeared in any of his prior applications. **In connection with petitioner's insistence that no interference was declared between the Johnson patent and the Warth application on appeal, it is obvious that Warth was never entitled to make the claims of the Johnson patent until he filed the application for the preheating patent 1,967,195, in April, 1933 showing the additional matter supporting such claims.**

It is apparent that the matter on the drawing opposite page 5/6 of Petitioner's main brief have no support in either the application for the reissue or the preheating application of April 4th, 1933.

Consequently when the Examiner made his interference search before the issue of the Johnson patent there were not only **no claims** conflicting with Johnson's claims (as pointed out on p. 23/4 of our main brief) but there was **no disclosure** in any of Warth's various applications which would support such claims.

Cases Cited By Petitioner.

A careful reading of the cases cited by petitioner (pp. 10-23) on the questions of divisional applications, continuing applications, publication, reissues and other points relevant to the prosecution of an application through the Patent Office, having in mind the difference between the facts disclosed in each and the facts in the case at bar, shows that they in no way affect the position taken by respondent upon those points in its briefs previously filed herein.

Furthermore, in the opinion of counsel, it has been shown so conclusively that application Ser. No. 494,201, and the application for Patent No. 1,967,195, were not, and could not be, true divisions of Patent No. 1,788,260 that it is unnecessary to further consider the cases on the points mentioned.

Warth-Johnson Interference 66201.

Petitioner (Reply Br., p. 34) cites *Chillis* vs. *Weisberg*, 1928 C. D. 24 and argues that respondent did not attempt to offer evidence showing invention by Johnson prior to the filing date of the Warth application for Patent No. 1,788,260. The attention of the Court has been heretofore called to the fact that there is no disclosure in this application even as originally filed corresponding with the disclosure of the Johnson application.

Johnson assigned his patent to petitioner in December, 1933 and received at the time of said transfer from petitioner a license to manufacture the apparatus of that patent. This would seem to be a complete refutation of the claim that this assignment was ever put in escrow. The original assignment contains no reference to any escrow agreement, but was an absolute transfer.

There is nothing of record in the Patent Office to show that in determining the Warth-Johnson interference the Examiner of Interferences had any knowledge of this assignment and up to the time of the trial the assignment was never placed on record in the Patent Office (p. 440, Rec.).

Respondent is licensed to use the machines it bought from Johnson.

It is stated that petitioner is not clear as to the license right of respondent to use the Johnson machines (p. 35, Petr's. Reply Br.). Respondent therefore restates the conditions resulting in this license. Johnson invented a certain machine for applying the center spots to crown caps and

later took out a patent upon that machine which patent contained 27 apparatus claims and the 3 method claims in suit. Both before and after the filing of the Johnson patent and before and after the granting of said patent respondent purchased machines from Johnson, the inventor and legal owner of the apparatus and of the patent, and under the statute and under elementary law as to patents thereby became vested with the right to use these machines. Petitioner does not dispute that Johnson was the inventor and the lawful owner of the patent for such *apparatus*. Petitioner later purchased from Johnson his patent covering such apparatus. It would seem obvious that Johnson could not bring any proceeding against respondent for the use of those machines. It would seem equally obvious that petitioner having acquired title to the Johnson patent by purchase could not proceed against respondent for the use of Johnson's machines since it could get no greater rights than Johnson had. After purchasing the patent from Johnson petitioner granted Johnson an *unrestricted* license to manufacture the apparatus of that patent. Today Johnson alone or joined with petitioner could not bring an action against respondent for the use of such apparatus. The whole difficulty arises because of the interference proceeding referred to at pages 36/37, main brief, by which Warth obtained the patent upon the claims covering the functioning of the Johnson apparatus, although actually Warth was not the inventor of that apparatus, but Johnson was. And when everything is said and done, the three method claims of Johnson which became the three method claims of the Warth patent 1,967,195 call for nothing except the functioning of the Johnson apparatus.

Petitioner on page 36 of its reply brief, refers to the case of *Hartford Empire Co.* vs. *Nivison-Weiskopf Co.*, 58 Fed. (2) 701 and says:

"The facts were the same as in the case at bar."

An inspection of the cited case shows it has not the slightest application and the facts are not even remotely analogous

to the facts in the case at bar. In the case at bar, respondent purchased the machines from *Johnson*. That is not denied either in the main or reply brief of petitioner. In the case at bar, petitioner, after the institution of the alleged interference with Johnson, purchased the Johnson patent with the 27 apparatus claims and the Johnson patent had the three method claims in controversy.

The Court said in the *Hartford Empire Co.* case, at pages 705/6:

> "It is, however, equally true that the purchase of the Miller applications by the plaintiff did not give the defendant, as licensee of Miller, any license to *other patents or applications outstanding*, and the suit here in question is upon a patent in *which Miller had no property interest* and which, rightly or wrongly, was held in the Patent Office to take precedence over the Miller applications."

The difference between the *Hartford* case and the case at bar is that in the case at bar respondent is licensed under the statute and the decisions of this Court mentioned on page 36 of our main brief, to use the apparatus described and claimed in the Johnson application and patent which petitioner purchased, with full knowledge of defendant's use of the same, and the claims of that patent purchased by petitioner are the ones in controversy. In the cited case an attempt was made to establish a license from Miller to the use of a feeder in which Miller had no legal rights. In the present case Johnson was the legal owner of a patent covering the apparatus used by respondent and the plaintiff purchased that patent from Johnson.

Petitioner's Discussion of the Fact Testimony.

Petitioner on pages 28 *et seq.* of its reply brief discusses the testimony of Cohn in reference to Exhibit Q. We think a fair reading of that testimony shows that what Cohn was saying was that the machine in which he afterwards com-

bined the spot and cork in one operation was the same kind as Exhibit Q. Petitioner refers to Cohn's answers to petitioner's interrogatories. It overlooks, however, the fact that the answers to interrogatories by respondent on page 44 of the record show that respondent had always used the preheating method shown by the Johnson patent.

In addition to that we refer to the evidence found on page 209, Qs. 44/5; page 254, XQs. 423/9; page 281. Particular attention is called to the answer to XQs. 486/7, pages 260/61 Record.

In connection with the purchase of the five machines by petitioner from Johnson in 1929, petitioner on page 32 of its reply brief again intimates that petitioner gave instructions to Johnson to build these machines. The evidence is quite to the contrary. There is not a word from any of the witnesses for petitioner to that effect. Petitioner's witness Goebel said, (p. 413, Rec.) in answer to XQ369:

> "A: We *bought* a couple of spotting machines from Johnson to be sent to our Toronto plant and we took them to our Highlandtown plant to ascertain that they would operate and run. * * *"

He said in answer to XQ373 that he did not know there were five. He only knew of two. Goebel was the building engineer on all production machinery and acquisition and maintenance of production machines (p. 366 Rec.).

Furthermore, on page 900 Record, there is a letter from Johnson to petitioner stating that petitioner would have to pay the freight. That is entirely inconsistent with petitioner's argument that these machines were built on special order by Johnson for petitioner.

Prior Art.

The petitioner has filed a lengthy supplemental brief on the question of the art relating to center spot crowns.

In reply to that brief, it is merely desired to state that center spot crowns of the type referred to in the two patents before the Court were admittedly manufactured and sold by petitioner, or its immediate predecessor, continuously from 1917 (pp. 1589/91 Rec.) to the time of the suit, and that these caps had a cushion disc and a metal foil spot accurately centered in relation to the cushion disc and bonded thereto by means of gutta-percha tissue.

It is conceded that gutta-percha tissue is a thermo-plastic or heat fusible material and the Court found (p. 1790 Rec.) that heat and pressure were used in the operation of the slide machine to fuse the gutta-percha and cause the center spot to adhere to the cushion disc by pressure from a heated plunger, placing the spot upon the cushion disk. This same procedure was also disclosed in the "apparatus for cutting and assembling spot centers" referred to in Warth's abandoned application (p. 1737, Rec.).

The patents of Warth directed to such a center spot crown were held to be invalid by both the District Court and the Circuit Court of Appeals, 2nd Circuit (pp. 1831/2 Rec.).

Strip material coated with gutta-percha as an adhesive, made the subject matter of another patent in suit, was used by defendant in the early part of 1925 (p. 1781 Rec.), and the Court held that Warth was not the inventor of such strip material. In view of the above, it is submitted that a detailed discussion of prior art patents further than that set forth in our main brief (pp. 47/53) is not enlightening and therefore respondent refrains from any further discussion thereof.

At this point, however, we repeat that it is obvious that Warth's alleged invention, if any, was for a mere functioning of a machine, and was not a proper method. As shown above the use of heat and pressure *per se*, in applying spots was old. The "process could be performed by hand or by different mechanisms." *Michigan Carton Co.* vs. *Sutherland Paper Co.*, 29 F. (2) 179, quoted at page 19

Petitioner's Supplemental Brief. The high rate of production and great commercial success claimed by petitioner were due to the improved *mechanism* used in practicing the old and well known method. In other words the machine was new, but the article and method were old.

IN CONCLUSION.

It is submitted that the decree of the Circuit Court of Appeals as to both patents should be affirmed.

Respectfully,

WILLIAM E. WARLAND,
FRANCIS H. WARLAND,
NATHANIEL L. LEEK,
Counsel for Defendant-Respondent.

IN THE

SUPREME COURT OF THE UNITED STATES

OCTOBER TERM 1937.

CROWN CORK & SEAL CO., INC., Plaintiff-Petitioner, vs. FERDINAND GUTMANN & COMPANY, Defendant-Respondent.	No. 72.

Now comes the respondent by its counsel and moves that the judgment of this Court provide that the costs in this Court abide the decision of the U. S. Circuit Court of Appeals for the Second Circuit of the issues in the case not heretofore passed upon, in accordance with the opinion of this Court, for the following reasons:

That the decision of this Court dated May 2nd, 1938 was limited to one of the specific questions presented by the Writ of Certiorari and the petition therefor, and the decision states at the end thereof:

> "As our decision is limited to the first question presented, the judgment of the Circuit Court of Appeals will be reversed and the case will be remanded to that Court for decision of the other issues in the case in accordance with this opinion."

The suit is one to restrain the alleged infringement of six patents. In the Courts below four of these patents were held invalid and the plaintiff-petitioner has acquiesced in said holding. In regard to one patent, Reissue 19,117, the Circuit Court of Appeals held the defendant did not infringe.

That Court held the remaining patent, Warth divisional No. 1,967,195 invalid for delay on the part of the patentee

in filing and prosecuting the same. A writ of Certiorari was granted by this Court to review the decision of the Circuit Court of Appeals.

The sole question passed upon by this Court concerned the divisional patent 1,967,195:

> 1. "Does this Court's decision in Webster Co. v. Splitdorf Co. (264 U. S. 463) mean that, even in the absence of intervening adverse rights, an excuse must be shown for a lapse of more than two years in presenting claims in a divisional application regularly filed and prosecuted in accordance with patent office rules"?

Opinion of this court herein dated May 2, 1938.

When the case was argued in the Circuit Court of Appeals for the Second Circuit there were presented to that Court in addition to the question of the delay in filing the divisional application, the question of validity of that patent over the prior art as well as of the other patents, intervening rights, the prior use by both plaintiff and defendant of the method set forth in the two patents which were before this Court; the question of whether respondent was entitled to a license under the Johnson patent, and the validity of the interference proceeding No. 66,201.

In regard to the divisional application, the Circuit Court of Appeals passed only on the question of the delay of the patentee Warth in filing and made no finding upon, and there was no reference in its opinion to the other questions above stated. In view of the direction of this Court contained in the language previously quoted, it now becomes necessary for the Circuit Court of Appeals to pass upon the questions presented by the defenses hereinbefore referred to and it may well be that the defendant in the action may ultimately prevail although unsuccessful upon the Certiorari to this Court. If such should be the case, it would seem inequitable that defendant-respondent should have to pay the costs in this Court, irrespective of the ultimate outcome of the

litigation, merely because said plaintiff-petitioner had been successful in regard to what would then have become an abstract question of law.

The position of the parties is similar to a case in which an unsuccessful party takes an appeal and a new trial is ordered. In such cases the ultimately prevailing party is usually entitled to recover all costs. Such is the rule in New York State where this litigation arose and we understand that in this regard it is the practice of the Federal Courts to follow that of the State Courts.

Ex parte Peterson, 253, U. S. 300 at 317.

In New York State Appellate Courts frequently direct that "costs shall abide the event".

11 Carmody's New York Practice, pages 388-89 and New York cases therein cited.

On the general proposition that only a completely successful party in patent litigation may recover costs, see *Sessions* v. *Romadka,* 145 U. S. 29 at 41; *O'Reilly* v. *Morse,* 15 How. 62 at 120 (dealing with U. S. R. S. Sects. 4920 and 4922), and *General Motors Corp.* v. *Leer Auto Supply Co.,* 60 F. (2d) 902; *Suddard* v. *American Motor Co.,* 163 F. 852.

The *opinion* of this court in the case at Bar is silent upon the question of costs, but we are informed by the Clerk that in the absence of a provision to the contrary, costs will be taxed in favor of the plaintiff-petitioner who obtained a "reversal". If it were not for the foregoing, we should assume that pursuant to sub-division 3 of Rule 32 of this Court, the court below would have power to make an award of the costs in this court. We respectfully submit that under the circumstances of this case the defendant-respondent should be awarded costs if ultimately successful and in order to pre-

vent any difficulty arising in regard thereto, ask that the mandate be amended to provide that the costs in this court abide the event of the litigation.

Dated New York, May 16, 1938.

Respectfully submitted,

WILLIAM E. WARLAND,
FRANCIS H. WARLAND,
NATHANIEL L. LEEK.

Counsel for Defendant-Respondent.

OCTOBER TERM, 1937.

CROWN CORK & SEAL CO., INC., Plaintiff-Petitioner, vs. FERDINAND GUTMANN & COMPANY, Defendant-Respondent.	No. 72.

REPLY MEMORANDUM FOR DEFENDANT-RESPONDENT ON MOTION TO AMEND JUDGMENT.

It is not necessary to discuss the authorities cited by petitioner other than to say that a careful examination of those cases shows that no one of them presents a question exactly like that presented by the record in this case.

Rule 32 of this court provides (Sub-Division 3):

> "In cases of reversal of any judgment or decree by this court, costs shall be allowed to the appellant or petitioner, *unless otherwise ordered by the court.*"

We would not file this memorandum were it not for the statements on pages 4 and 5 of petitioner-appellant's brief and the affidavit and letter annexed thereto which state that the large size of the record is due to the fact that counsel for defendant-respondent refused to agree to have less than the entire record reproduced.

It is quite true, as stated in the affidavit of Mr. Pawling that Mr. Warland desired to have the entire transcript of record reproduced. The affidavit, however, does not state that prior to the refusal, Mr. Warland had several telephone conversations not only with Mr. Pawling, but also with Mr. Darby in Washington looking toward a possible reduction

of the record. It was agreed after those conversations that the testimony of the various witnesses for both sides and many of the exhibits relevant to the two patents before this Court were so inextricably commingled with the other four patents that were not involved in the questions presented by the application for the writ, that it would be impossible to make an intelligible record before the case was reached for argument. The writ of certiorari was granted on Oct. 11, 1937. The hearing was set for the latter part of November and by agreement of counsel it was set over until December 6th.

Rule 10 of this court provides that it shall be the duty of appellant to file a praecipe indicating the portions of the record to be incorporated into the transcript. No such praecipe was filed by plaintiff-respondent nor even a letter written suggesting what, if any, portions of the record should be eliminated.

The rules provide a method by which appellant can enforce the printing of a proper record if the appellee objects to the praecipe. Equity Rule 75 as amended May 31, 1932.

It is submitted that, if counsel for petitioner-appellant had desired to have the record reduced, it was his duty to submit the praecipe required by the rules, and having failed to do so, he cannot cast upon counsel for the defendant-appellee the onus of presenting an alleged unnecessarily large record to this Court.

It is submitted that for the reasons pointed out in the motion filed by the defendant-respondent the motion should be granted.

Dated, New York, May 25th, 1938.

Respectfully submitted,

WILLIAM E. WARLAND,
FRANCIS H. WARLAND,
NATHANIEL L. LEEK,
Counsel for Defendant-Respondent.

IN THE

Supreme Court of the United States

OCTOBER TERM, 1937.

No. 72.

CROWN CORK & SEAL CO., INC., *Plaintiff-Petitioner,*

v.

FERDINAND GUTMANN & COMPANY, *Defendant-Respondent.*

OPPOSITION TO RESPONDENT'S MOTION TO AMEND JUDGMENT.

Petitioner opposes the Motion to Amend Judgment in this case and submits that it should be denied.

The case came before this Court on writ of certiorari to the Circuit Court of Appeals for the Second Circuit, which had held the Warth divisional patent No. 1,967,195 invalid for laches.

This Court held that there was no laches and reversed the judgment.

In accordance with Rule 32, paragraph 3,[1] of this Court and long established practice, the costs were awarded to petitioner in the decree of this Court dated May 2, 1938.

---

[1] Rule 32, Par. 3:

"In cases of reversal of any judgment or decree by this court, costs shall be allowed to the appellant or petitioner, unless otherwise ordered by the court. The cost of the transcript of the record from the court below shall be a part of such costs, and be taxable in that court as costs in the case."

Substantially the same rule has been in effect since 1838. See the discussion of the rule history in *St. Louis et al.* v. *Spiller*, 275 U. S. 156, 159-160.

During all of the years that this rule has been in force, it has been the practice of this Court to award costs to the appellant or petitioner who obtains a reversal. So far as counsel for petitioner have been able to ascertain, the only instances in which the Court has availed itself of the clause "unless otherwise ordered by the Court" (Rule 32) are cases where there has been an affirmance in part and a reversal in part. This case does not present that question, since here the reversal was complete.

Requesting an exception to the general rule, respondent asserts: (a) it may eventually prevail in the lower court on issues not there decided or here reversed, and, (b) in the lower courts only a completely successful party may recover costs.

The Final Outcome of the Case is Not Material to the Award of Costs in this Court.

As early as 1842, this Court in *Bradstreet* v. *Potter*, 41 U. S. (16 Pet.) 317, 318, 10 L. Ed. 978, 979, awarded costs to the petitioner upon reversal of the lower court where there remained issues to be decided by the lower court, which issues had not properly been brought before the Supreme Court. A question presented was as to whether the defendant in error should be subjected to costs if no judgment was given by this Court on the merits of the cause. After refusing to decide the merits of the case, the Court said:

> "In respect to costs upon cases brought to this Court, the rule is, as may be seen in the forty-seventh rule of the Court prefaced to 8 Peter's Reports, that in all cases of reversals of any judgment or decree in this Court, except where the reversal shall be for want of jurisdiction, costs shall be allowed in this Court for

the plaintiff in error, or appellant, as the case may be, unless otherwise ordered by the Court.

"The question as to costs in the Circuit Court is not before us."

In *Baldwin* v. *Ely*, 9 How. 580, 602, 13 L. Ed. 266, 275, this Court reversed a decree of the Circuit Court and remanded the case with directions as to further procedure in conformance with the opinion. In view of the facts of the case, the Court held that the appellee was entitled to his costs in the Circuit Court, stating however:

> "But as regards the costs in this Court, the appellant, by the established rules and practice of the Court, is entitled to recover them, and they must be charged against the appellee."

In both of the above cited cases, this Court was fully aware that further proceedings were to be had in the lower courts but made it clear that costs in this Court and costs in the lower court are independent questions.

Aside from the plain language of the rule, the award of costs to petitioner is pursuant to the mandatory provision of statute[2] insofar as the printing of the record is concerned. The printing of the record in the case at bar is the principal item of expense. This Court has repeatedly recognized the force of the statute quoted footnote *infra*.

Indianapolis & St. Louis Railroad Co. v. *Vance*, 96 U. S. 594, 595, 24 L. Ed. 825.
Fairmont Creamery Company v. *State of Minnesota*, 275 U. S. 70, 77.

---

[2] U. S. C., Title 28, Section 352 (Judicial Code Section 254):

"There shall be taxed against the losing party in each and every cause pending in the Supreme Court, the cost of printing the record in such case, except when the judgment is against the United States."

There Should Be No Exception to the General Rule Because of Respondent's Insistance Upon Printing Irrelevant Portions of the Record.

As the motion admits, the only portion of the Circuit Court of Appeals' decision which this Court was asked to review related to the Warth Reissue Patent 19,117 and the divisional patent No. 1,967,195.

The record related to five other patents and it became necessary to reprint the same for use in this Court. Petitioner therefore proposed to respondent that all parts not pertinent to the petition for certiorari be eliminated. Respondent refused, as shown by the affidavit of petitioner's counsel reproduced in the appendix and filed with the clerk.

Thus the major portion of the record constituting three volumes of 1843 pages was irrelevant to the issues petitioner presented.

Under such circumstances respondent has no equities which invite an exception to the general rule.

The obligation of a party in respondent's position to bear the costs of unnecessary printing has been recognized by this Court.

In *The Ball and Socket Fastener Company* v. *Kractzer*, 150 U. S. 111, 118, 37 L. Ed. 1019, 1021, the Court said:

> "We are, therefore, of opinion that the court below committed no error in its disposition of the case; but in view of the fact that the appellee has seen fit to encumber the record with copies of some fifty immaterial patents, we think it a proper case for the application of the 10th Rule,[3] which authorizes us (¶ 9) to impose costs upon an appellee guilty of requiring unnecessary parts of the record to be printed, and that he should be charged with half the cost of printing the record in this case. 'Care should be taken that costs are not unnecessarily increased by incorporating useless papers, and that the case is presented fairly and intelligently.' *Union Pac. R. Co.* v. *Stewart*, 95 U. S. 279, 284 (24: 431, 432). With this qualification the decree is affirmed."

[3] The rule referred to in the decision corresponds substantially to present Rule 13 (9).

Again in *Stevens* v. *White City*, 285 U. S. 195, 204, 76 L. Ed. 699, 704, where the Court, on certiorari, affirmed the decision of the Court below, the opinion states:

> "We find that respondent caused unnecessary parts of the record to be printed amounting in all to 186 pages. This is admitted in a statement filed by counsel for respondent. The cost of such printing will be charged to respondent. Rule 13, ¶ 9".

In view of the Court's admonition against unnecessarily increasing the cost, it is submitted that the circumstances of this case did not warrant a request on the part of the respondent for an exception to the rule that costs should be awarded to a petitioner where a reversal is obtained.

Respondent's Reference to the Practice in the State Courts is Irrelevant.

Respondent asserts that the New York State Appellate Courts frequently direct that costs shall abide the event and that "it is the practice of the federal courts to follow that of the state courts." This assertion is beside the point here presented. In any event, the decisions cited below show that the *federal* courts, including the Circuit Court of Appeals for the Second Circuit, award costs incurred with respect to an appeal regardless of the final outcome.

Land Oberoesterreich v. *Gude*, (C. C. A. 2nd), 93 F. 2nd, 292, 293.
Berthold v. *Burton*, (C. C. S. D. N. Y.), 169 Fed. Rep. 495, 496.
Jennings v. *Burton*, (C. C. S. D. N. Y.) 177 Fed. Rep. 603.
Miller v. *Hartwell Co.*, (C. C. A. 5th) 271 Fed. Rep. 385, 390.
Bailey v. *Mississippi Home Telephone Co.*, (D. C. M. D. Penn.) 254 Fed. Rep. 358.

It is to be noted that in the *Land Oberoesterreich case* (*supra*) the Court of Appeals for the Second Circuit or-

dered a new trial, yet awarded costs regardless of the final outcome.

Respondent asserts (Motion p. 4) that the position of the parties in the case at bar "is similar to a case in which an unsuccessful party takes an appeal and a new trial is ordered." Even accepting respondent's own assertion, the *Land Oberoesterreich* case shows that in accordance with the practice of the federal courts petitioner is entitled to costs without regard to the final outcome.

We find nothing in the patent cases cited by respondent (Motion p. 4) having any bearing on the question presented by the motion.

Respectfully submitted,

THOMAS G. HAIGHT

APPENDIX.

Affidavit of Walter A. Pauling.

STATE OF NEW YORK }
COUNTY OF NEW YORK } ss:

WALTER A. PAULING being duly sworn deposes and says that he is an attorney associated with the firm of Gifford, Scull & Burgess solicitors for the Crown Cork & Seal Co., Inc., the plaintiff-petitioner; that on or about October 11, 1937 after the grant of the petition for writ of certiorari and when it became necessary to print the transcript of record for filing and use in this Court, deponent, in a telephone conversation with Wm. E. Warland, Esq., counsel for the defendant-respondent, requested Mr. Warland to stipulate to eliminate all parts of the record not pertinent to the issues raised by plaintiff's petition for certiorari; that Mr. Warland stated that he would not agree to eliminate anything but desired to have the entire transcript of record reproduced; that, to confirm the conversation and understanding, a letter, of which the annexed is a copy, was sent to Mr. Warland on October 22nd, 1937.

WALTER A. PAULING.

Subscribed and sworn to before me this 18th day of May, 1938.

AGNES E. CONNEEN,
Notary Public.

Copy.

William E. Warland, Esq.,
Hauff & Warland,
41 Park Row,
New York, N. Y.

My dear Mr. Warland:

CROWN CORK & SEAL v. GUTMANN

This is to confirm the understanding reached between you and our Mr. Pauling as to the record in the Supreme Court in the above.

We proposed to you that in reproducing the record for the Supreme Court, all parts thereof not pertinent to the issues before the Supreme Court should be eliminated from the record by stipulation but you decided that you wanted the entire record reproduced.

Accordingly the Clerk has been instructed to reproduce the entire record before the Court of Appeals.

Yours very truly,

GEORGE F. SCULL (Signed)

GFS*C

P.3

SUPREME COURT OF THE UNITED STATES.

No. 72.—October Term, 1937.

Crown Cork & Seal Company, Inc., Petitioner, *vs.* Ferdinand Gutmann Co., Inc.	On Writ of Certiorari to the United States Circuit Court of Appeals for the Second Circuit.

[May 2, 1938.]

Mr. Justice Butler delivered the opinion of the Court.

Petitioner sued respondent in the district court for eastern New York to enjoin infringements of patents, two of which are here involved. One is Warth Reissue Patent, No. 19,117, dated March 20, 1934. The other is Warth Patent, No. 1,967,195, dated July 17, 1934, a divisional patent. Both relate to methods for applying small disks of paper or foil, known as center spots, to cork cushions of crown caps. These caps are used to seal bottles containing pressure beverages. The center spot prevents contact of the liquid with the cork. The district court adjudged both patents valid and infringed. 14 F. Supp. 255. The circuit court of appeals reversed, holding the reissue patent not infringed and the divisional one invalid because of laches in filing the application on which it was granted. 86 F. (2d) 698.

The questions presented by the petition for the writ, granted — U. S. —, are these:

1. "Does this Court's decision in *Webster Co.* v. *Splitdorf Co.* [264 U. S. 463] mean that, even in the absence of intervening adverse rights, an excuse must be shown for a lapse of more than two years in presenting claims in a divisional application regularly filed and prosecuted in accordance with patent office rules"?

2. "Where there has been more than two years delay in asserting specific claims in a divisional application, is it an excuse for the delay that there were claims in the parent patent which, on their face, covered and were reasonably believed to cover, the subject-matter of the divisional claims, even if a Court later interpreted the parent patent claims not to cover such subject-matter?"

Our consideration of the case will be limited to these questions. *Washington Coach Co.* v. *Labor Bd.*, 301 U. S. 142, 146. *Morehead* v. *N. Y. ex rel. Tipaldo*, 298 U. S. 587, 604, 605. *Clark* v. *Williard*, 294 U. S. 211, 216. *Alice State Bank* v. *Houston Pasture Co.*, 247 U. S. 240, 242. The first calls for decision upon a single point. It specifically assumes the absence of intervening rights and that the application was appropriately made. There is no question as to the validity of either the original or reissue patents.

Warth filed his first application January 7, 1927 and his second November 7, 1930.[1] From these came the original patent, January 6, 1931. It was to correct an error in the specification that the reissue patent was granted. Before issue of the original patent Johnson, November 26, 1929, filed application on which a patent issued April 5, 1932. April 4, 1933, two years and four months after the original patent was granted Warth, he carved from his second application a divisional one in which he copied the claims of the Johnson patent. In the interference declared upon the conflict, the patent office held Warth's divisional application entitled to the filing date of his first one, and awarded the claims of the Johnson patent to him as prior inventor. These are the claims held too late by the circuit court of appeals.

The claims of the reissue patent involved are shown in the margin.[2] The important feature is simultaneous application of pressure and heat to the center spot to make it stick to the cork cushion in the cap. Neither these nor any other claims of the patent specify

[1] The first application extended to materials to be used in making center spots as well as to methods for applying them. The second application, because of a requirement of the patent office, omitted disclosures as to materials but included those as to methods that the first contained.

[2] Claim 1. "The improved method of manufacturing caps of the type having an interior disc of cushion material provided on its exposed face with a center spot, which comprises providing spot material in strip form having one surface formed of an exposed continuous coating of water resistant adhesive which is normally hard at room temperature but becomes tacky upon the application of heat and having another surface to be exposed to the contents of a capped container, cutting from said strip a facing spot having one surface completely coated with said adhesive with a cap disposed beneath the portion of the strip from which the spot is cut, whereby the cutting operation positions the spot upon the cushion material with the coating between the spot and the cushion material, and upon assembly applying simultaneously to the spot pressure and sufficient heat to render the adhesive tacky, thereby causing the spot to adhere to the cushion material, and thereafter permitting the adhesive to cool and harden."

Claim 3 repeats the words of claim 1 and adds these words, "while subjecting the assembled unit to pressure."

means to be employed to furnish the heat. The claims in suit of the divisional patent[3] cover means to supply heat to be applied to the center spots when subjected to pressure. The important feature is "heating the pads [cork cushions] in the caps" before placing the spots upon them.

The first application, January 7, 1927, stated: "It may be desirable to secure the metal foil spot in position, prior to the heat and pressure steps, sufficiently to prevent dislodgement of the spot during any interval between assembling and final sticking. This may be accomplished, for example, by preheating the assembled crown, to soften the coating as soon as the metal foil spot is deposited." That application contained claims, construed by the circuit court of appeals to be broad enough to cover that disclosure. The patent office called for drawings to illustrate means for carrying out the method claimed. Accordingly, Warth showed, by way of illustration, that heat might be furnished by the punch used to cut the spots from the adhesive material and place them upon the cork in the cap, where by the same stroke of the plunger, they might be subjected to pressure. When he filed the drawings, December 3, 1930, he canceled from the first application the statement just quoted and canceled the claims originally filed. The second application had already been filed. Both contained another statement: "In carrying out the invention according to what is now considered the best practice, the coating will be softened by heat after the crown is assembled. This may be accomplished in any suitable manner, as by a heated plunger or a plunger and heated table. The heat softens the coating and renders it adhesive. . . . " So far as concerns the question under consideration,

[3] These claims are fully indicated immediately below. The insertions in brackets give equivalent terms used in the claims of the Reissue patent.

Claim 1. "The method of assembling linings [center spots] for sealing pads [cushion material] in ~~respectable~~ receptacle closure caps, consisting in providing caps with sealing pads therein and a web of lining material arranged with an adhesive surface non-viscous at normal temperature, heating the pads in the caps, severing linings from the web of lining material and assembling the linings as they are severed from the web in the caps with the adhesive surface in contact with the heated pads to render the adhesive viscous and effect adhesion of the linings to the pads."

Claim 2 repeats the words of claim 1 and adds these words, "and then placing the linings in the caps under heat and pressure to effect an intimate adhesion between the linings and pads."

Claim 3 repeats the words of claim 1 and the addition of claim 2 and adds these words, "and then placing the linings assembled in the caps under pressure during the cooling thereof."

it is broad enough to include means for supplying heat by the punch as shown by the drawings, and the preheating method claimed in the divisional application.

The district court found no adverse use of the preheating method prior to the filing date of the application for the reissue patent. The circuit court of appeals did not disturb that finding. It found that Warth's disclosure of the preheating method was continuously before the patent office from the date of his first application, but that there was no claim for the preheating method on file from December 3, 1930, until April 4, 1933, when he filed application for the divisional patent. It held, citing *Webster Co.* v. *Splitdorf Co., supra,* that *prima facie* the two year limit applies to divisional applications, and that an applicant who waits longer before claiming an invention disclosed in his patent must justify his delay by proof of some excuse. It said (86 F. (2d) 702), "No such excuse appears here. Had Warth chosen to retain in his parent application broad generic claims which might cover the preheating method, then indeed the Splitdorf rule might not be applicable . . . But . . . for a period of more than two years Warth apparently did not wish to claim the preheating method, having deliberately canceled the preheating specification from his original application and shaped his claims so as to exclude it and his patent having been granted January 6, 1931. He made no claim for preheating until more than two years thereafter, namely, April 4, 1933. In the meantime a patent containing claims for the preheating method had been granted to Johnson on April 5, 1932, and it was Warth's discovery of this fact which stirred him to action. As in the *Splitdorf* case, had it not been for this competitor, Warth might never have considered the subject worth claiming as an invention." The court meant that Warth had really abandoned his invention. See *Western Electric Co.* v. *General Talking Pictures Co.,* 91 F. (2d) 922, 927.

But, as abandonment was not pleaded as a defense, R. S. § 4920, and as Warth's disclosure was continuously before the patent office, clearly without any significance adverse to the petitioner is the fact that Warth formally canceled one disclosure from his first application and with it claims thought by the circuit court of appeals broad enough to cover the disclosure. The continuity so maintained shows that Warth intended to retain, not to abandon, the disclosed inven-

tion. See *Godfrey* v. *Eames*, 1 Wall. 317, 325-326. *Clark Blade & Razor Co.* v. *Gillette Safety Razor Co.*, 194 Fed. 421, 422.

This case is not like *Webster Co.* v. *Splitdorf Co., supra.* In that case, there came here the question of the validity of claims of a patent issued to Kane in 1918. In 1910 Kane had filed his first application, on which patent issued in 1916. In 1913 a patent covering the same subject-matter issued to the Podlesaks, to whom a reissue patent was granted in 1915. Later in 1915, Kane filed a divisional application which copied the claims of the Podlesak patent. They were decided in favor of the Podlesaks. Thereafter, June 17, 1918, Kane amended his divisional application by adding claims which were allowed, and September 24, 1918, patent issued to Webster Electric Company, Kane's assignee. In 1915, it had brought the suit against the Splitdorf Company. October 25, 1918, it filed a supplemental bill bringing in claims of the patent issued September 24, 1918.

This Court pointed out (p. 465) that the claims in question "were for the first time presented to the Patent Office, by an amendment to a divisional application eight years and four months after the filing of the original application, five years after the date of the original Podlesak patent, disclosing the subject matter, and three years after the commencement of the present suit." We suggested that it was doubtful whether the claims were not so enlarged as to preclude allowance under the original application; we found that Kane, deeming their subject-matter not invention, did not intend to assert them, and, prior to 1918, did not entertain an intention to have them covered by patent. During all of this time their subject matter was disclosed and in general use; Kane and his assignee simply stood by and awaited developments. It was upon the reasons so stated that this Court declared (p. 466) "We have no hesitation in saying that the delay was unreasonable, and, under the circumstances shown by the record, constitutes laches, by which the petitioner lost whatever rights it might otherwise have been entitled to."

Upon a review of earlier cases we condemned the lower court's statement (283 Fed. 83, 93) that *Chapman* v. *Wintroath*, 252 U. S. 126, fixed the time within which application for a divisional patent might be made at two years from date of the issue of the parent patent. We showed that the *Chapman* case held that an inventor,

whose application disclosed but did not claim an invention later patented to another, was not required within one year after issue of the other patent, to file divisional application claiming the invention and so to raise issue of interference, but that, by analogy, the two-year period under R. S. § 4886[4] applied rather than the one-year period of R. S. §4894,[5] and that the opinion did not fix a hard and fast rule to be applied in every case of a divisional application. Then we said (p. 471): "Our conclusion, therefore, is that, in cases involving laches, equitable estoppel, or intervening private or public rights, the two-year time limit *prima facie* applies to divisional applications, and can only be avoided by proof of special circumstances justifying a longer delay. In other words, we follow in that respect the analogy furnished by the patent reissue cases." That statement is not directly applicable to the precise question of laches upon which the case turned, but was made in reference to the question arising upon the lower court's erroneous interpretation of *Chapman* v. *Wintroath*. See *Wagenhorst* v. *Hydraulic Steel Co.*, 27 F. (2d) 27, 29-30. *Wirebound Patents Co. et al.* v. *Saranac*, 37 F. (2d) 830, 840-841. *Utah Radio Products Co.* v. *Boudette*, 78 F. (2d) 793, 799. It is clear that, in the absence of intervening adverse rights, the decision in *Webster Co.* v. *Splitdorf Co.* does not mean that an excuse must be

[4] R. S. § 4886, as amended March 3, 1897 (29 Stat. 692): "Any person who has invented or discovered any new and useful art, machine, manufacture, or composition of matter, or any new and useful improvements thereof, not known or used by others in this country, before his invention or discovery thereof, and not patented or described in any printed publication in this or any foreign country, before his invention or discovery thereof, or more than two years prior to his application, and not in public use or on sale in this country for more than two years prior to his application, unless the same is proved to have been abandoned, may, upon payment of the fees required by law, and other due proceeding had, obtain a patent therefor." [The statute has since been amended, but not to change the two-year period. See 35 U. S. C. § 31.]

Cf. R. S. § 4887 (35 U. S. C. § 32), relating to inventions patented abroad; R. S. § 4897 (35 U. S. C. § 38), relating to renewal application after failure to comply with requirement as to payment of final fee; R. S. § 4920 (35 U. S. C. § 69), relating to defense of prior invention.

[5] R. S. § 4894, as amended March 3, 1897 (29 Stat. 693). "All applications for patents shall be completed and prepared for examination within one year after the filing of the application, and in default thereof, or upon failure of the applicant to prosecute the same within one year after any action therein, of which notice shall have been given to the applicant, they shall be regarded as abandoned by the parties thereto, unless it be shown to the satisfaction of the Commissioner of Patents that such delay was unavoidable." [The statute has since been amended to reduce the period to six months. See 35 U. S. C. § 37.]

shown for a lapse of more than two years in presenting the divisional application. Where there is no abandonment, mere delay in filing a divisional application for not more than two years after an intervening patent or publication, does not operate to enlarge the patent monopoly beyond that contemplated by the statute. By R. S. § 4886, delay in filing an application for not more than two years after an intervening patent or publication does not bar a patent unless the invention "is proved to have been abandoned." See *Wirebound Patents Co., et al.* v. *Saranac*, 37 F. (2d) 830, 840, 841; 65 F. (2d) 904, 905, 906. And, as none need be shown, there is no occasion to decide whether the facts stated in the second question are sufficient to constitute an excuse for the delay referred to.

As our decision is limited to the first question presented, the judgment of the circuit court of appeals will be reversed and the case will be remanded to that court for decision of the other issues in the case in accordance with this opinion.

It is so ordered.

Mr. Justice CARDOZO and Mr. Justice REED took no part in the consideration or decision of this case.

SUPREME COURT OF THE UNITED STATES.

No. 72.—October Term, 1937.

Crown Cork & Seal Company, Inc., Petitioner, *vs.* Ferdinand Gutmann Co., Inc., Respondent. | On Writ of Certiorari to the United States Circuit Court of Appeals for the Second Circuit.

[May 2, 1938.]

Mr. Justice Black, dissenting.

This Court declared in *Webster Co.* v. *Splitdorf Co.*, 264 U. S. 463, 466, 471:

"In suits to enforce reissue patents, the settled rule of this Court is that a delay for two years or more will 'invalidate the reissue *unless the delay is accounted for and excused by special circumstances, which show it to have been not unreasonable.*' . . .

"Our conclusion, therefore, is that in cases involving *laches, equitable estoppel or intervening private or public rights,* the two year limit *prima facie applies to divisional applications* and can only be avoided *by proof of special circumstances justifying a longer delay.* In other words, we follow in that respect the analogy furnished by the patent reissue cases." (Italics supplied.)

The rule announced in the *Splitdorf* case was based upon a long line of decisions of this Court extending from *Miller* v. *Brass Co.*, 104 U. S. 350, decided in 1882.

The majority opinion abandons the principle of the *Splitdorf* case that either laches *or* equitable estoppel *or* intervening private rights *or* intervening public rights—in the absence of *proved special circumstances*—bars a divisional patent after a lapse of an unreasonable length of time—*prima facie* two years. It is now held that neither laches nor equitable estoppel may alone invalidate a patent without proof of "intervening adverse rights." The authorities relied on in the *Splitdorf* case emphasized the right of the public—apart from provable adverse use by individuals—to require an applicant to pursue his right to a patent diligently and

without enlargement of claims *after filing an original application.*[1] "Any practice by the inventor and applicant for a patent through which he deliberately and without excuse postpones beyond the date of the actual invention, the beginning of the term of monopoly, and thus puts off the free public enjoyment of the useful invention, is an evasion of the statute and defeats its benevolent aim."[2]

There is a further departure from the *Splitdorf* case in the holding that two years delay in filing a divisional application after an intervening patent does not—*in the absence of actual abandonment of the invention*—bar the right to a "divisional" patent. Abandonment is but one of many grounds for invalidating a patent. Equitable estoppel, intervening public rights, or unjustified and unexplained laches were considered in the *Splitdorf* case and cases there relied on to be individually sufficient bars, without proof of abandonment. Unjustified delay and abandonment are separate defenses. If proof of abandonment is to be a prerequisite, laches as a separate defense is destroyed, although it has been recognized for more than fifty years. Unreasonable delay which serves to postpone the beginning of the seventeen year monopoly limitation, not only is possible without abandonment of the invention, but is highly probable. With the destruction of the defense of laches the public loses the benefit of the principle that "An inventor *cannot without cause* hold his application pending during a long period of years, leaving the public uncertain, whether he intends ever to prosecute it, and keeping the field of his invention closed against other inventions."[3]

The Court of Appeals following this settled principle—now abandoned—said:[4] "We think they [claims in the patent] are invalid for *laches in filing the application for them.* (Citing *Webster Co.* v. *Splitdorf Co.*). . . . These circumstances [facts of this case] invite operation of the two year limitation designed to protect the public against obtaining in effect an extension of a patentee's monopoly *by apathy and unexcused delay* in bringing

forward by divisional or reissue applications claims broader than those originally sought." (Italics supplied.)

While "divisional" applications have never been expressly authorized by statute the courts have long recognized their use as a part of Patent Office procedure. Petitioner's patent which the Court of Appeals found barred by laches was granted on a "divisional" application. Patent Office regulations which have limited each application for a patent to a single invention and have required a "division" of an application containing claims for two separate and distinct inventions, apparently gave rise to the procedural device of "divisional applications." The Court of Appeals of the District of Columbia acting in a special appellate capacity[5] and the Patent Office, have treated a "divisional," properly used, in some respects, as a substitute for an amendment. In accordance with this conception "divisionals" have been for certain purposes, treated as "continuations" of original applications and given the priority of original applications. The logical conclusion was reached that after an original application merged in a patent, a "divisional" application could not be attached to, or considered as a "continuation" of it, because "there was nothing to be continued."[6] After a patent is granted it passes "beyond the control and jurisdiction" of the Patent Office; the proceedings are closed and the application can neither be amended nor serve as the basis for a new "divisional" or "continuing" application.[7]

Here an application for a process patent was filed in 1927. November, 1930, in response to Patent Office requirement, a "divisional" application was filed for a *product* patent. January, 1931, a process patent was granted on the original application. More than two years after the original application had merged into a process patent another application designated as a "divisional" was

filed (April 4, 1933), for a second process patent—here involved. The Court of Appeals found this delay of six years to be without justification or excuse. Disregarding the previously recognized requirement that justification and excuse must be proven for such delay, the majority now hold that an applicant can, for six years, delay his claim for an alleged discovery without excuse, justification, or reason for the delay. This is permitted despite the fact that unclaimed disclosure of the alleged invention had been made in the 1927 process application and in the 1930 product application.

Congress—given the power by the Constitution—has fixed the statutory limit of a patent monopoly at seventeen years.[8] By the procedural device of a "divisional" application, designed to protect rights granted an inventor by statute, petitioner has carved for itself priority monopoly rights, beginning in 1927 and lasting until 1951—twenty-four years, or seven years more than Congress has authorized.

In the remedy of reissue provided by statute for applicants whose claims fail to protect their entire discoveries,[9] Congress has been alert to protect the public from such an extension of monopoly. A reissue patent must be based on oath that an applicant's original patent failed to cover its actual invention as a result of accident, inadvertence or mistake, and runs only *for the unexpired portion of a seventeen year patent grant.* The use of "divisionals" or "continuations," no longer subject to the defense of laches or unreasonable delay, will permit an applicant to obtain, by a non-statutory procedural device, monopoly privileges denied by the reissue statute.

The essential additional claim in petitioner's 1934 "divisional" patent was only mentioned in the 1927 original application and the 1930 "divisional" application by way of casual suggestion and incidental illustration.[10] Even this casual suggestion was stricken from the 1927 application in December, 1930. These suggestive

[9] 35 U. S. C., Chapter 2, Sec. 64.

[10] The essential additional claim of the 1934 divisional process patent was for "preheating" cork used in making bottle caps. The incidental reference to preheating in the 1927 application was as follows:

"It *may* be *desirable* to secure the metal foil in position, prior to the heat and pressure steps, sufficiently to prevent dislodgment of the spot during any interval between assembling and final sticking. This *may be accomplished, for example,* by preheating the assembled crown, to soften the coating as soon as the metal foil spot is deposited. Or the coating *may be, softened* by moistening slightly with a solvent, such as benzol. In either case the coating

illustrations did not constitute parts of the inventions which the 1927 and 1930 applications sought to cover or secure.[11] The speculative suggestions—from separate applications for different inventions—are pieced together and held sufficient to "continue" the 1927 application (after its merger in a patent) and the 1930 application, as support for the retroactive operation of a claim made for the first time in 1933. As a result of the destruction of the defense of laches in applying for "divisional" applications, those familiar with a given field of industry may now insert speculative conjectures as disclosures in various applications and permit them to lie dormant until a competitor reduces speculation to practicality. Then, by the device of a "divisional," or if need be, as here, by "divisional" on "divisional," such a competitor can be pursued with infringement suits and harassed into surrendering his business to an ingeniously dilatory applicant.[12] Thus, sweeping, indefinite and unclaimed disclosures, and adroit use of "divisionals" —which laches and unreasonable delay are no longer sufficient to bar—are permitted to extend a patent's statutory life and to increase a patentee's reward beyond that granted by Congress.

" 'The patent laws are founded in a large public policy to promote the progress of science and the useful arts. The public, therefore, is a most material party to, and should be duly considered in, every application for a patent. . . . But the arts and sciences will certainly not be promoted by giving encouragement to inventors to withhold and conceal their inventions for an indefinite time, or to a time when they may use and apply their inventions to their own exclusive advantage, irrespective of the public benefit, and certainly not if the inventor is allowed to conceal his invention to be brought forward in some after time to thwart and defeat a more diligent and active inventor, who has placed the benefit of his invention within the reach and knowledge of the public.' "[13]

---

becomes tacky enough to hold the metal foil from getting out of position during ordinary passage through assembling apparatus."

The 1930 divisional application for a product patent merely suggested that "*It may be desirable* to secure the spot in position, prior to the heat and pressure steps, sufficiently to prevent dislodgement of the spot during any interval between assembling and final sticking. *This may be accomplished*, for example, by preheating the assembled crown, to soften the coating, as soon as the metal foil is deposited."
